Of course, we recognize the urban influence of crowding, inadequate housing, poverty, etc., but this is not sufficient to account entirely for the rate in Detroit. We must consider the effect of the racial stocks represented in the population. Of course, Detroit is a city of enormous industrial growth in the past 25 years and has attracted a great alien population. Thousands of Canadians largely of British stock have come into Detroit, as well as other nationalities. Dublin has pointed out that in New York and Pennsylvania the rate among the English and Irish was higher than it was for native whites; the Austrian, Russian and Italian rates were lower. He says, speaking of the marked difference in the rate of mortality which prevails in the various nativity groups composing the population of the country, "It is difficult for anyone confronted with these facts to escape the conclusion that an inherited racial immunity is a factor in the development of tuberculosis."

The racial factor, we believe, is also an explanation in a measure of the higher rate in the Upper Peninsula. There the factors of urban congestion and sanatoria of wide influence are not present, and the same period that has seen the great growth in Detroit has seen a wide immigration into the Upper Peninsula of foreign race stocks. This is particularly true of what is known as the mining districts where there are large numbers of Finns.

By the census of 1920 Michigan had a foreign born white population of 19.8 per cent. Every county in the Upper Peninsula (15 in all) with the single exception of Mackinac County, with 18.9 per cent foreign born white, has a percentage greater than that for the state, running as high as 37 per cent in Gogebic County. Of the 68 counties in lower Michigan, only 7 showed a rate exceeding that for the state. All but one of these were rural counties ranging from 20 per cent to 22.9 per cent. Wayne County had 29.3 per cent foreign born white in its population, and in Detroit there was 33.6 per cent of the population foreign born and we believe this explains in a measure the high tuberculosis rate for Detroit and Wayne County.

However, it would not be fair to take out Detroit without consideration of the effect on some of the other large cities such as Grand Rapids. Here the Holland Dutch are concentrated, and the county group rate is not affected. Detroit is the only city where the concentration of foreign born is so great that the county rate is increased because of it.

Despite the supposed Dutch population in Grand Rapids, the percentage of foreign born population in that city was only 25.2 per cent in 1920 and the foreign population of Flint and Lansing is 17.3 and 12.7, respectively, even below the state rate of 19.8. So if we consider

these other cities separately the county rate would not change appreciably.

Let us see, however, how the foreign population element in each county group compares with the tuberculosis rate, using the 1920 figures. The group in the Upper Peninsula with the highest percentage of foreign born population also shows the highest tuberculosis rate. Table II shows the percentage of foreign born white population in correlation with the tuberculosis rate:

TABLE II

District	Per cent of Foreign born white	Tuberculosis Rate
Upper Peninsula	28.8	103.7
Southern Counties	20.9	92.9
Central Counties	15.8	68.2
Northern Counties	15.7	77.6
State	19.8	85.8

Now we have already shown that the Upper Peninsula rate is high, due, we believe, to the foreign element. Let us analyze the composition of that foreign population and see how the rate varies for the several racial stocks.

The rate for some races is even below that for the United States and if those races predominate in the Upper Peninsula then our reliance on an alien element to explain the tuberculosis rate is unwarranted (See Table III).

TABLE III

COUNTRY OF BIRTH

Upper Peninsula rate 1920	98.6
Finland	260.0
Austria-Hungary	203.8
Sweden	154.4
Germany	80.1
Canada	59.8
England	41.8
Italy	38.1
Russia and Poland	34.0
Indian, Negro and Other	223.9
Native White	86.4

The rates for 5 of the races are below that for native white but each of these groups constitutes less than 2 per cent of the total population, except the Canadians. The races with the higher rates form a larger part of the population. The Finns, with a rate of 260.0, form only 8 per cent of the total population, yet they had 20 per cent of the tuberculosis deaths. The Scandinavians are another large element among the alien group while the stocks with the lower death rates make up, with the single exception of the Canadians, but small percentages of the total population. Of course, it must also be borne in mind that where the

foreign element bulks large in the total population, then the so-called native born white class includes many who are only first generation Americans. This is particularly true of the Finns, there being many who are classed as native white which the death records show to be the children of parents who were born in Finland.

Of course, any racial tendency toward tuberculosis would not be eradicated by such an accident as American birth and that may explain why the native white Upper Peninsula rate of 86.4 is even slightly above the rate of 85.8 for the entire state. The true native white rate would undoubtedly be much less.

While the negro population is small in the Upper Peninsula there are many Indians and it is a known fact that the Indian rate from tuberculosis is enormously high.

We fully realize the importance of age in this disease but a limited study indicates that this factor is too complicated to present here.

Many writers have mentioned the factor of general economic prosperity and its effect on the tuberculosis death rate, but because of the economic adjustments occurring all the time it is quite useless to take any one year and say, "Well, here is a high rate; probably due to a panic in Wall Street." The only thing we can say with certainty is that as the general standard of living has gone up, the tuberculosis rate has gone down. This is true despite the fact of the tremendous influx of aliens into Detroit and the other automobile producing centers to meet the demands of the automobile trade since 1901.

The rates for our 4 groups have decreased and we may say the general causes are, first, an increase in economic prosperity; second, the tuberculosis campaigns.

We might also conclude that the reason that the Upper Peninsula and southern counties have not decreased as rapidly as the other districts is because of the influx of foreign population into these districts, and the predominating races are from those countries where tuberculosis rates are higher than they are in the United States.

The general economic level of our state has risen in the past 25 years and we believe that this has had much to do with the declining tuberculosis rate, but further than this we can appraise the economic factor in greater detail and see its relation to the tuberculosis rate.

Korosi says, "Of the inhabitants of Budapest there die of consumption in every 10,000 well-to-do persons, 40; moderate well-to-do, 62.7; poor, 77.7; and paupers, 97." While no figures are available on the economic status of our Michigan deaths we would point out the fact that the higher rates are in Detroit and the Upper Peninsula where concentration of the foreign born is greater.

Little need be said about the relation between the standard of living and foreign stock. It is evident to all social workers that alien races are apt to be the ones living in crowded homes, with little ventilation, raising underfed children and unable to feel the need of or to pay for proper medical attention. The factor of an inherent susceptibility to tuberculosis in certain racial stocks is not the whole explanation. The economic feature must be considered. The foreigner comes to us and starts in under difficulty. He does not get a high wage and his living is not and cannot be on as high a scale as that of the native stock and so tuberculosis has a better opportunity to work its ravages on him.

To be sure, some races do have a lower rate, as Dublin has shown, but the English rate was fairly high. However, we found that the English and Canadian rates for the Upper Peninsula were lower than for native whites. This is exactly in accord with our premise about the economic well-being of foreign stocks. The Canadian is not so handicapped as the others, being familiar with our language and customs. He can get a better job and that means better living and more wholesome food for the building of sound bodies with which to withstand tuberculosis.

In the second place, undoubtedly, the organized effort to combat tuberculosis has contributed materially to the falling death rate. By the Michigan tuberculosis campaign we mean the efforts of all the societies, both clinical and educational, of the county and state, the state health department and also the work of the various sanatoria throughout the state. The results of this work in all its ramifications are so varied that any attempt to examine the many angles of the work or to correlate the efforts with any other rate would probably be misleading and a waste of time.

We can, however, outline in a general way the work that has been done without giving an opinion as to whether the rates have been affected in this or that locality.

In about 20 counties, local tuberculosis societies have been founded to carry on the work, leaving the state society free to work in the more sparsely settled counties which have not yet been able to support a county organization.

The work has been educational from the start and diagnostic clinics have been started soon after the foundation of the society. Many of these clinics have only been operated for the past 5 years, which is the chief reason why we cannot see any decrease in the county rates although the work may have been carried on quite effectively.

From 50 to 5,000 patients have been examined yearly in the several counties, the work being almost entirely local; that is, few non-

residents being cared for. The sanatoria and hospitals have also done excellent work. We have noted these previously because of their varying sphere of influence. The results of their work cannot be effectively recorded in any statistical way.

Besides the State Sanatorium and the American Legion Hospital, there are a total of 22 sanatoria under county, municipal and private ownership. The 4 state hospitals for the insane also have beds set aside for tuberculous patients, and at the Ionia Reformatory a tuberculosis hospital is maintained for criminals. The total number of beds available in the state is 2,432, while the deaths in 1926 numbered 3,041; or an average of 8 beds to every 10 deaths, which, although it is above the 7 to 10 ratio that Drolet found for the United States, and above the ratio for many foreign countries, is still below the estimated requirement of 1 bed for every death.

It is undoubtedly true that the modern facilities for the care of tuberculosis, which are perhaps best represented by the number of sanatoria beds, have an undoubted influence on the rate but it is probable that this cannot be directly traced. Michigan is fortunate in some ways in that it has been able to increase the facilities for the care of this disease.

The available beds for tuberculosis have increased from 75 in 1904 to 2434 in 1926. Tuberculosis sanatoria affect the tuberculosis morbidity and mortality in the following ways:

1. Arrests the disease and cures in incipient and moderately advanced cases
2. Isolate hopeless cases and thus prevent infection and contacts, particularly children in the family
3. Serve as educational centers for dissemination of knowledge regarding:
 - Prevention of infection
 - Early diagnosis
 - Cure of clinically ill tuberculosis
 - General hygiene
 - Education of physicians and nurses in the care of tuberculosis
 - Experimental studies and research

We believe that the subject as here presented can only cover the more important factors and that much would be gained by more extended research.

Present Requirements and Procedure for Washing Milk Bottles*

RALPH E. IRWIN, M.S., FELLOW A.P.H.A.

Chief, Milk Control Section,

Pennsylvania Department of Health, Harrisburg, Pa.

MILK BOTTLES are washed for two purposes—first, to remove organisms or chemicals that may injure the milk or the milk consumer; second, to secure a clean looking bottle.

Jones¹ states:

The cleanliness of the final package in which milk, cream, and manufactured products are marketed is an index to the consumer that signifies to no little degree the care taken in plant operation. Without clean and sterile apparatus a high quality product cannot be marketed, and it stands to reason that the bottles must be physically and bacteriologically clean as well. . . . When the actual cost of maintaining sanitary conditions throughout the plant is considered it is comparatively small considering its importance to successful operation.

The milk bottle is cleaned through the use of various washing compounds and sterilizing agents, either with or without heat, by hand or in power driven machines. The word "sterilization" in connection with the washing of milk bottles does not carry the meaning usually given this term by the laboratory technician. Among milk plant workers the word "sterilized" means "practical sterilization" or "commercial sterilization." This is indicated in the paper prepared by Jones¹ when he says:

There seems to be no set standard on bacteria count of milk bottles or a method for determining the same. The opinions of different plant operators and dairy authorities seem to vary more or less on this point. It is the writer's view that quart bottles should not contain more than 100 bacteria per bottle. In some plants a standard of 500 bacteria per quart bottle is considered as sterile.

Myers² says:

Sterile bottles, although desirable, are not essential. Clean bottles, free from pathogenic organisms and with a low content of non-pathogenic bacteria, are all that is necessary from the sanitary point of view. If the washing operation can be made so efficient that the bottles when rinsed are clean and free from all disease producing microorganisms, the expense and time required would be decreased to some extent.

In this paper an attempt is made to set forth the present state

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

requirements for cleaning milk bottles, and the conclusions reached by various investigators who have studied the problem.

State Requirements—Each state and the District of Columbia was asked to submit a copy of its regulations for cleansing milk bottles. The replies to this request may be grouped as follows:

- 14—No regulations for bottle washing.
- 6—Require bottles to be thoroughly cleansed.
- 2—Require bottles to be thoroughly cleansed and sterilized.
- 2—Require bottles to be washed and sterilized with steam.
- 8—Require bottles to be washed and sterilized with steam or hot water.
- 2—Require bottles to be washed and sterilized with steam or chlorine solution.
- 14—Require bottles to be rinsed, cleaned with an alkali solution and sterilized with steam or some other method approved by the state health authority.
- 1—Requires bottles to be washed and treated with hot water or steam or 5 per cent caustic soda solution or concentrated lye.

From the state requirements just given it is apparent that it was not intended to give specific directions for the cleansing of bottles. Fourteen states give certain general directions and then provide for other methods that the state health authority may indicate. Thus the health authority is left free to recognize any advancement in methods for cleansing bottles and approve the use of such methods. Only one state has specified the strength of washing solutions. It seems to be the opinion of the legislator that definite instructions should not be given at this time.

Conclusions of various investigators—In the studies reviewed three general types of bottle washers are considered:

1. *Hand Operated Bottle Washer*—This consists in first submerging the bottles in water containing a washing powder, then placing them on a revolving brush and finally applying steam through a perforated plate with manually operated valve or submerging the bottles in a tank containing a chlorine solution.
2. *The Hydraulic Washer*—This is a power driven machine in which a hot washing solution is pumped through jets into the bottles, then rinsed with clean water and finally treated with hot water or steam.
3. *Soaker Type Washer*—This is a power driven machine in which the bottles are attached to an endless belt which carries them through solution tanks in which the bottles fill and empty, then pass jets which spray washing solutions inside and outside or they are brushed inside and outside and finally cooled by cold water sprays for delivery to the conveyor connected to the bottle washer.

The chemicals used in the study made by the investigators include:

Sodium carbonate	Soap or colloidal alkalies
Sodium bi-carbonate	Tri-sodium phosphate
Sodium hydroxide	Chlorine

When bottles are hand washed the soda compounds act simply as cleansing agents and are not considered of sufficient strength to have a germicidal action. In machine washers, the strength of the solution

is not limited and the use of the chemicals as both cleansers and sterilizers has been studied. Sommer³ states:

The problem in washing bottles is to remove dried and curdled milk solids. A limited number of bottles will contain other foreign matter of a varied nature. To find a substance which would remove some of this foreign matter would be tantamount to finding a universal solvent. This would not be economical even if it were possible. . . . sodium hydroxide on account of its alkalinity is the logical choice as the cleansing chemical, its successful use without any additional chemicals verifies this choice, tri-sodium phosphate is necessary in the rinse in order to obtain a clear bottle, especially in the case of hard water.

Myers² concludes that:

Lowering the pH of a washing solution by the addition of acid and by dilution has been shown to decrease its germicidal efficiency. Likewise, raising the pH of a washing solution by the addition of sodium hydroxide has been shown to increase its germicidal efficiency. Spores, although not destroyed readily by even extremely high hydroxyl ion concentration, have been shown to be destroyed in 5 minutes by the combination of a pH of 12.0 and a temperature of 80° C.

Myers' study⁴ of the action of washing solutions on the tubercle bacillus causes him to conclude:

. . . from what is known of the resistance of the tubercle bacillus to chemical disinfectants, especially alkalies, that the only effective means of destroying this organism in a short time is by heat. . . . It seems advisable to maintain constantly in the washing solution a pH near 13.0 and a temperature of at least 60° C. (140°F.) where the bottles are permitted to soak for 15 to 20 minutes in the washing solution. These conditions will insure clean, safe bottles, providing the rinse water is safe.

Myers² has studied the effect of alkalinity in the destruction of bacteria and concludes:

The higher the temperature and the higher the hydroxyl ion concentration the shorter is the time necessary for the destruction of a given number of organisms. *Bacterium coli* is readily destroyed in cold solution when the hydroxyl ion concentration is as high as pH 11.0.

Parker and Smith⁵ through both laboratory and field work have made a study of the detergent and germicidal efficiency of a colloidal-alkali mixture. These investigators state:

There are two classes of dirt which detergents have to remove; one, where the particles of dirt are held to the substance to be cleaned by means of grease or oil; the other, where the dirt is held to the substance by the adsorption of the dirt to the surface of the substance. In the first case, by emulsifying the grease or oil, the binder between the dirt and the substance is broken and the dirt rinses away freely. In the other case, the adsorption between the colloidal material and the dirt is greater than the adsorption between the dirt and the substance being cleaned and, as a result, the particles of dirt are surrounded by a film of the adsorbed colloidal material and the dirt is then easily rinsed away.

It is shown that a soap solution belongs to the class of solutions known as colloidal solutions and since soap is a detergent it is classified with other detergents such as caustic alkalies and alkali carbonates.

The use of soap in conjunction with alkalis is explained as follows:

The fact that the detergent value of soap is due to its physical properties as determined by its colloidal nature, and also, that while the soda and caustic compounds ordinarily used for detergent purposes are of definite germicidal value, they lack the inherent cleansing properties of soap—led to the development of colloidal alkalis. Thus, the colloidal alkali possesses in addition to the effective alkalinity of the caustic and soda compounds, the detergent properties of ordinary soap.

From their field and laboratory studies these investigators conclude:

Apparently, the chief merit of a colloidal alkali lies in the improved detergency whereby the activity of its causticity is enhanced through the mechanical or physical removal (or perhaps, exposure) of bacteria from the dirt binder (in which they are entrapped) by emulsification of the grease and fats or by the adsorption between the dirt and the colloid. . . . The best results both from physical and bacteriological points of view were obtained by using the colloidal alkali mixture with actual caustic strengths of 1.2 per cent and 1.6 per cent NaOH and temperatures of 120° and 160° F. When using caustic soda alone as a detergent, the best results were obtained with concentrations of 4.0 per cent and 4.5 per cent NaOH and temperatures of 120° and 160° F.

Parker* in a very recent paper concludes:

The newer knowledge concerning alkali detergents used in the automatic cleaning of glass containers may be summed up by stating that the germicidal properties of alkali detergents is determined by their causticity while their detergency can be enhanced through the development of compounds possessing in addition to the inherent degree of alkalinity, a colloidal nature. By utilizing this knowledge, detergents can be developed that will provide the maximum cleansing and germicidal properties.

Drain* carried on a rather extensive laboratory study of the efficiency of hypochlorites and chlorinamines in the sterilization of milk bottles. In addition to a solution of chlorinated lime, made in the laboratory, commercial products were used such as B-K, Germ X, hypozone and sterilac. The commercial preparations were used according to the recommendations of the manufacturers. *Streptococcus lacticus* grown in lactose broth or secured from milk cultures was selected for the test organism. In a part of the study, commercial conditions were approximated by the use of a Blue Line Junior bottle washer which had a capacity of 2 cases per minute. A number of tests were made and hundreds of bottles were used. The investigator concludes:

Thorough rinsing mechanically removes large numbers of bacteria from milk bottles. Chloride of lime solution is very unstable and is effective only when fresh. The hypo chlorite weakens rapidly in a hot solution. Any organic matter accidentally carried over on the bottles or cases weakens it. The addition of steam to the rinse tank to keep a uniform temperature dilutes it. The chloramine solution did not reach its maximum efficiency for one or two days after being made up. Some commercial solutions contain a killing strength longer than others.

Whittaker, Archibald and Shere* studied the efficiency of bottle

washing equipment in a large number of milk plants operating in the State of Minnesota. Among these plants there were installations of hand operated bottle washers and hydraulic bottle washers. In some cases steam was used as the final cleansing agent, in others steam and hot water were sprayed into the bottles through a series of perforated plates. In the plants using chlorine, the chlorine was applied by submerging the bottles in a rinse tank or it was added to the rinse and sprayed into the bottles through perforated plates. The investigators conclude:

The results obtained on the sterilization of bottles with apparatus using steam as compared with chlorine solutions indicates that chlorine is more dependable as applied in routine practice at the plants investigated. This is especially evident at the smaller pasteurization plants where manually operated apparatus is used. Steam, when properly applied with the automatic machines, gave satisfactory results, but it was observed in many instances the operators neglected to carry out certain details that are necessary in order to accomplish effective sterilization. . . . no cases have been reported of objections having been made to odors or flavors being imparted to the milk, or of any misuse of the chemical.

Whittaker and Archibald^o conducted a study to determine the strength of a chlorine solution that is suitable for the final cleansing of milk bottles. This resulted in recommending that "the rinse water contain not less than 35 parts per million of available chlorine." It was further shown that the rinse water should be tested from time to time to insure effective sterilization.

Some of the investigators quoted, have indicated that the usual strength of the alkali solution used in bottle washers is not sufficient to kill the tubercle bacillus and that sufficient heat should be applied in order to accomplish the destruction of this organism.

Calmette["] indicates the resistance of the tubercle bacillus to chlorine and caustic soda when he recommends the isolation of this organism by the use of antiformin. The procedure is given in part as follows: A measured quantity of the pathological material containing tubercle bacilli

. . . is mixed in a sterile centrifuge tube with an equal quantity of a 30 per cent solution of antiformin. The tube is corked with rubber, shaken vigorously and allowed to stand for one hour; then, after centrifugation, the supernatant fluid is poured off . . . The antiformin destroys almost all the contaminating bacteria and one usually succeeds in this way in obtaining pure cultures from the start.

It appears then that both alkali and chlorine used in milk bottle washing may not be relied upon to destroy this organism and that heat should be used.

Park["] has studied the thermal death point of tubercle bacilli for different periods of time at temperatures which might be employed for the pasteurization of milk. These results indicate the time and temper-

ature that may be necessary for the efficient operation of milk bottle washers. The table given by Park is as follows:

THE THERMAL DEATH POINT IN MILK OF THE TUBERCLE BACILLI EXPOSED
FROM 1 TO 30 MINUTES

155°	1 minute
145°	6 minutes
142°	10 minutes
140°	15 minutes
138°	20 minutes
136°	30 minutes

Possibly it is not necessary to use a bottle washing process that will kill tubercle bacilli. This subject should receive attention.

DISCUSSION

It is believed that the laboratory results reviewed set forth sufficient facts to warrant an extended study of their application in the field. More work similar to that carried on by Whittaker, Archibald and Shere is needed. A field laboratory equipped for chemical and bacteriological work in milk treatment plants and in charge of a technician acquainted with the practical operation of the equipment to be studied would no doubt answer many of our questions. The manufacturers of bottle washing equipment have made rapid advancement in the last 5 years. It may be that our knowledge of washing compounds and their application has not kept pace.

There is opposition to the use of steam or the use of hot water above 160° or 170° F. Possibly there are chemical combinations that will make high temperatures unnecessary. If this is shown to be true then the health authorities should give their sanction and the legislator should make the use of such methods possible and necessary.

Brucella Abortus in Milk and Dairy Products*

C. M. CARPENTER, Ph.D. and RUTH BOAK, M.S.

*Diagnostic Laboratory, New York State Veterinary College, Cornell University,
Ithaca, N. Y.*

MEDICAL literature continually records a slow but steady increase in the number of cases of undulant fever in the United States. Since Keefer's report of the first case in 1924,¹ the authors have examined either cultures or blood serum, and sometimes both, from 24 patients suffering from this disease and know of 45 more cases which either have been reported in the current medical journals or have been called to their attention by personal communications with other bacteriologists interested in this disease. Undoubtedly, this is only a small percentage of the actual number that is occurring. We believe that there is no more of this disease in man at present than there has been for many years, but the finding of *Brucella abortus* infection in man explains some of the hitherto unidentified fevers which may have been ascribed to other bacterial agents.

The source of the infection in man demands the most careful study. There are two probable methods by which man may be infected, one wound infection and the other the introduction of the organism into the alimentary tract. Although the former should not be overlooked, the latter appeals to us as a more logical manner for the infection to occur. Therefore, we believe that it is necessary to examine those foods in which *Brucella abortus* naturally occurs. That milk contains *Brucella abortus* has been known since Smith and Fabyan² and Schroeder and Cotton³ described the infection in guinea pigs that had been injected with milk containing this organism. Their findings have been verified by many other observers and following such findings, some work was done to determine whether the presence of this infection in milk had any deleterious effect upon the health of man. Only meagre evidence was obtained at that time to show that any danger existed from drinking raw milk containing this organism. Because of the presence of this organism in the milk from certain cows that harbor *Brucella abortus* in their udders after abortion, and because of the recognition of the disease in man, these studies were undertaken.

* Read before the Laboratory Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

The amount of abortus infection eliminated in the milk from a cow harboring the organism in her udder is very variable, but for the most part the greatest numbers are present soon after abortion. The infection in certain animals will become greatly reduced or disappear in 3 or 4 weeks, while in others it may persist throughout a lifetime. Very few studies have been made concerning the numbers of the organism that are discharged in the milk by a carrier. Evans¹ examined milk from 2 cows that had been artificially infected many times with *Brucella abortus*. The largest number of abortion bacilli recorded by her was 145,000 per cc. of milk. Her studies showed that virulent strains of the organism were not eliminated continually in great numbers in milk from aborting cows. In our experience with naturally infected animals we have found only a comparatively small number present in milk. Plate counts of milk from carriers in several herds showed an average of from 20 to 440 per c.c. Because of the difficulty in growing *Brucella abortus*, due to its peculiar demand for an increased amount of CO₂, the number observed may be only a general index to the exact number of living organisms present in a sample. The work of Huddleson² and that carried on in our own laboratory have demonstrated quite conclusively that by far greater numbers of the organism occur in the cream rising from a sample of milk than in the sediment or whole milk. Cultural methods have been used, but in our experience the injection of guinea pigs with cream removed from a given sample of milk is a more satisfactory method of determining whether or not the organism is present.

When one examines the literature concerning the percentage of infected cows that eliminate *Brucella abortus* in their milk, or the amount of infection that is present in market milk, he is impressed with the great variation in the results obtained by the several investigators. Schroeder and Cotton³ observed the infection in 83.3 per cent of 30 cows showing specific abortus agglutinins in their serum diluted 1-100 or higher. The author⁴ observed *Brucella abortus* in the milk of 66.6 per cent of a group infected with the disease. Pfenninger⁵ found infection in 34.8 per cent of his cases, Sheather⁶ in 34 per cent and Fitch and Lubbehusen⁷ in 29.9 per cent. A study has just been completed upon the milk from 378 cows from 3 certified dairies under one management. Infection was observed in 6.08 per cent of these animals as determined by guinea pig injection. Approximately 20 per cent of the cows showed specific abortus agglutinins in their blood serum. Studies on the presence of the infection in market milk have not been so extensive. Evans⁸ observed it in the market milk of the city of Washington, while Fleischner and Meyer⁹ recovered it from certified

milk in San Francisco. Carpenter and Baker¹² found that 18 per cent of mixed milk samples from 50 herds supplying the city of Ithaca contained *Brucella abortus*. Undoubtedly, the dilution factor is responsible for the lower incidence of infection in market milk.

Because *Brucella abortus* occurred in milk and cream, we desired to determine its longevity in cream, butter and other milk products. Samples of naturally infected cream, as stated heretofore, show a large amount of infection because the fat globules carry up the organisms when they rise to the surface. Huddleson⁵ states that the infection does not appear to multiply in milk and cream held at ice box temperature. He observed that the number of viable organisms decreases rapidly when held longer than 8 days, and after 60 to 90 days he was unable to recover the infection from the milk. He does not state the hydrogen ion concentration of the milk at the time when he found the organism not viable.

To test the longevity of *Brucella abortus* in cream, one quart of pasteurized cream with a 40 per cent butter fat content was purchased from a local creamery. The quart of cream was divided into 4 equal amounts of approximately 250 c.c. each and placed in sterile Ehrlenmeyer flasks. Each flask was then inoculated with 5 c.c. of a water-clear suspension of *Brucella abortus* prepared in the following manner: The cultures were grown on a nutrient serum agar for 48 hours, then washed off with a sterile physiological salt solution and diluted to give a reading of 3 cm. on the Gates¹³ apparatus. One c.c. of this suspension was then added to 99 c.c. of a physiological salt solution which made the water-clear suspension. Four strains of *Brucella abortus* were used in the experiment and each flask of cream was inoculated with a different culture. Three of the strains, 80, 5532 and 5549 were isolated from milk, while the fourth, H-1, was recovered from the blood of a patient suffering from undulant fever. After thoroughly mixing the abortus suspensions with the cream, cotton stoppers were placed in the flasks and the cream was stored in the refrigerator at 8° C. Guinea pigs were then injected 4 times at 2-day intervals with 2 c.c. of each sample of infected cream to determine the length of time the culture of *Brucella abortus* would remain viable. After 8 days had elapsed guinea pigs were injected with the cream at 5-day intervals. The hydrogen ion concentration of the cream at the time of purchase, as determined by the colorimetric method, gave a pH of 6.

The longevity of *Brucella abortus* in butter was determined in a manner similar to that used with the cream. Four pounds of butter prepared from pasteurized cream were obtained and 10 c.c. of the same suspensions as used to inoculate the cream were mixed with each

pound of butter. The salt content of the butter was 1.5 per cent. The butter was then melted at incubator temperature and the culture agitated thoroughly with the fluid butter. The infected samples of butter were stored in the same manner as the cream, and guinea pigs were likewise injected.

The guinea pigs that received the samples of cream were autopsied at approximately 5 weeks after their injection and observations were made for lesions of abortus infection. The spleen was aseptically removed and placed in a sterile Petri dish for culturing, which was done by removing bits of the splenic tissue with sterile forceps and transplanting on serum agar. The cultures were either sealed with sealing wax or grown in jars in which 15 per cent of the atmosphere had been replaced with 10 per cent CO_2 . A sample of blood was removed from the guinea pig's heart and the serum set up with a known abortus antigen and tested for abortus agglutinins. The cultures from the spleens were allowed to incubate at 37°C . for 1 week and were then examined for evidence of growth of *Brucella abortus*. The cultures were identified upon their morphological characters, absence of motility, their inability to ferment a 1 per cent solution of dextrose in Hiss serum water and their agglutination by an anti-abortus serum. An agglutinin absorption test was completed on the culture if any doubt remained concerning its identity.

The results of such examinations showed that 2 of the strains, 80, isolated 7 years ago by K. F. Meyer" from certified milk and the human strain, H-1, recovered from a case of undulant fever remained viable in the cream and butter longer than the 2 other milk strains, 5532 and 5549, recently recovered by guinea pig injection. The cream infected with the 2 former cultures produced abortus infection in guinea pigs over a period of 10 days, while the latter failed to infect after 8 days. The inoculated cream failed to infect when the hydrogen ion concentration gave a reading of pH 5. Undoubtedly the death of the abortus organism was hastened by the production of lactic acid.

The samples of butter inoculated with strains H-1 and 80 produced abortus infection in guinea pigs for 142 days after inoculation, indicating that they were still viable at the end of that period. However these 2 strains caused no infection in guinea pigs 190 days after the butter was inoculated. Strain 5532 produced infection 81 days later, but not at 142 days. Strain 5549 failed to infect after a 32-day period.

Few examinations have been made upon market butter. Seventeen $\frac{1}{4}$ pound samples of butter were purchased from the local stores. This butter was brought to the laboratory and melted in the incubator. Two c.c. from each sample were injected subcutaneously into guinea pigs.

These guinea pigs were killed and autopsied at the end of 5 weeks as previously described. *Brucella abortus* was not demonstrated by animal inoculation to be present in the samples examined.

The causative agent of Malta fever was described by Bruce¹⁶ in 1891. Further studies by the Mediterranean Fever Commission¹⁷ showed conclusively that the infection is prevalent in goats' milk and that this is the chief source of infection in man in the Mediterranean district. In 1918 Evans¹⁸ observed that *Bacillus abortus* of Bang and *Micrococcus melitensis* described by Bruce possess practically identical biological characters and that the only reliable means of differentiating the 2 organisms is the agglutinin absorption test.

It has been suggested by some investigators that the source of infection of undulant fever in the United States may be due to the eating of imported cheeses. Many of the goats, sheep and cattle of the Mediterranean district and southern Europe are infected with *Brucella melitensis*. Since a quantity of sheep's and goats' milk is used in making these fine grades of imported cheeses consumed in the United States, a thorough examination of these cheeses for abortus and melitensis infection was made.

Due to the courtesy of the Kraft Cheese Co., the F. X. Baumert Cheese Co., Roethlisberger & Co. and the J. S. Hoffman Co. of New York City, we were able to obtain many samples of imported cheeses. Several samples of cheese were collected from the local market also. The samples collected locally were in the original packages and jars. The samples of cheeses examined from the above importing houses were collected with a standard cheese tryer in the form of small cylinders about $\frac{1}{2}$ inch in diameter and 3 inches long. The samples were then put into sterile tubes, labeled and brought to the laboratory.

The cheese was prepared for injection into guinea pigs in the following manner: First, the external surface of the cylinder was seared with a hot spatula to prevent the possible contamination of one sample by another because of using the same tryer in collecting all the samples. A piece of the sample about $\frac{3}{4}$ inch long was then cut off with a sterile knife or a similar amount taken from a jar or package and ground in a mortar with 2 c.c. of a physiological salt solution. Two c.c. of this mixture was then injected subcutaneously into a guinea pig.

Several of the injected guinea pigs died in a few days. They were autopsied and other pigs injected from the same samples of cheese with the exception of 2 cases in which the guinea pigs were found to be infected with *Vibrio septique* which was evidently in the cheese. Because of this infection it was decided that reinjection was useless.

Of the 82 samples of cheese collected, 72 were imported. Of this

number 30 were manufactured in Italy, 14 in France, 13 in Switzerland, 6 in Holland, the remainder in England, Germany, North and South America. The majority of the types examined were Swiss, Roquefort, Reggiano, Gorgonzola and Edam cheeses. Infection with *Brucella abortus* or *Brucella melitensis* was not found in any of the guinea pigs injected with these samples.

DISCUSSION

The percentage of cows from the certified dairies harboring *Brucella abortus* in their udders was 6.08. Guinea pigs were injected with 2 c.c. of a mixed sample of cream from either 4 or 5 cows. If abortus infection was observed at autopsy guinea pigs were then injected with individual samples from the cows comprising the group. Due to this method of carrying out the work, milk from 18 cows could not be reexamined because their lactation period had ended. Therefore, the correct percentage of infection should be slightly higher. The number of carriers, however, was much smaller than we expected to find, inasmuch as approximately 20 per cent of the cows showed specific abortus agglutinins in their blood serum.

We believe that the injection of guinea pigs with the cream from the samples is as accurate as any method for determining the presence of *Brucella abortus* infection in milk. Although it is not yet known how few abortion bacilli are required to infect a guinea pig, evidence points to the fact that only a few are required. The work of Hagan²² shows that 100 or fewer abortus organisms will infect guinea pigs weighing from 385 to 495 grams. Perhaps an explanation for so little abortus infection in such a large group of cows from certified dairies is due to the fact that an animal is eliminated from the dairy if she is a poor producer and often aborting cows have short lactation periods and secrete a small amount of milk. Therefore many such infected animals would be removed. The strict sanitation practiced in a certified dairy may help reduce the number of carriers if abortus is spread from one animal to another through the invasion of the teat canal. The abortus lesions produced in the guinea pig were typical of bovine strains. No distinct abscessation of the lymph glands, spleen or liver, such as often develop in guinea pigs injected with human and porcine strains, was observed. The joints were not affected and the majority of the guinea pigs showed an increase in weight.

There is a possibility that many of the abortus organisms may have been destroyed by the bactericidal effect of the milk or by being chilled by the ice during the shipment from the dairies to the laboratory, which was in some instances practically 72 hours after the samples were collected. With such a small amount of infection in such a large

quantity of milk, the dilution factor would be so great it would undoubtedly be difficult to recover the organisms from the mixed milk, although *Brucella abortus* may occur in large numbers in milk from a certain animal. However, our studies show that comparatively few are present. The number discharged daily in the milk is very variable. The results of the Mediterranean Fever Commission²⁶ on the number of *Brucella melitensis* organisms present in goats' milk each day showed a variation from none to 30,000.

If man becomes infected from certain strains of *Brucella abortus* that may be in milk, cream would be a greater infective agent than whole milk, because the largest number of the organisms occur in the cream. We fail to find the results of any observation on the length of time the organism can live in cream, but from the work we have done, it seems evident the percentage of butter fat in the cream and the hydrogen ion concentration of the skim milk in the cream are the controlling factors. It will be noted that of the 4 strains used, two, 80 and H-1, remained viable 2 days longer than two recently isolated, strains 5532 and 5549, which were recovered from milk. Strain 80 was isolated from milk about 7 years ago and in our studies has always been more virulent for guinea pigs than the other 2 milk strains. The human strain used also produced extensive abortus lesions in guinea pigs. The artificially inoculated cream failed to infect guinea pigs when the pH became 5. Evidently the higher the percentage of butter fat, the longer *Brucella abortus* will live in a given sample of cream if stored at refrigerator temperature because the more compactly the fat globules are packed, the less skim milk can the sample contain. The work of Sharp and McInerney²⁷ shows that the hydrogen ion concentration of a sample of cream or butter is approximately the same as that of the skim milk or buttermilk in it. This evidently indicates that butter made from sweet cream infected with *Brucella abortus* will still contain living abortus organisms, and that if butter made from sour cream does not reach a pH of 5, the infection may be carried over in this butter also. The above hypothesis becomes strengthened when it is considered that the same strains of *Brucella abortus* as used in the cream remained viable in butter for about 15 times as long as it did in cream. The amount of infection in the butter was approximately the same as that in the cream. We do not consider that the samples were any more heavily infected than would have occurred under natural conditions.

Two of the cultures, 5532 and 5549, inoculated in butter, infected guinea pigs 81 days and 32 days respectively after the butter was inoculated and stored in a refrigerator, while no infection was found in guinea pigs injected after 142 days and 41 days respectively. Strain

H-1 and 80 still produced abortus in guinea pigs at the end of the 142-day period, showing that the butter had no marked bactericidal effect on the culture. The hydrogen ion concentration of the butter had changed only very slightly during this period. It is interesting to note that the 2 strains H-1 and 80, most virulent for guinea pigs, were the most resistant in the cream and butter.

The examination of 17 samples of market creamery butter for *Brucella abortus* showed no viable organisms, but, undoubtedly, most of the samples and perhaps all were made from pasteurized cream. It is difficult to draw any conclusions concerning the infection in market butter from such a small number of samples, and especially so inasmuch as the manner in which the butter was made is not known.

No evidence of *Brucella abortus* or *Brucella melitensis* was found from the injection of guinea pigs with extracts of cheeses. Since imported cheese was suggested as a possible source of infection for the cases of undulant fever occurring in the United States, we thought it important to make these examinations. However, the methods employed in manufacturing and processing these cheeses, such as heating, souring and ripening, militate against the chance of these organisms being viable in cheeses, even though they may have been present in the various types of milk and cream from which they were made. The Mediterranean Fever Commission¹ studied the length of time *Brucella melitensis* would live in cheese and particularly in the type of cheese which is similar to the so-called "cottage" cheese that is made in the United States. It is prepared from whole goats' milk to which acid or rennet is added to curdle the milk. The curd is then put in basketwork moulds so that the whey may drain off. The acidity of this cheese varied from +80 to +90 when titrated with N/5 KOH, phenolphthalein being used as an indicator. The organism was never found viable in such cheese 48 hours after its preparation.

An examination of 82 samples of various types of cheese may not be sufficient data upon which to base conclusions concerning the general situation but we believe that the information obtained indicates that *Brucella abortus* and *Brucella melitensis* are rare in cheese if not entirely absent.

Not many data are available on the thermal death point of *Brucella abortus*, but the evidence at hand from preliminary studies indicates that proper pasteurization, such as recommended for the destruction of the tubercle bacillus in milk, 140°F.-145°F. for 30 minutes, will destroy *Brucella abortus*. We have completed thermal death point studies on the four strains of *Brucella abortus* used in the foregoing experiments to inoculate the cream and butter artificially and we

found a variation in the thermal death point of the 4 cultures employed. The 2 strains, 80 and H-1, most virulent for the guinea pigs, remained viable after exposure for 10 minutes at 140° F., while the other 2 less virulent strains, 5532 and 5549, failed to grow in cultures after 10 minutes' exposure at the same temperature. The 2 former strains were dead, however, after 15 minutes exposure at 140° F. At 160° F. all 4 strains were living after exposure for 30 seconds but dead after exposure for 1 minute.

CONCLUSIONS

1. The cream from samples of milk from 378 cows injected into guinea pigs showed that 23 cows, or 6.08 per cent were eliminating *Brucella abortus* in their milk.

2. Two bovine strains of *Brucella abortus*, 5532 and 5549, artificially inoculated into cream and stored at 8° C., remained viable for 8 days. Two other strains, 1 bovine, 80, and 1 human, H-1, more pathogenic for guinea pigs than the above strains, infected guinea pigs for a period of 10 days after being inoculated into cream.

3. The 2 strains 5532 and 5549 of *Brucella abortus* artificially inoculated into butter and stored at 8° C. remained viable and infected guinea pigs for periods of 81 and 32 days respectively. The other bovine strain, 80, and the culture H-1, isolated from the blood of man, were viable at 142 days after being inoculated into the butter, but not after 192 days.

4. Guinea pigs injected with 17 samples of market creamery butter showed no evidence of *Brucella abortus* infection at necropsy.

5. Guinea pigs injected with 82 samples of cheeses, mostly imported varieties, failed to show any evidence of *Brucella abortus* or *Brucella melitensis* infection.

Typhoid Fever in Knoxville, Tenn.

With Special Reference to Findings in a Sanitary Census Conducted Through the Schools

E. GARRIDO MORALES, M. D.; JAMES A. DOULL, M. D.
*School of Hygiene and Public Health, the Johns Hopkins University,
Baltimore, Md.*

and

MARVIN F. HAYGOOD, M. D.
Department of Public Welfare, Knoxville, Tenn.

WHEN the Bureau of Health of the City of Knoxville was reorganized in 1924, one of the first problems to receive attention was the institution of more effective control of typhoid fever. To this end a study of the prevalence and distribution of this disease was begun early in 1924; and in the following year the coöperation of the Department of Epidemiology of the Johns Hopkins University School of Hygiene was obtained.

The study, which will be very briefly outlined in this paper, has included:

1. A review of the history of typhoid fever in Knoxville during the past 20 years, comparing its course with that in other southern cities. This study has necessarily been based on mortality statistics, since reliable statistics of morbidity for the entire period are not available for Knoxville or for all the other cities.

2. A sanitary survey and census of the city with special reference to the existence and the local distribution of conditions presumably contributing to the prevalence of typhoid fever. This survey is not yet completed, and for purposes of this paper reference can be made only to some rather general facts and to data collected in a special survey in January, 1926.

3. A detailed epidemiological investigation of all cases of typhoid fever as reported in the city. As a necessary preliminary to this investigation vigorous efforts have been made to secure full and prompt morbidity reports from practicing physicians with a degree of success which has been gratifying.

The history of typhoid fever in Knoxville has been similar to that in most American cities in that the trend of mortality during the past 20 years has been consistently downward. Thus, in successive 5-year periods from 1906 to 1925, inclusive, the average annual mortality rates have been:

1906-1910	54.8 per 100,000 population	1916-1920	23.2 per 100,000 population
1911-1915	33.8 " " "	1921-1925	20.2 " " "

Notwithstanding the consistent decline shown by these figures the record to 1925 cannot be considered satisfactory because the rate of decline has been somewhat less in Knoxville than in most other southern cities for which records are available, and because, in the 5-year period 1921-1925, and in nearly every single year of that period, the mortality rate in Knoxville was higher than in most cities which are properly comparable as regards size and geographic location.

With respect to racial and seasonal distribution the statistics of Knoxville show what is usually found, namely, that the mortality has been consistently higher in negroes than in whites and that the season of greatest mortality has been from July to October, inclusive.

GENERAL STATUS OF PUBLIC SANITATION

The excessive prevalence of typhoid fever in cities has usually been found to be intimately related either to contamination of the drinking water, or to insanitary methods for the disposal of human excreta, or both. Therefore, while the study which is being made in Knoxville takes full cognizance of other factors, notably the milk supply* and the adequacy of bedside prophylaxis, the present account refers chiefly to the relation of the disease to water supply and excreta disposal.

Water Supply—The public water supply of Knoxville is now and for a number of years has been taken from the Tennessee River, from an intake located above the sewer outlets of the city. It is artificially purified by rapid sand filtration and chlorination, and is generally distributed throughout the city, so that it is accessible to practically the entire population.

The raw water at the intake is undoubtedly polluted to such extent that without purification it would be grossly dangerous for drinking purposes. The pollution is, however, chiefly from rather small and distant cities and from the surface-drainage of rural areas, and is not sufficient to impose an excessive burden upon a well constructed and well operated purification plant. The municipal purification plant, as it stood in 1925, was not ideal in all its features, but it was operated under expert supervision, controlled by necessary chemical tests, and the results checked by detailed bacteriological examinations made at the filter plant and independently in the laboratory of the Bureau of Health. These examinations indicate that the effluent was of con-

* In 1925, 21 cases of typhoid fever occurred in two distinct outbreaks attributed to contamination of milk from two dairies, carriers being responsible in both instances. Since then, there has been no concrete evidence of the transmission of typhoid fever in the city by milk or milk-products. In 1925 about 25 per cent of the city's milk supply was pasteurized. This proportion has now been increased to 50 per cent, and other improvements have been made in sanitary control.

sistently good quality as judged by the rather rigid bacteriological standards which are at present in vogue.

In previous years, from say, 1906 to 1920, the plant was less complete, lacking provision for chlorination, and was less skillfully operated; but in the opinion of U. S. Public Health Service officers who made careful surveys in 1911 and 1915 the water supply was at those times of a sanitary quality which compared favorably with that of most municipal supplies. These findings together with certain readily established facts concerning the local distribution of typhoid fever in Knoxville seem to us to indicate that the public water supply is not and in recent years has not been a factor of any considerable importance in the prevalence of typhoid fever in the city.

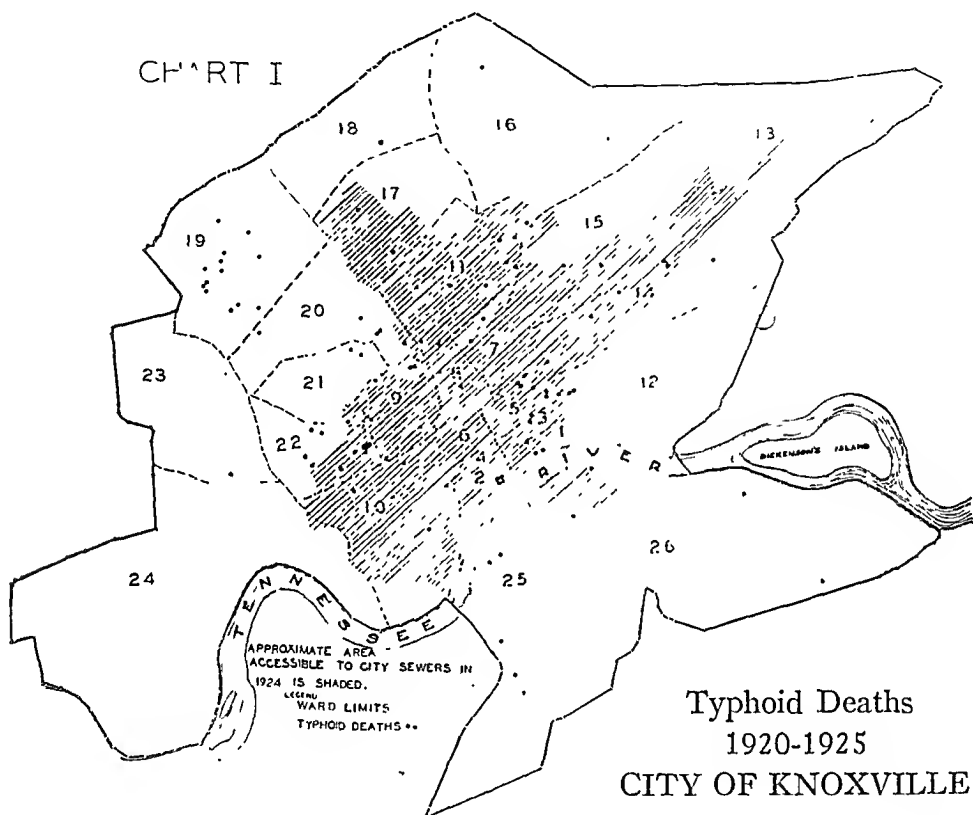

However, notwithstanding the fact that the public water supply is of good quality and is accessible to practically the entire population of the city, a certain proportion of the residents continue to obtain their drinking water from springs and wells. Many of these are so located as to be obviously subject to dangerous contamination with human excreta, and this opinion is confirmed by bacteriological evidence. For instance, in 1926 bacteriological examinations were made of 39 springs located within the city limits, and used by considerable numbers of people, each spring being examined twice. In 30 of the 39, the presence of *B. coli* was demonstrated in 1 c.c. or less of the water.

Prior to the study which is reported in this paper no exact information was available as to the number of persons habitually drinking water from springs and wells; but the results of the special survey which is cited later indicate that in 1925 probably from 5 to 15 per cent of the population was using water from such sources either habitually or occasionally.

Sewerage—In the report on the Municipal Health Department Practice for the year 1923, issued by the U. S. Public Health Service as *Public Health Bulletin, No. 164*, it is stated that in Knoxville, at that time, only about 50 per cent of the population was served by the public sewerage system and it was shown that with respect to completeness of sewerage, Knoxville stood very near the bottom of the list of the 100 cities included in the survey. It appears from information subsequently collected that this estimate of sewered population was too low, and that 60 per cent would be a closer figure for the year 1925.

The accompanying map, Chart I, shows the approximate area covered by the public sewerage system in 1924 and the geographical distribution of the deaths from typhoid fever for the 6 years, 1920-1925, inclusive. No definite relationship of typhoid to lack of sewerage is discernible. However, the map does not show the distribution of

insanitary methods of excreta disposal, since insanitary privies were fairly common in some of the sewered areas, while in certain of the unsewered areas provision was made in many houses for sanitary disposal of excreta by flush closets connected with cesspools, septic tanks or private sewers.

While it was not difficult, in 1925, to make a fair estimate of the aggregate sewered and unsewered populations, no exact information was available regarding the extent of the use of various methods of disposal. It was found impossible to complete the house to house survey during that year, and though the work is progressing it has not yet been completed. Therefore, in order to provide the information necessary for a study of the relation of typhoid fever to excreta disposal it was necessary to resort to the less exact but more expeditious method of securing information through the children attending public schools.

THE SCHOOL SANITARY CENSUS

By arrangement with the school board an inquiry of this kind was organized in January, 1926. A blank form asking the source of drinking water, location of toilet, number in family, etc., was drawn up and dis-

tributed, through the principals of the public schools, to the children of the 5th, 6th, and 7th grades in every public school in the city. Necessary explanations were given and each child was requested to fill out the record for his own home.

In this way information was obtained, in a single day, from 4,271 children, representing over 4,000 separate families, comprising about 25.6 per cent of the city's population in all sections of the city.

The accuracy of the information furnished was checked by sanitary inspectors of the Health Department, who were sent to about 140 of the homes which had been included in the survey; and by comparison of the reports of children where two or more had rendered reports for the same address. The information furnished in the school survey was found to be substantially accurate.

The records of this survey were first assembled and tabulated by wards, to show for each ward the proportion of the canvassed families using each of the designated methods of excreta disposal and the proportion habitually using water from springs or wells. In each ward separate tabulations were made for the white and colored populations. Considering the character of the population included in the school survey, it seems fair to assume that if the canvass had included the entire population, the distribution of sanitary conditions in each ward would have been approximately that indicated by the sample which was actually canvassed. On this assumption an estimate has been made, for each ward, of the proportion of the population falling into each class, and the estimates for individual wards have then been summarized into an estimate for the whole city. This summarized estimate is given in Table I.

TABLE I
ESTIMATED NUMBER OF PERSONS,* WHITE AND COLORED, USING DESIGNATED METHOD OF DISPOSAL

Method of Excreta Disposal	Number		Per Cent of Total			
	White	Colored	Total	White	Colored	Total
W. C. in house	45,080	4,511	49,591	55.3	32.5	52.0
W. C. in porch	11,052	3,117	14,169	13.5	22.5	14.8
W. C. in yard	3,165	1,718	4,883	3.9	12.4	5.1
Total Flush Closets**	59,297	9,346	68,643	72.7	67.4	71.9
Privies	22,305	4,515	26,820	27.3	32.6	28.1
Total	81,602	13,861	95,463	100.0	100.0	100.0

* Estimated population as of July 1, 1923

** Includes estimate of 1224 persons (1050 white and 174 colored) living in premises with both flush closet and privy

If it be estimated that about 5 persons use each privy or closet the above figures would indicate that at the time of this survey there were in the city about 5,360 privies, of which some 400 to 450 were located in the eight wards which were completely accessible to the public sew-

erage system. On the other hand, in the wards which are not reached by public sewerage system, considerable numbers of flush closets are reported, discharging into cesspools, septic tanks or private sewers.

The population of the city may be classified into those who habitually use city water for drinking and those who habitually use water from other sources, chiefly springs and wells. As there appears to be no great difference between the white and colored population with regard to the use of springs and wells, it seems unnecessary, in summarizing the data, to make a distinction between the two races. An estimate for the entire population of the city, is given in Table II.

TABLE II

ESTIMATED NUMBER OF PERSONS HABITUALLY USING DRINKING WATER FROM
(A) MUNICIPAL SUPPLY, AND (B) OTHER SOURCES

Source of Water Habitually Used in the Home	Population using designated source Number	Percentage
(a) Municipal Supply	89,408	93.7
(b) Other sources, chiefly springs and wells*	6,054	6.3
Total	95,462	100.0

* In making this estimate the few families reported in the school survey as using water both from the city supply and from springs and wells have been counted as using springs and wells.

Allowing, in each family, at least one child in school and one adult employed outside the home, it may be inferred that not less than 40 per cent of those who habitually drink spring or well water at home are in the habit of drinking the city water at school or at their places of employment, so that probably not less than about 96 per cent of the city's population (93.7 per cent plus 40 per cent of 6.3 per cent) drink the city water to some extent. There are some who habitually drink city water, who occasionally drink spring or well water, but it is probable that the great majority of the city's population, perhaps 85 or 90 per cent of the residents, rarely if ever drink water from any source except the public supply.

EXCRETA DISPOSAL AND SOURCES OF DRINKING WATER

Excluding cases of typhoid in persons residing outside of Knoxville, brought into the city for treatment, and excluding also cases in which the diagnosis of typhoid fever was withdrawn, there are included in the records of the Health Department, 249 cases of typhoid fever for the period May 1 to December 1, 1924,* 163 cases for the year 1925, and 57 cases for the year 1926. Each of these cases was visited by an agent of the department and the usual epidemiological data secured, including information as to the method of excreta disposal used in the home and the sources of drinking water used by the patient during the

* There were no cases reported during the first 4 months of 1924. If any cases occurred the number is probably small, so that the cases recorded may be assumed to represent the total for the year.

30 days prior to onset of illness. Of the 469 cases there are 29 in which the method of excreta disposal is not stated and 27 in which the sources of drinking water were not ascertained.

For the population of the city as a whole and for white and colored persons separately, the estimated attack rates for those living in homes provided with flush closets and with privies respectively, for the whole period May 1, 1924, to December 31, 1926, are given in Table III.

TABLE III
INCIDENCE OF TYPHOID FEVER, KNOXVILLE, TENN., 1924-26, INCLUSIVE; THE POPULATION CLASSIFIED BY COLOR, ACCORDING TO METHOD OF EXCRETA DISPOSAL

Method of Excreta Disposal	Estimated population using designated method			Typhoid Fever, 1924-26 (incl.)			Incidence per 10,000		
	W.	C.	Total	W.	C.	Total	W.	C.	Total
(a) Privies	22,305	4,515	26,820	151	70	221	67.7	155.0	82.4
(b) Flush Closets	59,297	9,346	68,643	189	30	219	31.9	32.1	31.9

* Exclusive of 29 cases in which the method of disposal is not stated.

According to this analysis, the population living in homes provided only with privies, suffered from typhoid fever more than twice as severely as did the population using flush closets in their homes. The difference is not to be explained by the larger proportion of negroes in the former class, for, as shown in the summary, the difference remains when separate analyses are made for the white and colored populations.

In the investigation of cases in 1924 no distinction was made; in the case records, between flush closets located in the house and those located outside, on the porch or in the yard; but in the 1925 and 1926 records this distinction was made. The populations using these different types of flush closets are given in Table I; and, combining these data with the records of typhoid fever cases reported in 1925 and 1926 the summary shown in Table IV may be made.

TABLE IV
INCIDENCE OF TYPHOID FEVER, KNOXVILLE, TENN.; (A) AMONG THOSE HAVING PRIVIES AND AMONG THOSE HAVING FLUSH CLOSETS, (B) OUTSIDE AND (C) INSIDE THE HOUSE.

Method of Excreta Disposal	Population	Reported cases of typhoid fever	
		1925 and 1926	Incidence per 10,000
(a) Privy:	26,820	Number	
(b) Flush closet outside on porch or in yard:		92	34.3
(c) Flush closet in the house:	19,052	41	21.5
	49,591	59	11.9

NOTE: Twenty-eight cases in which the method of excreta disposal was not stated have been omitted. This omission necessarily reduces the incidence rates in the last column, but presumably does not alter their ratios to each other.

The lowest prevalence of typhoid fever has therefore been in families living in houses with closets indoors; a considerably higher prevalence occurred in families using outdoor closets, which are often of less sanitary construction and less cleanly; while a still higher inci-

dence prevailed in the users of privies. While the three classes represented no doubt differ in habits and economic status, there can be little doubt that the differences which would have the most important bearing on typhoid morbidity are those in methods of excreta disposal.

When the data for individual wards are studied it is found that in general the higher the proportion of the population using privies, the higher has been the typhoid incidence in the period under consideration. This may be demonstrated by computing the coefficient of correlation, between the percentage of population using privies, and the typhoid morbidity rate, which is found to be quite high, ($.47 \pm .10$); or it may be shown more simply by grouping the wards as shown in Table V.

TABLE V

INCIDENCE OF TYPHOID FEVER, KNOXVILLE, TENN., 1924, 1925 AND 1926 IN THREE GROUPS OF CITY WARDS, CLASSIFIED ACCORDING TO PROPORTION OF POPULATION USING PRIVIES.

Classification of wards	Aggregate population July 1, 1925 (Estimated)	Per cent of group population using Privies		No. of cases* 1924, 1925 and 1926	Typhoid Fever Incidence per 10,000, 1924, 1925 and 1926
		Water from springs and wells			
Group I Wards with more than 50% of population using privies (wards 12, 13, 16, 19, 20, 21, 23, 24, 25, 26.)	26,376	71.2	15.6	183	69.4
Group II Wards with from 15 to 49% of population using privies (wards 1, 2, 5, 14, 18, 22.)	18,707	26.0	5.0	87	46.5
Group III Wards with less than 10% of population using privies (wards 3, 4, 6, 7, 8, 9, 10, 11, 15, 17.)	50,380	6.2	2.0	197	39.1

* Exclusive of 2 cases not allocated because of incomplete address

The parallelism between the proportion of privies and the prevalence of typhoid fever as shown in Table V is striking. The same is true when the data for individual years are examined, save that in 1924 there was a slightly higher rate (23.3) in Group III than in Group II (19.8).

Since negroes quite generally suffer higher attack rates than do white persons the question arises whether the high rate of Group I may not be due to an excess of negroes in the population. This, however, is not the case, as the proportions of negroes in the three groups is estimated to be as follows: Group I, 11.5 per cent; Group II, 17.4 per cent, and Group III, 15.0 per cent.

With regard to the possible influence of polluted drinking water from springs and wells in causing the difference between these groups, it will be seen that the percentage of population using spring and well water as estimated from the school survey is closely correlated with

the proportion of privies and with the prevalence of typhoid fever in the several groups; being highest (15.6 per cent) in Group I, lowest (2.0 per cent) in Group III, and intermediate (5.0 per cent) in Group II. Therefore, the evidence in this table might be interpreted as indicating that the prevalence of the typhoid fever is closely related both to the use of privies and to the use of spring and well water; and it is difficult to distinguish between the two influences.

Some light may, however, be thrown on the question by a further analysis of the data relating to Group I. In five of the wards comprising this group (Wards 13, 19, 24, 25 and 26), more than 20 per cent of the population is reported as habitually using water from springs and wells, while in the other five wards (Wards 12, 16, 20, 21 and 23) less than 15 per cent, usually less than 10 per cent of the population, use water from such sources. A comparison between two groups of wards may be made as follows:

	A.	B.
	Wards 13, 19, 24, 25 and 26, in each of which more than 50 per cent of the population use privies and more than 22 per cent use water from springs and wells.	Wards 12, 16, 20, 21 and 23, in each of which more than 50 per cent of the population use privies, but less than 15 per cent use water from springs and wells.
Aggregate Population 1925	12,325	14,051
Per cent using privies	70.9	72.4
Per cent using water from springs and wells	26.3	6.0
Cases of typhoid fever:		
1924, 1925 and 1926	119	64
Cases per 10,000 of population:		
1924, 1925 and 1926	96.5	45.5

Although the two groups of wards differ very little with respect to the proportions of their populations using privies, they differ rather widely as regards the use of water from springs and wells; and the prevalence of typhoid fever has been distinctly higher in the group where spring and well water has been most commonly used. This simple fact, taken by itself, is perhaps not very significant; but when taken in connection with the fact that many of the springs and wells are obviously exposed to dangerous pollution, it strengthens the conviction that the practice of drinking water from springs and wells located within the city has been a factor of real importance in keeping up the high prevalence of typhoid fever in the city.

A similar study of the prevalence of typhoid fever among those who drink city water and those who drink well or spring water, is complicated by the fact that the same person may drink water from different sources, so that the population cannot be accurately classified with respect to sources of drinking water. Thus, the records of the cases

investigated in 1924 and in 1925 show that the sources of water stated to have been drunk by the patients within 30 days prior to onset were as follows: municipal supply, in 275 cases; local springs or wells in 83 cases; both municipal supply and local springs or wells in 79 cases; and other sources, chiefly bottled water, in 5 cases.*

According to the estimate based upon the school survey the number of persons in the city who habitually drink water from wells and springs probably does not exceed 6,050, that is, about 6.3 per cent of the entire population, yet from the above summary it appears that 83 out of 442 cases of typhoid fever, or 18.8 per cent, have occurred in this small fraction of the population. Again, if it be estimated that the people who occasionally drink water from local wells or springs are three times as many as those who habitually use these sources, then the total number in this class would be about 24,200, or approximately 25 per cent of the city's population. But the cases of typhoid fever who had drunk spring water either habitually or occasionally number 162, which is 36.6 per cent of the total cases. It is evident, therefore, that the population which drank water from local springs and wells has contributed an unduly large share to the cases of typhoid fever which have occurred in the city.†

SUMMARY AND CONCLUSIONS

From every angle from which the question has been investigated in the foregoing analysis the fact stands out clearly that in Knoxville typhoid fever has been most prevalent among those who are living in most intimate association with privies and unsanitary outdoor flush closets, and among those who most commonly drink water from wells and springs.

The relative importance of infection through polluted water from such springs and wells, as compared with conveyance by other means from insanitary privies cannot be precisely ascertained without a much more detailed investigation. In practice, however, it is not necessary to make such a distinction, for these two means of conveyance are not truly separate and independent but are closely related, in fact, interdependent.

These being the observed facts the obvious remedies are the extension of the public sewerage system and the abolition of privies; the repair and replacement of insanitary outdoor flush closets, and measures to condemn unsafe springs and wells. It has not been possible

* In 27 cases, the source of supply was not ascertained.

† In 1924 a quite severe localized epidemic occurred, principally in the 19th ward. Investigation pointed strongly, if not conclusively, to spread of the infection by one or more public springs in the locality, widely used by the population.

to effect a wide extension of the sewerage system but additions are being steadily made and the regulations with respect to connections to the sewers are being enforced, 1964 being effected in the years 1925 and 1926. Active measures have been and are being taken with regard to insanitary privies, more than 5,000 being made "fly-proof" in 1925 and 1926. Also many of the springs and wells in use in 1925 have now been permanently closed and efforts are being made to abolish all within the city limits.

A well balanced judgment of the effect of these measures must await further experience in this city and statistics for comparison with other cities. To the present, however, the results are distinctly encouraging. In 1926, although the morbidity was low, there were 20 deaths* reported, the death rate being approximately the same as in 1925. In 1927, to September 17, there have been only 58 cases reported, exclusive of those brought to Knoxville for treatment, with 6 deaths.

* Of these 20 deaths, 4 were among non-residents, and 2 are included in the notified cases of 1925.

ACKNOWLEDGMENTS: The writers are deeply indebted to the School Board and to the various principals and teachers for their assistance in the school survey and to the various members of the Nursing, Bacteriological and Sanitary Divisions of the Bureau of Health for assistance involving much overtime work, in both laboratory and field investigations. From Dr. W. H. Frost the writers have received much assistance and advice. He has also reviewed the manuscript.

IN JULY ISSUE—BACILLUS CALMETTE-GUÉRIN

B. C. G. enters into the discussion whenever public health workers gather. Few definite statements are made. Much of the comment is in the realm of probability due, no doubt, to the lack of English literature on the subject. S. A. Petroff, Ph.D., in his monograph *Bacillus Calmette-Guérin (B.C.G.) Animal Experimentation and Prophylactic Immunization of Children*, prepared in collaboration with Arnold Branch, M.D., which is to appear in the July issue of the *American Journal of Public Health* and *The Nation's Health*, covers the subject fully and demonstrates his conclusions by protocols from his own work. This article should be digested by all public health officials and will interest not only this group but the general practitioner of medicine as well.

Tin Cans and Glass Jars as Bacterial Contaminants in Canned Foods*

CARL R. FELLERS, PH. D., FELLOW A. P. H. A.

Research Professor of Horticultural Manufactures, Massachusetts Agricultural Experiment Station, Amherst, Mass.

THERE are few references dealing with unused glass or tin containers as carriers of dirt and microorganisms though the study of dust and its composition has occupied the attention of such eminent pioneer investigators as Tyndall,¹ Pasteur,² Miquel³ and others. Frankland,⁴ Prudden,⁵ and Novy⁶ studied the microbiology of air and dust and together with Sternberg,⁷ Flemming,⁸ Jordan,⁹ and Conn¹⁰ demonstrated the presence of a varied microflora in air, dust and soil and pointed out the possibility of disease transmission by these means.

The dust which is found in tin or glass containers has settled largely from the air, though some contamination through contact with hands or machines may at times, likewise occur.

Experiments reported by the Hansen Machinery Corporation in coöperation with the Wisconsin Dairy and Food Commission¹¹ showed the presence of much invisible dirt in ordinary so-called "sanitary cans" previous to use. Visible dirt in cans and jars consists largely of fine soil particles, dust, coal-dust, soot, cinders, paper, grease, wood, lint and even nails, vermin excrement and insects. It is surprising how much of this debris can be found even in well stored and supposedly clean containers. Thompson¹² recommends dust-proof storage for cans and discusses proper methods and equipment for doing this. Several progressive manufacturers of canning machinery now list a number of can, jar and bottle washing machines, most of which do efficient work. Kilcourse¹³ cites very convincing data relative to glass sterilization and describes processes which have proved effective.

Few of the tin cans and only a part of the glass jars used for packing foods are washed or otherwise cleaned during the process of manufacture. For this reason there is ample chance for contamination of all kinds. Little attention has been given the matter by either sani-

* Read before the Food and Drugs Section of the American Public Health Association, at the Fifty-sixth Annual Meeting at Cincinnati, O., October 21, 1927.

NOTE: This investigation was begun in the laboratories of the Northwest Branch, National Cannery Association, Seattle, and completed at the Massachusetts Agricultural Experiment Station, Amherst.

tarians or packers. Where there is visible dust, debris or other foreign matter in containers, it may be assumed that microorganisms are present. The purpose of this paper was to determine the numbers and types of the latter.

METHODS

Cans were obtained from 29 canneries and 3 container manufacturing plants. Seven of the canneries were located in Alaska and packed salmon exclusively. The rest were widely distributed in Washington, Oregon, New York and New England. Several samples of cans stored under different conditions were usually taken at the larger plants. The cans were all average samples of containers, no effort being made to collect particularly old, dirty or exposed cans. The can samples were closed on clean double seamers and shipped directly to the laboratory. Samples of containers direct from the 3 manufacturing plants also were examined. Glass jars and tumblers of various designs were obtained from 12 food products factories some of which also used tins. Caps were placed on the glass jars and tumblers at the factories before shipping to the laboratory.

Through a small hole aseptically made in the top of the can or metal capped jar, 50 c.c. of sterile tap water was inserted. After gentle agitation, the container was allowed to stand 10 minutes and after violent agitation the small hole being closed with sterile cotton, samples were withdrawn into suitable media. Plain and Czapek agar and gelatin plates were used for aerobes, liquefiers and molds, while dextrose and lactose broth, dextrose broth oil stratified and Rettger's egg-meat medium for anaerobes, were also utilized. Incubations were made at approximately 20°, 30° and 55°C., though a small part of the cultures were not incubated at the latter temperature.

EXPERIMENTAL RESULTS

In all 279 cans and 108 glass jars from a total of 35 different canning or container manufacturing plants, were collected and examined. All samples were collected during the summer months.

Representative sizes of cans and glass jars were obtained as far as possible. The number of cans and jars of each size which were examined and the average numbers of microorganisms found in each size are systematically arranged in Table II.

Table I shows in summarized form, the relative numbers of microorganisms occurring in cans and glass jars obtained at the canneries and ready for use.

NOTE: Acknowledgment is gratefully made to E. D. Clark, R. W. Clough, O. E. Shostrom, and W. H. Spaulding of the Northwest Branch, National Canners Association, Seattle, and to R. L. France of the Department of Bacteriology and Physiology, Massachusetts Agricultural College, Amherst, for assistance during the progress of this investigation.

TABLE I
SUMMARY OF RESULTS OF MICROBIOLOGICAL EXAMINATION OF UNUSED CANS AND JARS

Location of plants	Principal products packed	No of factories	No of con- tainers examined	Storage conditions	Percentage of plants with can wash equip	Acrobic micro-organisms per can or jar			Percentage of cans or jars containing			Thermo- philes (pre- sumptive)	Colon group

Cans for Salmon—Cans were not washed previous to filling at any of the salmon canneries where samples were obtained. Some plants, particularly the larger ones in Alaska, manufacture their own cans early in the season and store them in the can loft for use after the salmon run begins. These cans may remain stacked several months, and occasionally even a year or more. Storage conditions for salmon cans ranged from poor to fair; few canneries used sufficient care in protecting their empty cans.

In general the one-half pound and one pound flats are shipped to the canneries in boxes or cases and are better protected than the talls. At most, burlap or tarred paper coverings are the rule in most canneries.

There was great individual variation among the cans tested both from the same and from different canneries. The maximum average count was 160,000 bacteria and 12,000 molds, from a cannery located on the Columbia River in a windswept, dusty region. Otherwise there is little variation in counts so far as locality is concerned. Some of the Alaska canneries showed very low counts, others fairly high. Though there is little dust (from soil) along the northwest and New England coasts, the very fact that humidity is high, possibly causes the cans to retain in viable condition whatever germ life does gain entrance.

Bacteria were more abundant than molds. The most common types of the former encountered were cocci, sporulating aerobes and actinomyces. The fungi were largely various species of *Penicillium*, *Mucor*, *Aspergillus* and others. Yeasts were always abundant. Thermophiles were usually present, but inasmuch as many of the common aerobic sporulating bacilli grow also at 55°C., too much significance cannot be attached to their presence here. They were not strictly differentiated in this study. Any organism producing growth at 55°C. was called a thermophile. Likewise any bacteria which grew in deep agar stabs or on agar plates incubated anaerobically with pyrogallol were considered anaerobes. Typical clostridia, though never numerous, were frequently encountered. The colon group as indicated by lactose fermentation was present in only 6 containers or 1.6 per cent of the total *Cl. botulinum* was not found in any of the cultures.

Microflora of Fruit and Vegetable Cans—In general, cans are shipped to these canneries in box cars or trucks packed either loose or in large crates. They are often loaded and unloaded by automatic can conveyor systems, thus eliminating much handling. It is likely that being more accessible to the can making plants, stocks of cans were not stored for such long periods as was found in salmon canneries.

The principal sizes used were Nos. 2, 2½ and 10. The diameter is greater in every case than that of the pound tall salmon can. The bacterial and mold counts are also higher. Here again great variations were found among the several samples, yet it is significant that the general averages of 19,200 bacteria and 5,390 molds per can for the Northwest and 2,300 bacteria and 7,000 molds per can for New England are really relatively high, and serious contamination of the food which enters the can may readily occur from this source.

Microflora of Glass Jars—Table I shows the summarized results obtained on glass jars from several northwest and New England canneries. Usually, glass container storage was found better than tin container storage, due largely to the fact that the glasses and jars come carefully packed and well protected, direct from the manufacturers. There is consequently, less danger of contamination than in the loosely crated or boxed tins. As stated before many plants receive their tins in full car lots, in which case they have very little protection from dust.

The bacterial and mold counts in nearly all glass jars tested were considerably lower than in the case of tin cans. It is significant that in this series the molds outnumbered the bacteria. Yeasts were very commonly found. In less abundance, were actinomyces, anaerobes and thermophiles. The leading bacterial groups found, as in tin containers, (Tables I and III) were cocci and aerobic sporulating bacilli.

In Table II it was attempted to correlate the numbers of bacteria and molds to the size of the container tested. To a certain degree this was successful. The cans harboring most microorganisms were the large No. 10's with the average of 43,000 bacteria and 9,200 molds. Next came the No. 2½ size with 33,000 bacteria and 6,300 molds. In general the flat salmon cans were dirtier and contained more molds and bacteria than the talls. The reasons for this aside from greater cross-section and area, are not clear. Likewise in the case of glass jars, the larger sizes carried the larger number of microorganisms. The jelly tumblers, though of small capacity, still harbored from 240 to 3,170 bacteria besides molds and yeasts.

GROUP DISTRIBUTION OF THE MICROORGANISMS

Data on the group distribution of the microorganisms isolated were obtained as a result of careful and complete examination of all colonies and cultures on all media, at 20°, 30° and 55° C. from a total of 20 cans obtained from 6 different canneries in the Northwest and 99 cans and glass jars from various New York and New England canneries. A total of 357 cultures from the northwest canneries and

the entire New England collection were grouped as follows:

The 213 cultures of cocci were further divided into 120 chromogenic and 93 colorless ones. Sarcinae were particularly abundant as were several species of orange and yellow micrococci. Only a few short chains of streptococci were observed. This group, so far as was determined, consisted largely at least of common air saprophytes. These settle into the cans along with dust particles and being relatively resistant to desiccation remain viable for a long time.*

The sporulating aerobes constituted the second largest group with 122 cultures or 14.8 per cent of the total. These organisms were of especial interest inasmuch as the same species were repeatedly found that had been previously recovered from insterile canned salmon " *B. cereus* was probably commonest with *B. vulgatus*, *B. mesentericus*, and *B. subtilis* also abundant. The greater heat-resistance of *B. mesentericus* may easily account for its relative abundance in canned foods as compared to other species of sporulating aerobes more numerous in dust and soil. The presence of spore forming bacteria in can dust in large numbers is probably explained on the basis of spore-resistance to desiccation, nearly all spores lodged in a can or jar thus remaining indefinitely in a viable condition. Seventeen facultative thermophiles are included in this group, 10 of which grew also at 30°C.

The asporogenous bacilli, in general, were short, non-characteristic rods most of which did not liquefy gelatin. Approximately one-fourth of the cultures showed chromogenesis. The presence of the colon group was indicated in only one case, where completed tests proved positive for *Escherischia coli*. Several cultures of *Aerobacter aerogenes* were recovered. *Ps. flouescens* was not commonly found in spite of the proximity to the sea of many canneries.

The anaerobes were the usual soil types resembling *Cl. butyricum*. No putrefactive types were isolated. None proved pathogenic or toxicogenic to guinea pigs. It is quite possible and even probable that *Cl. botulinum* is often present in dust and debris in empty food containers, particularly in the Pacific states where heavy soil infestation has been found." This should be a further incentive for canners to carefully wash their containers. Cans made inland and shipped to even remote salmon or other canneries, could thus infect the canned food, if the processing were insufficient to destroy the spores.

Actinomyces are always present in large numbers in soil and dust and are probably of little significance in this connection. Nearly all species are readily destroyed at 100°C. In certain products such as canned nut meats or dried foods it is possible that actinomyces might occasionally give rise to undesirable musty odors and tastes.

Molds are very abundant in can dust, the principal genera being *Mucor*, *Penicillium*, *Aspergillus*, *Rhizopus*, *Fusarium*, *Monilia* and others. They are probably incapable of causing injury to canned foods which are heated to the boiling point, unless the seams are not tight. However, molds are very important to jelly, jam, juice, syrup and soft drink manufacturers. Many cases of spoilage have been traced to improper sterilization of jars, bottles or caps. In some samples particularly of glass jars, the molds outnumbered the bacteria.

Yeasts are usually present in air and in dust; hence their presence in empty cans and jars is but natural. Like molds, they are usually incapable of withstanding 100°C. for more than a few minutes and are not of great importance in well processed canned foods. But as in the case of molds, yeasts in the empty jar or in the caps of jars or bottles of non-hermetically sealed foods, may cause fermentation and spoilage. Yeasty spoilage in improperly processed canned or preserved fruit products is of relatively common occurrence.

SUMMARY

Laboratory examination was made of 387 unused cans and jars from 35 northwest and New England canneries and container manufacturing plants. The counts ranged from a few hundred, to 162,000 bacteria and 22,000 molds per can in one cannery. Cans or jars obtained directly from the manufacturing plants harbored fewer microorganisms than the cannery samples. Container storage conditions ranged from very poor to excellent. In nearly all plants improvements could be made. In many canneries cans or jars were not washed previous to filling with food.

The principal groups of organisms found were cocci, 28.1 per cent; aerobic sporulating bacilli, 14.8 per cent; asporogenous bacilli, 10.4 per cent; anaerobes, 2.1 per cent; actinomyces, 6.7 per cent; molds, 24.0 per cent; yeasts, 5.6 per cent; and undetermined, 8.3 per cent. Thermophiles were relatively abundant. The colon group was presumptively present in but 1.5 per cent of cans or jars.

There was little qualitative or quantitative difference in the micro-organic flora of cans or jars from the Pacific or Atlantic seaboard.

The numbers of microorganisms per can increased directly with the diameter of the can. Fruit and vegetable cans on the average contained more bacteria and molds than salmon cans.

There is grave danger of introducing certain undesirable organisms such as *Cl. botulinum* and spoilage bacteria into the canned food by the use of dirty containers. Contamination of foods such as salmon

and sardines, not ordinarily harboring this organism, may thus be brought about.

The use of unsterilized jars, caps, etc. often leads to mold or yeast spoilage in jams, preserves, bottled goods, syrups, etc.

The presence of such a numerous and varied microflora in tin cans and glass jars ready for use at canneries of food products, makes it highly desirable that all containers be thoroughly washed before filling with food.

Dr. Hideyo Noguchi Dies

DR. Hideyo Noguchi, world-famed scientist, who has been with the Rockefeller Institute for Medical Research in New York since the founding

of its laboratories in 1904, died at Accra, West Africa, May 21. He was a victim of yellow fever. He had been loaned to the Rockefeller Foundation by the Institute to go to Africa to study the relation between South American and African yellow fever.

Dr. Noguchi was born at Inawashiro, Yama County, Fukushima, Japan, November 24, 1876. In 1918, he served on the Yellow Fever Commission sent by the International Health Board of the Rockefeller Foundation to Guayaquil, Ecuador.

Among his achievements, Dr. Noguchi is credited with being the first to demonstrate *Treponema pallidum* in the brains of paretics and to transmit syphilitic infection to rabbits by means of brain tissue from persons succumbing to paresis, and for isolating the microorganism (*Bartonella bacilliformis*) from the blood of fatal cases of Carrion's disease.

Streptococcus as an Indicator of Swimming Pool Pollution

W. L. MALLMANN

Department of Bacteriology, Michigan State College, East Lansing, Mich.

THE behavior of bacteria in swimming pools although studied intensively during the past few years, is in need of further investigation. For many years, there was no well recognized procedure for testing for contamination and each bacteriologist devised his own methods of analysis with his own interpretation of what constituted dangerous water. The methods employed were generally based upon his knowledge of water bacteriology and hence were similar to, if not the same, as those which he employed in testing drinking water. Standards were developed by various individuals and later regulations concerning methods of procedure and standards were adopted by various states.

California, in 1917, was the first state to adopt regulations governing the operation of swimming pools. In 1919,¹ the California State Board of Health devised the following bacterial standard:

As a tentative standard, a total count of 1,000 colonies per c.c. on agar incubated at 37.5° C. and an Escherich's bacillus count of 1 per c. c. as set for the pool water in any part of the pool examined within 48 hours after sampling. All tests are to be made in accordance with the latest methods of the American Public Health Association.

During the years 1918 and 1919, the writer made daily examinations of the college swimming pool for the *B. coli* content and the total bacterial count to determine their value as indicators of pollution. In the course of this work, it was finally decided that with filtration and a reasonable amount of chloride of lime the *B. coli* content could be kept below 1 *B. coli* in five 1 c.c. portions and that the total bacterial count could be kept below 1,000 bacteria per c.c. This standard was adopted tentatively with the realization that it did not mean that water conforming to this standard was safe and that water not so conforming was dangerous. It was accepted merely because, under existing methods of purification it represented the highest quality of water obtainable from day to day. During the four years that this standard was in force, no cases of disease were traced to the swimming pools.

In 1923 a committee on bathing places,⁷ appointed by the American Public Health Association made the following report:

The committee is strongly of the opinion that the methods usually employed for bacterial analysis of potable waters do not show the true sanitary condition of the waters of the swimming pools. We wish at this time to emphasize strongly the need of studies of the bacterial flora of the waters of swimming pools as a basis for special methods for the sanitary analysis of such waters. Until such special methods have been worked out, we recommend that analysis be made according to the *Standard Methods of Water Analysis* of the American Public Health Association and that the following standards of quality be tentatively adopted

Sec. 5. Bacterial Count on Agar—2 days—20° C. (this count optional): Not more than 10 per cent of the samples covering any considerable period of time shall exceed 1,000 bacteria per c.c. No single sample shall contain more than 5,000 per c.c.

Sec. 6. Bacterial Count on Agar or Litmus Lactose Agar—24 hrs.—37° C.: Not more than 10 per cent of the samples covering any considerable period shall contain more than 100 bacteria per c.c. No single sample shall contain more than 200 bacteria per c.c.

Sec. 7. B. coli—Partial confirmed test: Not more than two out of five samples collected on the same day, or not more than three out of any ten consecutive samples collected on different dates to show a positive test in 10 c.c. of water.

The adoption of this tentative standard places swimming pool water on the same standard of quality as drinking water. This is justified on the grounds that bathers invariably swallow small amounts of water. As far as we know, swimming pools conforming to such a standard are safe in every respect, but unfortunately many pools fail to reach such a high degree of purity.

In adopting a standard using *B. coli* as an index of pollution it is well first to know that the microorganism indicates dangerous contamination. Is the swimming pool containing *B. coli* necessarily dangerous? Does the presence of *B. coli* indicate fecal contamination?

In drinking water, *B. coli* indicate fecal contamination, and water containing this microorganism is considered dangerous. In streams, lakes and wells, *B. coli* of fecal origin tend to decrease in number, due to adverse growing conditions. The amount of organic matter is limited and is not an available food for this organism. Further, the temperature of such water is relatively low and tends to discourage growth. In swimming pools, conditions are entirely different. A large amount of organic matter is present and in an available form for food. The temperature is high and encourages the multiplication of the bacteria present. It is possible under such conditions that *B. coli* would increase. They would thus cease to be indicators of pollution since they would tend to increase in numbers while the pathogens introduced in the fecal matter would tend to decrease and disappear altogether.

Under laboratory conditions, *B. coli* will grow abundantly in swimming pool water. Several years ago, the writer kept a culture of *B. coli*, recently isolated from feces, growing in sterile pool water by transferring to a fresh flask of water each morning from the preceding flask. At the end of 2 weeks, the last flask after 24 hours incubation, had a count of approximately 200,000 *B. coli* per c.c. Would *B. coli* grow in the swimming pool where other bacteria are present, where the pool is constantly receiving fresh pollution, and where a constant inflow of fresh water containing chlorine occurs?

In order to answer this question, a study was made of *B. coli* in the swimming pool. Before studying the behavior of *B. coli* in swimming pool water, the writer studied the flora of polluted swimming pool water, hoping to find other microorganisms indicative of body pollution. The microorganisms besides *B. coli* most commonly found were staphylococcus and streptococcus which were undoubtedly introduced into the pool by the bathers. Streptococcus was found in four pools studied. Practically every sample of water that was polluted with *B. coli* contained streptococcus.

This microorganism is used by the English for detecting pollution in drinking water. The Americans have never used this organism for testing drinking water because a negative test does not mean that the water is potable, although a positive test for streptococcus does indicate to a greater extent than one for *B. coli* that the water is unsafe. Its significance in swimming pool water was worth considering.

Last year (1925), all of the routine examinations made on swimming pool water included a test for streptococcus along with the usual *B. coli* test as recommended by the American Public Health Association. The present paper deals with the occurrence of these two microorganisms and the relation of both to the amount of pollution entering the pool.

QUANTITATIVE PROCEDURE

The method of procedure for measuring the number of streptococci is quite similar to the methods used by the English in the determination of streptococcus in drinking water. Glucose and lactose nutrient broths are used. Quadruple strength broth is used for volumes of water from 50 to 100 c.c., double strength broth for volumes from 5 to 50 c.c. and single strength broth for volumes of 1 to 5 c.c. of water. Ten c.c. of broth is placed in each tube. The following amounts of water are tested: 10 tubes containing from 1 to 10 c.c. varying by 1 c.c., 9 tubes containing from 20 to 100 c.c. varying by 10 c.c. each, 5 tubes containing 10 c.c. each and 5 tubes containing 1 c.c. each. The five 10 c.c. and five 1 c.c. samples are tested with lactose nutrient broth while the remainder

are tested with glucose broth. The broth is made according to the methods recommended by the *Standard Methods for Water Analysis*, 1925.

The tubes are incubated for 48 hours at 37°, readings being made for *B. coli* at the end of 24 hours' and 48 hours' incubation. At the end of 48 hours' incubation at 37°, the tubes are removed and kept at room temperature for 3 days to allow the streptococci to settle to the bottom of the tubes. The tubes may be centrifugalized at the end of 24 to 48 hours' incubation to throw down the streptococci. However, as the former method is more accurate and less difficult, it was adopted.

After the streptococci have settled to the bottom of the tube, the supernatant fluid is removed carefully by suction, leaving the precipitated bacteria in the bottom of the tube in the form of a thick creamy mass. A loopful of this thick mass of bacteria is smeared on glass slides, dried and stained with gentian violet. The smears are then examined under the microscope for streptococci. No attempt is made in routine procedure to isolate the streptococci. When isolations are made, blood agar plates are smeared with the sediment obtained by centrifugalizing tubes incubated for 24 to 48 hours. Pure cultures can be readily picked from these plates after 24 hours' incubation at 37° C.

RESULTS

The data presented represent for each day, the total number of tubes containing *B. coli* or streptococci considering all of the tubes tested, namely five 1 c.c. portions, five 10 c.c. portions, 10 portions ranging from 1 to 10 c.c., each portion varying from the preceding one by 1 c.c., and 9 portions ranging from 20 to 100 c.c., each varying from the preceding one by 10 c.c. amounts, making in all twenty-nine tubes containing collectively 550 c.c. of water. The data represent days when the swimming pool water had a high bacterial content which continued for 2 or more days. These periods were selected because the *B. coli* content was generally high in the evening and thus there was presented an opportunity to study the behavior of the microorganisms during the night when the only means of purification was circulation of the water through the filters. The morning samples were generally taken before the chloride of lime was added.

A. *A Study of the Pool When in Use*—A study of the *B. coli* and streptococci content of the swimming pool was made, taking samples hourly, when the pool was in use. During this period no chloride of lime was added, so the effect of the accumulated pollution could be measured by the *B. coli* and streptococci introduced by the bathers. During the morning, when there were only a few bathers in the pool, a

marked reduction of the streptococci occurred, which was paralleled somewhat by the decrease of the *B. coli*. In the afternoon, the attendance was larger and the number of streptococci increased until in the case of the 10 c.c. portions, all 5 tubes contained streptococci. The *B. coli* content did not increase to any extent; in fact, a slight decrease occurred in the three cases reported. In these cases, the increase of streptococci parallels the increase in pollution. These experiments were repeated several times with similar results.

B. *A Study of the Pool When Not in Use*—In this series of experiments a similar test was made, only over a longer period of time and represents a period when the pool was in use followed by a period when it was not in use. Single samples were collected on a Thursday night, Friday morning and night and then starting Saturday morning, a sample was taken every 3 hours throughout the day, that night and all day Sunday. No chloride of lime was added during the whole period of the test, the only means of purification being filtration which was used continuously. *B. coli* content increased materially during Thursday night and the streptococci content decreased to zero, i.e., no streptococci were found in any of the tubes. During Friday, when the pool was in use, streptococci increased to a greater extent than the *B. coli*. Friday night, both the *B. coli* and streptococci content dropped and continued to fall until 3 o'clock Saturday afternoon, when the pool was again in use. At this time, the streptococci content increased decidedly while only a slight increase of *B. coli* occurred. Shortly after, the number of streptococci decreased rapidly and at 9 o'clock Sunday night, they had practically disappeared. *B. coli*, on the other hand, although the number decreased, were still present in large enough numbers to represent a dangerous condition of the pool as indicated by the standard test. This experiment was repeated several times with similar results.

C. *Behavior of B. coli and Streptococci During the Night*—These data represent the changes occurring in the *B. coli* and streptococci content of the swimming pool during the night. Samples were taken in the morning before chloride of lime was added. In practically every case, the streptococci content dropped from a large number to a relatively small number in the morning. The *B. coli* content was more or less erratic; however, there was little or no decrease during the night, despite the fact that during the night the filters were in continuous operation. The average decrease of streptococci amounted to 66.5 per cent while in the *B. coli*, the average decrease was only 0.6 per cent. This indicates that the *B. coli* must have multiplied in the pool, for the filters remove a large number of microorganisms and would thus have

caused a marked reduction in numbers unless the organism actually reproduced in the pool. The reduction of streptococci, on the other hand, indicates that they do not grow. The data do not necessarily indicate that they die out in the pool, since they may be removed by filtration, but the data do prove that the streptococci content parallels the pollution.

CONCLUSIONS

1. *B. coli* content is not a universally reliable indicator of intestinal pollution in swimming pools.
2. Streptococci are constant indicators of intestinal pollution and the number found in the pool parallels the amount of pollution as indicated by the number of bathers.
3. *B. coli* tend to multiply in the swimming pool, while streptococci do not.
4. Streptococci when present indicate an unsafe condition of the swimming pool.
5. *B. coli* do not necessarily indicate pollution or danger, although the absence of *B. coli* is an excellent index of safety.

Santa Monica Health Center, Los Angeles County, California

Herman Kiefer Hospital, Detroit, Mich.

THE new unit of the Herman Kiefer Hospital, being constructed at a cost of 3 million dollars, will offer several unique innovations in the arrangement and management of a city hospital. The Herman Kiefer Hospital is operated by the Detroit Health Department and when the new unit is open for occupancy in October, adding 500 beds, the hospital will accommodate 1,100 patients. This hospital is used entirely for the hospitalization of cases closely associated with the work of the city health department. Acute contagious diseases and certain types of tuberculosis are taken care of there. A maternity service is also operated which forms a connection between the prenatal and infant welfare divisions of the Health Department.

There will be no wards in the new unit and not more than 2 patients will be accommodated in a room. Each room will be supplied with running water and there will be several bathrooms installed on each floor.

The new health department laboratory will occupy one entire wing on the first floor, and certain services, such as media preparation, etc., will be provided for in the basement. This laboratory, promising to be one of the best equipped public health laboratories in the country, will be in charge of Prof. John F. Norton, now of the Department of Bacteriology, University of Chicago. Professor Norton succeeds Dr. Roy W. Pryer, who recently resigned.

Also on the first floor of the new unit will be the main tuberculosis clinic of the Health Department and the clinic of the Division of Cancer Control, which was organized more than a year ago.

The top floor will be devoted to surgery and heliotherapy departments. There will be 4 major operation rooms and 2 heliotherapy departments. The heliotherapy departments, located at either end of the building, are divided into 3 divisions, the first for treatment by artificial light, the second where patients will be exposed to the sun through quartz glass, and the third for treatment by direct exposure to the sunlight.

When the new unit is opened, visitors will be asked to leave their street garments in a gown room and before entering a patient's room will be provided with sanitary and sterilized gowns to cover their clothing. This system will be inaugurated by hospital authorities with two objectives in mind—to minimize the opportunity of the importation of infection, and to remind visitors that they are in a hospital where the most minute details of sanitation are carried out.

HELP RECTIFY A LONG STANDING WRONG

OF more than usual interest is the Copeland-Wainwright Bill now before Congress. It is designed to acknowledge in a substantial way the services of those who took part in the yellow fever experiments conducted by the board of which the late Dr. Walter Reed, of the U. S. Army, was Chairman. Of this board, only a single member is now alive, one—Dr. Lazear—having died of yellow fever in Cuba, and another—Dr. Carroll—having suffered a severe attack of the disease from the effects of which he never entirely recovered. Walter Reed died of appendicitis, but this does not lessen the credit due him for having experimented upon himself, and does not take away from the country the obligation of making adequate provision for his widow.

We make no invidious distinction in saying that the private soldiers, who underwent experiments requiring a greater degree of courage even than going over the top, deserve especial credit. Some of them have frequently been mentioned and are fairly well known, but only recently, through the efforts of the American Association for Medical Progress, another name unknown to most of us has been added. Dr. Reed said: "In my opinion this exhibition of moral courage has never been surpassed in the annals of the Army of the United States."

The bill in question not only provides for a pension of \$250.00 a month for the widows of three of the members of the original board, and for the fourth—Dr. Agramonte—who escaped infection, but also for the soldiers who allowed themselves to be experimented upon. The bill also empowers the Smithsonian Institute to make recommendations to Congress in similar cases in the future, and awards of different types may be given.

In almost any other country in the world, such conduct would have been promptly and adequately rewarded, but our government has allowed more than twenty-five years to pass with practically no recog-

nition of the great services rendered, which resulted in the elimination of yellow fever, the saving of thousands of lives of our citizens and the addition of millions of dollars worth of commerce during the summer months. Legislation of this character was strongly urged as early as 1906, but beyond a meager pension to one or two persons, nothing has been done. At present, several of those who carried out the most courageous experiments are suffering and in actual physical want. We urge on our readers that they write to members of the Senate and House Committee on Military Affairs and to their Senators and Congressmen urging as strongly as possible the favorable consideration of the bill now before Congress.

NEW LIGHTS ON MOONSHINE

AS in politics, so in medicine and public health does the question of alcohol seem to have the power of constantly coming to the front under new phases. Three recent articles¹ present to the average reader a new point of view concerning bootleg or moonshine liquor.

There seems to be no question that methyl alcohol has been used to dilute the illegal product, and to this poison many cases of blindness and of death have been attributed. The poisonous effects of methyl alcohol are well proved. Methyl alcohol is not now so much in evidence, if we accept the findings in the State of Massachusetts as representative of the illicit trade for the country in general, justification for which is at least indicated in one of the articles referred to. Lythgoe, Director of the Food and Drug Division of the Massachusetts Department of Public Health, gives the results of a long series of analyses of illicit liquors. In 1926 and 1927 only a very small percentage contained methyl alcohol, and in practically all of these the amount was small. The average amount of ethyl alcohol in samples seized during 1921, and those collected in 1927, is almost the same, differing only by 0.02 per cent, but there is a general tendency in the more recently collected samples to a lower alcoholic content, the trend being to run between 24 and 35 per cent, whereas in 1921, a larger percentage of samples ran between 35 and 50 per cent.

The studies by Dr. Reid Hunt, who examined one hundred samples of illicit liquor furnished to him by the Department of Public Health of Massachusetts, gives results which will doubtless be surprising to many. He found that the only poisonous substance of any significance was ethyl alcohol, and that the poisonous properties of samples ran closely parallel to their content of ethyl alcohol. He states that he knows of no analyses or experiments which indicate that any substances are present in illicit liquor which are more poisonous than ethyl

alcohol itself. In three cases in which death was attributed to "poison whiskey," no poison was found, but in two, more than 60 per cent, and in one, 80 per cent, of ethyl alcohol was present. In other words, death occurred from ethyl alcohol in large doses.

Another most interesting finding is that ethyl alcohol which contains a certain amount of methyl alcohol is less poisonous than pure ethyl alcohol of the same strength. He points out that methyl alcohol has a weaker action on the higher nerve centers. He also found that genuine "bottled in bond" whiskey, and whiskey of approved "medicinal quality" were slightly more toxic than ninety-seven of the hundred illicit liquors supplied to him. In the three samples excepted, the greater toxicity was due to the higher content of ethyl alcohol.

He concludes that the question is one of ethyl alcohol rather than of good or bad liquor, and that "good grain alcohol" is the substance which causes acute poisoning and death, this statement applying with equal force to the illicit product and the so-called medicinal whiskey.

He points out further that substances distinctly more dangerous than methyl alcohol have been proposed as substitutes for ethyl alcohol in food products, just as the revenue laws some twenty-five years ago led to the substitution of methyl alcohol with disastrous results.

Ethyl alcohol occupies a unique position in respect to the animal body. It is practically the only known substance foreign to the body which in moderate amounts is easily and quickly rendered harmless, the body being able to make use of ethyl alcohol while destroying it. Dr. Reid says: ". . . Entire nations derive as large a part of their food from alcohol as from meat and other sources of proteins."

The Commissioner of Health of Massachusetts comments on the two articles considered, asking why the death rate from alcohol has increased so tremendously since 1920. The answer does not seem entirely clear, but one reason is suggested which accords with observations made by many. As he puts it, the tendency is to "drink it while you've got it." Observations made in parts of Canada where liquor is now legally sold, indicate that, during the period of prohibition, the habit of drinking light wines and beer was lost, and although these may now be obtained, strong drink is preferred by many. The same thing is probably true for the United States. When there is difficulty and legal danger in obtaining alcoholic beverages, the average man is inclined to get the most kick possible for his money, and to get it as quickly as possible. Unfortunately the kick is often in a vital spot, and of such force as to end in death.

THE CONFERENCE ON PUBLIC HEALTH

IN 1927 the trustees of the American Medical Association called a Conference on Public Health, the result of which encouraged them to call a second conference in 1928, on March 30 and 31, at the headquarters in Chicago. The attendance was fairly large and included representatives from many organizations interested in the promotion of public welfare.

The program for the first day included only two subjects—Free and Part Pay Clinics, and The Health Demonstration. The papers of those who discussed these questions were ably prepared and unquestionably produced a profound impression on the audience. The discussion which resulted, however, was confined largely to the demonstrations held at Mansfield, O., and in Cattaraugus County, N. Y., and developed considerable heat. As one who took part said, many such discussions “result in much heat, but little light.” Unfortunately the discussion of the Cattaraugus County situation was limited to one side, since there was no one present to answer for the physicians concerned, some of whom were handled in rather severe fashion. The Health Demonstration, which was a masterly presentation of well planned and well conducted enterprises in four widely separated parts of the country, received practically no discussion, the two first mentioned cases having absorbed practically the entire attention of those who wished to talk and to be heard.

On Saturday a study of 3781 surveys was given. These included practically every type of survey, carried out by many different agencies, in practically every state of the Union. The speaker gave the impression that he was not very favorable to surveys as they have been conducted in the past, because there was little uniformity in objectives or accomplishments. Why surveys should be uniform in these respects was not shown.

There can be little question that friction has developed over health demonstrations given by private agencies; there has been lack of judgment on the part of some promoters as well as those employed in conducting the demonstrations. The nurses employed have been charged with prescribing, and with making statements which directly or indirectly discredited the medical profession of the community. The Health Commissioner of New York City is reported as having said that these privately conducted demonstrations were “sapping the strength of the official health body.” The president of the Ohio State Medical Association, who read one of the papers in the conference under discussion, was strongly of the opinion that such demonstrations were apt to lead to lack of self-respect, communism and state medicine,

in addition to discrediting the medical profession, which, he said, must always of necessity lead in such work.

The law has wisely put the medical man in charge of health matters practically everywhere, and there should be no competition with the medical profession. On the other hand, medical men acknowledge freely the assistance of those outside of the profession. They cannot, for example, forget the services of Pasteur, Chadwick and Shattuck, but it seems clear that the average man who has not been trained in the study of disease, and has not come into actual contact with it, cannot understand, and probably never will, the attitude of the man who has made it his life work.

Shortly before the conference adjourned, a better spirit was shown by those, the tone of whose discussions had been perfervid. It was agreed that both parties were equally honest and sincere, while both had the same ultimate object in view. It was finally decided that a committee be appointed, made up of members of the various organizations represented, which will discuss the entire matter in an effort to crystallize the spirit of coöperation, to agree upon fundamentals by which a better understanding may be reached, and plans for coöperative work in localities be made. The members of this committee are to report to their constituent organizations as well as to the board of trustees of the American Medical Association. We can only hope that good results will follow.

LETTER TO THE EDITOR

TO THE EDITOR:

I have read with much interest and with great satisfaction the article entitled, "New York Leads the Way," which appeared in the April number of your JOURNAL.

It is fitting that I call attention to the fact, that a Division of Public Health Nursing has been functioning in the Boston Department of Health since March, 1926.

All of the nurses are under the direc-

tion of Miss Hazel Wedgwood, a highly qualified nurse who has been efficiently developing a generalized nursing service. Our plan and method of operation have been discussed with Dr. Harris.

You will perhaps care to call attention to our nursing organization in a future number of the JOURNAL.

F. X. MAHONEY,
Health Commissioner.

Boston, Mass.,
April 23, 1928.

ASSOCIATION NEWS

THE AMERICAN PUBLIC HEALTH ASSOCIATION IN CHICAGO

WHAT promises to be the most stimulating meeting from the professional and scientific standpoints in the history of the A. P. H. A. is the 57th Annual Meeting to be held in Chicago, Ill., October 15-19, with headquarters at Hotel Stevens.

A departure from the usual procedure in former years will be the participation of two other national health organizations, the American Child Health Association and the American Social Hygiene Association, who will meet jointly with the A. P. H. A. This will be the 5th annual scientific meeting of the American Child Health Association, and a special meeting of the American Social Hygiene Association.

Other related organizations meeting in Chicago that same week will be the State Laboratory Directors and the Conference of State Sanitary Engineers.

In planning the program, the Central Program Committee has increased the number of days of the meeting in order to give more time for the inspection of Chicago's many points of interest. There will be a total of 42 sessions including 3 general sessions, 31 sessions of the sections and 4 special sessions devoted to: Cancer, Training for the Public Health Profession, Dairy Products, and Epidemiology; 4 joint sessions bringing together these sections: Health Officers, Public Health Nursing, Child Hygiene; Laboratory and Food, Drugs and Nutrition; Laboratory and Public Health Engineering; Child Hygiene, Public Health Education, and the Health Education Division of the American Child Health Association. Only the tentative program is submitted here to our readers.

GENERAL SESSIONS

At the first general session to be called Monday evening at 8:30 o'clock, an address will be made by Herman N. Bundesen, M.D., President of the A. P. H. A., and a similar address from the American Child Health Association. The second general session scheduled for Wednesday evening will be devoted to discussions of the following: "Our Organizations for the Care of the Sick," "Which Public Health Procedures Pay?" and "How To Use Effectively Civic Groups in Promoting Health Programs." These subjects will be presented by eminent authorities in the field of public health. The third general session, scheduled for Thursday evening, will be in charge of the Local Committee when a banquet will be held, followed by dancing.

SPECIAL SESSIONS

As one of the special sessions the Committee on Training and Personnel has arranged a dinner meeting to discuss "Minimum Training for All Persons Entering the Public Health Professions." Prof. C. E. Turner of Massachusetts Institute of Technology will preside, and the discussion will be opened by John Sundwall, M.D., director of Hygiene and Public Health, University of Michigan.

JOINT SESSIONS

The program arranged for the joint session of HEALTH OFFICERS, PUBLIC HEALTH NURSING and CHILD HYGIENE SECTIONS in conjunction with the American Child Health Association is: Studies on Infant Mortality. GEORGE T. PALMER, Dr.P.H., and

DOROTHY F. HOLLAND, Ph.D., American Child Health Association, New York, N. Y.

Discussion: PHILIP VAN INGEN, M.D., New York, N. Y.

Pediatric Service in the City Health Department Centers Provided By Medical Schools in Boston. HAROLD C. STUART, M.D., School of Public Health, Department of Child Hygiene, Harvard University, Cambridge, Mass.

Result of the 1927 Summer Round-Up Campaign of the National Congress of Parents and Teachers.

Symposium on Preschool Health Supervision Procedures to Reach the Children and Maintain Supervision

In the Small Towns and Rural Areas by a State Health Department (New York State Department of Health), ELIZABETH GARDINER, M.D., State Department of Health, Albany, N. Y.

In a Small City (Fargo, N. D.). LESTER J. EVANS, M.D., Medical Assistant, Child Health Demonstration, New York, N. Y.

In a Limited Area of a Large City (East Harlem Health Demonstration). GRACE L. ANDERSON, R.N., East Harlem Health Center, New York, N. Y.

The subjects and speakers for the joint session of the LABORATORY and FOOD, DRUGS and NUTRITION Sections are:

The Use and Interpretation of the Hydrogen Ion Determination in Food Control. W. A. TAYLOR, M.D., LaMotte Chemical Products Company, Baltimore, Md.

The Disinfection of Carbonated Beverages and Water Containers. JAMES P. KILCOURSE, Chief Bureau of Inspection, Department of Health, Chicago, Ill.

Research in Sewage and Industrial Wastes Disposal will be the main topic for the consideration of the LABORATORY and PUBLIC HEALTH ENGINEERING Sections at their joint sessions when the following papers will be presented:

Some Bio-Chemical Factors in Sewage and Sludge Treatment. WILLEM RUDOLFS, Director New Jersey Experiment Station, New Brunswick, N. J.

Experiments on Stream Flow Aeration in the Purification of Beet Sugar and Packing House Wastes. MAX LEVINE, Ph.D., G. H. NELSON and HARRY N. JENKS, Iowa State College, Ames, Ia.

Bio-Chemical Oxidation of Phenolic Wastes. FLOYD MOHLMAN, Chief Chemist, Chicago Sanitary District, Chicago, Ill.

At a joint session of the CHILD HYGIENE and PUBLIC HEALTH EDUCATION Sections with the HEALTH EDUCATION DIVISION of the A. C. H. A. an "Analysis of Efforts to Date to Define Objective Standards in Health Education" will be given by JAMES F. ROGERS, M.D., U. S. Bureau of Education, Washington, D. C.

SECTION MEETINGS

Health Officers—This section will hold 3 sessions, one of which will be devoted to Rural Health work.

Laboratory—At the first session of this section reports of the section committees will be given. The second session will be devoted to a symposium on "Undulant Fever" and at the third session, five papers of general interest to the section members will be read.

Vital Statistics—Accidents will be the main theme of the first session of this section. This will embrace accidents in industry, in the home, and public accidents. The second session will be given over entirely to sectional committee re-

ports. The papers to be presented at the 2 remaining sessions are:

Extent to Which Residence Influences the Recorded Death Rates from Cancer. J. V. DEPORTE, PH.D., State Department of Health, Albany, N. Y.

Reallocation of Non-Resident Deaths. WILLIAM C. WELLING, State Board of Health, Hartford, Conn.

Relation of Climate to Tuberculosis. ROBERT BRUCE WATSON, Newark, N. J.

The Mortality from Diphtheria According to Place of Death. DONALD B. ARMSTRONG, M.D., Metropolitan Life Insurance Company, New York, N. Y.

Practical Use of Vital Statistics in the Establishment of Neighborhood Health Work in New York City. G. J. DROLET, Statistician in charge Research Service, New York Tuberculosis and Health Association, New York, N. Y.

Vital Statistics in Insurance. EDWIN W. KOFF, Metropolitan Life Insurance Company, New York, N. Y.

The Elimination of the Normal Seasonal Components in Obtaining Epidemic Cycles. G. E. HARMON, M.D., Western Reserve University, Cleveland, O.

Total Morbidity Data in New York City, 1866-1927. HAVEN EMERSON, M.D., Columbia University, New York, N. Y.

Public Health Engineering—Symposia on "Sterilization of Milk Utensils," "Shellfish Sanitation," and "Methods of Financing Water Supply and Sewerage Improvements," have been arranged by this section. The subjects of atmospheric pollution by smoke and odors, useless noises and their relation to public health, and school room ventilation and absenteeism will be taken up at

other sessions of this group. A practical problem to be presented at one of these sessions will be "Carbon Monoxide Pollution of Air in Chicago" by JOEL I. CONNOLLY, M. J. MARTINEK, and J. J. AEBERLY of the Chicago Department of Health. The engineers have also planned a dinner session and a luncheon business session.

Industrial Hygiene—Industrial hygienists attending the Annual Meeting will have an opportunity of hearing the most pertinent phases of industrial hygiene today discussed by prominent investigators and authorities. This section has planned 3 sessions for its members, one of which will be given over to section reports. The programs for the other 2 sessions will include:

Industrial Fatigue (Including Report of Committee on Industrial Fatigue). *Chairman*, EUGENE L. FISK, M.D., Medical Director Life Extension Institute, New York, N. Y.

Mortality Trends in the Industrial Population. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Development of Reports on Occupational Mortality. WILLIAM M. STEUART, Director U. S. Census Bureau, Washington, D. C.

Discussion: L. R. THOMPSON, M.D., U. S. Public Health Service, Washington, D. C.; DEAN K. BRUNDAGE; EUGENE L. FISK, M.D., Medical Director Life Extension Institute, New York, N. Y.

Public Health and Medical Work in a Large Coal Company. D. J. KINDEL, M.D., Medical Director, The Consolidation Coal Company, Fairmont, W. Va.

Discussion: LLOYD NOLAND, M.D., Tennessee Coal, Iron and Railroad Company, Birmingham, Ala.

The Possible Relationship of Mu-

tual Benefit Associations to the Health of Employes. SETH L. BUSH, Crocker-McElwain Company.

Mobilizing Mutual Benefit Associations to Include Health Activities.

Discussion: MEYER BLOOMFIELD, Consultant on Industrial Relations, WILLIAM A. SAWYER, M.D., Rochester, N. Y.

Extension of Industrial Hygiene by Tuberculosis Associations in the United States. BERNARD S. COLEMAN, Executive Secretary Hudson County Tuberculosis League.

Discussion: WADE WRIGHT, M.D., Metropolitan Life Insurance Company New York, N. Y.; EMERY R. HAYHURST, M.D., Ohio State University, Columbus, O.

House Organs and Their Relationship to the Health of Employes. MEYER BLOOMFIELD, Consultant on Industrial Relations.

Health Education in an Industrial Plant. J. B. GIBSON, Director of Safety and Health, Western Electric Company, Chicago, Ill.

The Tuberculous Worker and His Placement in Industry. C. W. BERGQUIST, President Chicago Tuberculosis Institute, Chicago, Ill.

Discussion: E. B. HUNT; VOLNEY S. CHENEY, M.D., Armour & Company, Chicago, Ill.

For a luncheon session a round-table discussion on "Industrial Fatigue" has been planned.

Food, Drugs and Nutrition—This section will follow its usual procedure of devoting one session to business and sectional reports. The papers scheduled for the other session are:

Health Significance of Small Amounts of Metals. DR. J. S. MCHARGUE, Agricultural Experiment Station, Lexington, Ky.

Evaporated Milk—Its Preparation, Nutritive Value and Uses in the

Diet. DR. FRANK E. RICE, Executive Secretary Evaporated Milk Association, Chicago, Ill.

What We Should Strive for in Food Advertising. E. V. MCCOLLUM, M.D., Johns Hopkins School of Medicine, Baltimore, Md.

Ice Cream Control. DR. F. W. FABIAN, Research Associate in Bacteriology, State College, East Lansing, Mich.

Child Hygiene and American Child Health Association—The first session of the Child Hygiene Section will be a joint meeting with the American Child Health Association to discuss "Maternal Mortality." The report of the Section Committee to Study the Problem of Infant and Maternal Mortality will be given by JULIUS LEVY, M.D., Newark, N. J.

BLANCHE M. HAINES, M.D., U. S. Department of Labor, Children's Bureau, Washington, D. C. will make a report of the Children's Bureau Meeting held in Washington in the spring to consider maternal mortality.

LILLIAN R. SMITH, M.D., State Department of Health, Lansing, Mich., will lead the discussion of this subject.

CARL DAVIS, M.D., Secretary, Section of Gynecology, Obstetrics and Abdominal Surgery, American Medical Association, Milwaukee, Wis. will give a report of that section, and WILLIAM DANFORTH, M.D., American Gynecological Society, Evanston, Ill., will preside at the discussion.

HAZEL CORBIN of the Maternity Center Association, New York, N. Y. will tell about the work being done by the Maternity Center Association in Tioga County.

"School Medical and Nursing Service" will be the subject of another session of the Child Hygiene Section. WALTER S. CORNELL, M.D., Director, Medical Inspection of Public Schools, Philadelphia, Pa., and Ann Dickie Boyd,

Director of Nursing, Bureau of Education, Denver, Col., will discuss the "Improvement of Measures for the Correction of Physical Defects." E. H. LEWINSKI-CORWIN, Ph.D. will discuss "School Medical Service in a Continuation School" and another speaker will be asked to present the part that the teacher must take in such a program.

The third session of the Child Hygiene Section will be for the consideration of "School Medical and Nursing Service." OTIS B. NESBIT, M.D., Director of Medical Inspection, Gary Public Schools, Gary, Ind., will talk on "Sickness and Absence Record in the School Health Program Methods and Procedures and the Values Resulting." and HAVEN EMERSON, M.D., Professor of Public Health Administration, College of Physicians and Surgeons, New York, N. Y., will lead the discussion.

The fourth session of the Child Hygiene Section and the A.C.H.A. will be devoted to Dental Hygiene. Objectives in dental health education will be the major topic. Clinics on dental health education material will be conducted by a school dentist and an educator.

Public Health Education—Last year this section found its luncheon discussion meetings most advantageous from several points of view and so again this year it will hold one dinner and two luncheon sessions for the informal discussion of successful procedures in health education, and for the exchange of ideas and accomplishments.

At one luncheon session, PROF. F. N. FREEMAN, University of Chicago, Chicago, Ill., will make an analysis of letters sent to health editors, and at another luncheon session MARY L. HAHN, State Department of Health, Springfield, Ill., will give a "Program for Health Education Training in Teachers' Colleges."

"Fundamentals of a Health Education Program" has been selected as the

subject for the formal session of this section. H. E. KLEINSCHMIDT, M.D., National Tuberculosis Association, New York, N. Y. will discuss the "Choice of Objectives and Subject Matter in Preparing Health Education Programs." HOWARD W. GREEN, Secretary, Cleveland Health Council, Cleveland, O., will talk on "The Selection and Grouping of Audiences" and IAGO GALDSTON, M.D., New York Tuberculosis and Health Association, New York, N. Y. will discuss "Mental Attitudes."

Public Health Nursing—At this time the Public Health Nursing Section has not completed its program. The section will have 2 sessions, however, one being devoted to section reports, and another to the subject of "Staff Education" when AMELIA GRANT, R.N., Director, Bureau Public Health Nursing, New York City Department of Health, will speak.

AMERICAN CHILD HEALTH ASSOCIATION SESSION

A meeting of the Health Education Division of the A. C. H. A. is also planned to meet the needs of teachers, and will be built around the subject, "Basic Correlation in Classroom Teachings."

AMERICAN SOCIAL HYGIENE ASSOCIATION SESSIONS

The American Social Hygiene Association has prepared the following tentative program, the speakers to be announced later:

Luncheon Session

Administrative Problems Indicated by Venereal Disease Incidence Studies

Scientific Session

The Program for Syphilis Research in the United States

Public Session

The Progress of Social Hygiene and the Efforts of Official and Voluntary Agencies in this Connection

A. P. H. A. ASSISTS IN CHAUTAUQUA HEALTH PROGRAM

HEALTH from the personal and community viewpoints will be presented from the Chautauqua platforms of the Swarthmore and Redpath Chautauqua Circuits this summer in 289 towns in 15 states in the mid-eastern section of the United States. The Chautauqua health program was inaugurated by the Milbank Memorial Fund of New York and the National Community Health Association, at the request of the Milbank Memorial Fund, has agreed to undertake a part of the organization and direction of the health education program. Coöperating in this plan will be the American Child Health Association, American Red Cross, National Tuberculosis Association, secretaries of state tuberculosis associations and state health commissioners of the states included in the circuits.

The states embraced in this Chautauqua health program are:

Indiana	Connecticut
Ohio	Massachusetts
West Virginia	New Hampshire
Kentucky	Vermont
Maryland	Delaware
New Jersey	Virginia
New York	Rhode Island
Pennsylvania	

Upon authorization of the Executive Board, the A.P.H.A. has appointed the following Committee on Chautauqua Health Program: S. J. Crumbine, M.D., Chairman; Donald B. Armstrong, M.D., Bertrand Brown, H. E. Kleinschmidt, M.D. and E. H. Marsh, M.D. This committee will direct the collection and use of material on public health to be used by the lecturers. One of the responsibilities of this committee will be to obtain detailed information concerning health conditions in the cities and towns to be visited by the lecturers, so that to a certain extent, the general public health principles can be applied to the specific problems of the communities.

It is the aim of the coöperating groups to give impetus to public health through the Chautauqua program so that the communities will themselves undertake some definite public health work. The committee also hopes to increase the scope of service of the local, state and national health organizations in relation to the individual community health programs.

Dr. Edward T. Devine, Dean of the Graduate School, American University, Washington, D. C. and Dr. David D. Vaughan, professor of Social Ethics of the Graduate School, Boston University, will be the speakers on community health for the Swarthmore Chautauqua, and Marie Dohm and Helen Stacey of the American Red Cross staff will be the lecturers on personal health.

On the Redpath Chautauqua Circuit, Wallace Bruce Amsbary of the Armour Institute of Technology, Chicago, Ill., and Frederick M. Snyder, social investigator of Lima, O. will be the two lecturers.

A program to interest the children of the community will be conducted by the Junior Chautauqua leader in each town. The special feature of the Junior Chautauqua program this year will be the presentation of a "Health Minstrel" prepared by Mary L. Flynn, director of Junior Work for the Swarthmore Chautauqua Association. The children will dramatize health principles at the meetings of Junior Town.

EMERY R. Hayhurst, M.D., Fellow A. P. H. A., Secretary of the Industrial Hygiene Section and a member of the Editorial Board, will represent the American Public Health Association at the Congress of the Royal Institute of Public Health, University of Dublin, Dublin, Ireland, August 15-20. He is one of the vice-presidents of the Congress and will read a paper on "Occupational Diseases."

He will also represent the Association

at the 5th International Medical Congress for Industrial Accidents and Occupational Diseases at Budapest, Hungary, September 2-8, and will read a paper on "Silicosis." He is joint chair-

man of the Committee for the United States of this congress, and one of the 2 permanent members of the International Committee, which position he has held since 1914.

NEW MEMBERS

- Pedro José Almazán, M.D., Montgomery, Ala. (Assoc.)
- Philip K. Bates, S.B., Dayton, O., Research Worker on Food Preservation and Health, Frigidaire Corporation
- William Roscoe Berry, Norfolk, Va., Chief Inspector and Bacteriologist, Bureau of Shellfish Sanitation, State Department of Health
- Joseph Colt Bloodgood, B.S., Baltimore, Md., Chairman Maryland Cancer Committee
- V. G. Bonham, M.D., Fayette, Mo., County Health Officer
- F. F. Bowman, M.D., Madison, Wis., Health Officer
- Esther L. Branch, Chicago, Ill., Lecturer on Education Subjects, The Best Foods, Inc.
- Joseph T. Brennan, M.D., Independence, Mo., Health Commissioner Jackson County (Assoc.)
- Russell Broughman, Orlando, Fla., District Sanitary Officer, Bureau of Engineering, State Board of Health
- Harriet Brydon, New Liskeard, Ontario, Can., Victorian Order Nurse and School Nurse
- Ora Ann Carl, Flat River, Mo., County Public Health Nurse
- Manton M. Carrick, M.D., Dallas, Tex., Director of Public Health
- Alice M. Childers, R.N., Farmington, Mo., County Public Health Nurse
- Iva M. Church, B. S., Detroit, Mich., Nutrition Director, Detroit Dairy and Food Council
- Margaret W. Davison, Maryville, Mo., County Public Health Nurse
- Helen Louise Delano, R.N., Boston, Mass., Industrial Nurse, Boston Rubber Shoe Company
- C. M. Derryberry, M.A., New York, N. Y., Research Assistant, American Child Health Association
- Alva J. Drake, M.D., Lancaster, Mo., County Health Officer
- Raymond E. Duckworth, D.V.M., Berkeley, Calif., Field Veterinarian, State Department of Agriculture
- Helena A. Dunham, R.N., Kansas City, Mo., Supervising Nurse, Jackson County
- John Engelbrecht, M.D., Stony Hill, Mo., County Health Officer, Gasconade County
- Charles Hall Farmer, M.D., Lakeland, Fla., City Health Officer
- Elisha Fowler, Reading, Mass., (Assoc.)
- Royal L. Garner, M.D., Milan, Mo., County Health Officer
- James Gibbard, M.S., B.S.A., Ottawa, Ontario, Can., Bacteriologist, Department of Health Laboratories
- Edith Doris Hagerman, Beaver Falls, Pa., Industrial Nurse, Babcock and Wilcox Tube Co.
- Philip Abbot Herrick, New York, N. Y., Director, Scientific Department, Merrell-Soule Co., Inc.
- Louise K. Lauermann, R.N., Columbia, Mo., County Nurse
- Camilla Laws, B.S., Chicago, Ill., with Calumet Baking Powder Company
- James R. Lee, M.D., Charleston, Mo., County Health Officer
- Elizabeth B. Lundy, A.B., New York, N. Y. (Assoc.)
- Edith Hanson Marcham, R.N., Plainville, Conn., Industrial Nurse, Trumbull Electric Co.
- James H. McCall, M.D., Moundsville, W. Va., City and County Health Officer
- William Arthur McGraw, Flat River, Mo., Sanitary Inspector
- L. B. McPheeters, Charleston, Mo., Sanitary Inspector
- Ruth Esther Mettinger, R.N., Jacksonville, Fla., Nursing Field Representative, Georgia and Florida American Red Cross
- Gertrude O. Murphy, R.N., Bonne Terre, Mo., County Nurse
- Bertha E. Nettleton, New York, N. Y., Direc-

tor Research Department, Childs Company
 Ralph E. Noble, Chicago, Ill., Bacteriologist
 Chicago Health Department

Nellie Ogilvie, Bernardsville, N. J., Director
 Visiting Nurse Association of Somerset Hills

Charles Hewlett Peters, B.S., Kennett, Mo.,
 Sanitary Inspector Dunklin County

Anne Pierce, M.S., New York, N. Y., Editor
 Bureau of Chemistry, U. S. Department of
 Agriculture

Mabel L. Smyth, Honolulu, Hawaii, Director
 Division of Maternal and Infant Hygiene,
 and Supervisor of Nurses, Territorial Board
 of Health

Margaret Iglehart Stanford, R.N., Charleston,
 S. C., Staff Nurse, Public Health Nursing
 Service, Department of Health

Minnie Julia Strobel, Jefferson City, Mo.,
 Acting Director Public Nursing, Division of
 Child Hygiene, State Board of Health

Harry Taub, Ph.Ch., B.S., New York, N. Y.,
 Assistant Professor Materia Medica, School
 of Pharmacy, Columbia University

Euthimios H. L. Tehor-Baj-Oglu, M.D., New
 York, N. Y., Conducting public health work
 at tri-weekly clinics

Leonard O. Vose, B.Sc., M.A., Lincoln, Neb.,
 Director of Laboratories, State Bureau of
 Health

Katherine Z. W. Whipple, A.B., M.A., New
 York, N. Y., Secretary Extension and

Development Service, New York Tubercu-
 losis and Health Association

Edward Watson, Kansas City, Mo., Dairy
 Advisor

Sien Ming Woo, M.D., C.P.H., Shanghai,
 China, Post Graduate Study (Assoc.)

Alma Helena Wretling, R.N., Minneapolis,
 Minn., Director Hennepin County Public
 Health Nursing Service

Agnes I. Wright, Mount Vernon, N. Y., Direc-
 tor Mount Vernon Visiting Nurse Associa-
 tion

DECEASED MEMBERS

Arthur G. Bretz, M.D., New York, N. Y.
 Member, elected 1920.

Daniel Connelly, M.D., Health Officer, Kings-
 ton, N. Y. Member, elected 1927.

C. E. Durham, M.D., State Board of Health,
 Austin, Tex. Member, elected 1927.

Adam S. MacKnight, M.D., Bristol Co. Tuber-
 culosis Hospital, Attleboro, Mass. Fellow,
 elected 1923—Member, 1915.

F. C. Smith, M.D., Auburn, N. Y. Member,
 elected 1919.

Francis R. Smyth, M.D., Bismarck, N. D.
 Fellow, elected 1923—Member, 1912.

Margaret Tupper, R.N., The Rockefeller Foun-
 dation, Paris, France. Member, elected 1920.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Communicable Diseases in New York City—A grand total of 124,625 new cases of reportable diseases was notified to the New York City Health Department during the year 1927, as against 133,313 in 1926, and 95,222 in 1925.

Cases of venereal diseases were the most numerous of communicable conditions reported during 1927, there being 31,330 cases, of which 24,324 were syphilis, and only 7006 were gonorrhea. Scarlet fever came second on the list with 18,339 cases. This disease was much more prevalent than in the two previous years. There were 18,273 cases of pneumonia reported—a decrease of 7500 over 1926. Diphtheria furnished the fourth largest number of cases reported, 13,507 in 1927. Then followed tuberculosis with 10,873 cases. There were only 2101 cases of measles.

The above figures are compiled in a preliminary report issued by the New York Tuberculosis and Health Association, and as furnished by the courtesy of the Division of Communicable Diseases of the New York City Department of Health.—G. J. Drolet, *Prevalence of Communicable Diseases, New York City, 1927*.

Appraisal of Health Activities in Cincinnati—Figures gathered by Dr. W. H. Peters, Health Commissioner of Cincinnati, in which a comparison is made with 15 cities of larger population and 4 cities of slightly smaller population, show expenditures from 1 cent to 69 cents per capita higher than the current expenditures for Cincinnati. The latter city appropriated \$201,414.35 for public health work in 1927, which represents 49 cents per capita. With the

addition, however, of sums spent by other municipal and voluntary agencies engaged in public health work, the per capita expenditure rises to \$2.09.

Cincinnati scores 798 points out of the possible 1000 provided for by the *Appraisal Form for City Health Work* of the Committee on Administrative Practice of the American Public Health Association.

The milk and food control service of the Health Department is outstanding in personnel, direction and accomplishments. The annual summer round-up of preschool children has been an enterprise of marked success. The Public Health Federation brings together representatives of all public and private agencies in Cincinnati interested not only in preventive health work, but in the broad problem of health including dispensaries, hospitals, mental hygiene, etc. The vital statistics service of the Health Department is approximately 88 per cent adequate at the present time. There is need of a trained vital statistician.

The Health Department is responsible for the control of communicable diseases and measures instituted are in accord with best practice. Intensive immunization campaigns should be instituted and nurses should be employed for the educational instruction in connection with the control of communicable diseases. The Communicable Disease Division is given a rating of 78 per cent, while for the control of venereal diseases the community rating is 88 per cent. A more intensive follow-up system should be employed.

The tuberculosis services of Cincinnati are but 48 per cent adequate. Eight

agencies and the County Hospital assist the Health Department in providing control services. A full-time director of tuberculosis is needed, as well as additional funds for extension of nursing, medical, hospital and preventive services.

The prenatal service lacks but 17 per cent of being up to standard requirements. There is need of greater intensity of clinic service per case registered, and obstetrical nursing service should be offered to private physicians for home deliveries.

The infant hygiene service is 79 per cent complete, while the preschool service rates 100 per cent, and the school service 73 per cent.

There are 78 nurses doing public health nursing service under the direction of 10 separate and distinct agencies. The present nursing personnel is a little less than half the number required.

The sanitary work of the Health Department is well organized, lacking only 12 per cent of obtaining the maximum score, and the food and milk control services show a high degree of efficiency and receive a rating of 85 per cent of the maximum.

A full score is accorded to the laboratory, although the activities are divided among several public and private laboratories.

Popular health instruction is 70 per cent complete.

Cincinnati has made many noteworthy accomplishments in the field of public health, it being the desire to plan for a complete health program. The Out-Patient Department of the General Hospital carries a large service, a special thyroid survey among school children has been undertaken under the direction of Dr. Olesen of the U. S. Public Health Service.

Special clinics have been prepared for the negro, while the City Housing Bureau has made noteworthy progress in their particular line of endeavor.

An Appraisal of Public Health Activities in Cincinnati, Ohio, for the Year 1926, published jointly by The Public Health Federation of Cincinnati and the American Public Health Association.

Rural Health Service—On January 1, 1928, there were 414 counties in the United States with a local health service under the direction of whole-time local health officers. In 1924 there were 250 such health departments; in 1925 the number had increased to 280; in 1926 there were 307, and in 1927 there were 337. These figures all refer to the condition on January 1, in each year.

Within the period January 1, 1927, to January 1, 1928, whole-time county or district health service was established in 84 units and was discontinued in 7—a net gain of 77. In 64 instances the district was more or less inundated by floods in the Mississippi valley or in the Eastern part of Kentucky during the spring of 1927. There were created 18 new units in Arkansas, 22 in Kentucky, 16 in Louisiana, 5 in Mississippi, 2 in Missouri, and 1 in Tennessee. These projects have been developed under special arrangements between the various state health departments, the U. S. Public Health Service, and the Rockefeller Foundation.

Since 1920 the average annual net gain in the number of new county or district units has been 38. At such rate of progress about 55 years would be required for reasonably adequate whole-time local rural health service to be extended to such parts of the United States in which the service is needed. It is estimated that a reasonably adequate whole-time rural health service throughout the country would cost about 20 million dollars a year.—L. L. Lumsden, Extent of Rural Health Service in the United States, 1924-1928, *Pub. Health Rep.*, 43:861 (Apr. 13), 1928.

LABORATORY

C. C. YOUNG

SOME SEROLOGICAL STUDIES IN MALARIA*

WILLIAM H. TALIAFERRO, PH.D.

University of Chicago, Chicago, Ill.

THE serology of malaria has become a subject of intensive investigation for my coworkers and me because first, it forms an integral part of our program of studying the immunology of the blood protozoa¹ and second, it may yield a tool of prime importance in the diagnosis of the latent disease. As the members of the Association are primarily interested in the latter topic this paper will be limited to the bearing of the work on the question of diagnosis.

In spite of many valuable clinical aids the final and positive diagnosis of malaria rests upon the finding of the plasmodia in blood smears. The chances of finding the parasites have been greatly increased by the various modifications of the thick film method² first devised by Ross.³ Nevertheless, the perfection of some serological test might enable us to reach a final diagnosis of infections of such a low grade that parasites cannot be found in the thick film, and would be of interest in following the course of the disease during treatment.

Before we began our work there was considerable evidence that both precipitins and complement fixing antibodies could be demonstrated in a certain proportion of malarial cases. Omitting from consideration a long series of papers dealing with the Wassermann reaction or modifications of it, Gasbarrini,⁴ Thomson,⁵ and Horowitz-Wlassova⁶ obtained complement fixation and Pewny⁷

obtained a precipitin reaction. In view of the comparative simplicity of technic we have been attempting to perfect a precipitin test and through the financial aid and courtesy of the International Health Board and the United Fruit Company we have made two trips to Tela, Honduras, to test our results under tropical conditions.⁸

By far the most difficult technical obstacle in work of this kind is the preparation of a suitable "antigen"[†] for the tests. In our first work at Tela we carried out 1605 precipitin tests with 37 different "antigens" on the serums of 535 persons. This was supplemented in our second trip by 1438 precipitin tests with 75 different "antigens" on the serums of 298 persons. All of the efficient "antigens" have been made with aqueous extracts containing large amounts of malarial protein. The best source of malarial protein has been from placentas of patients infected with *Plasmodium falciparum* where there is a placental localization of the parasites. In our first work⁸ we believed that infected peripheral blood, particularly after cultivation to increase the size of the parasites, might be just as efficient a source. Later work, however, did not bear this out as we have never obtained as good results with blood as with infected placentas. In comparing these two sources of malaria protein we concentrated the parasites from both blood

* Read before the Laboratory Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 21, 1927.

† The term "antigen" is used to designate the material used in the *in vitro* tests thus differentiating it from its strict usage to connote substances stimulating the production of antibodies in the animal body.

cultures and infected placentas by the method of Bass and Johns.⁹ The results indicate that a heavily infected placenta contains an unbelievably large concentration of plasmodia and yields a total amount of malarial protein far greater than can be obtained from cultures of peripheral blood.

The original method for preparing "antigens" from infected placentas which proved most satisfactory is as follows: The fresh placenta is minced in a meat chopper and added to an equal volume of ether. After extracting for several weeks in ether, the wet residue, i.e., ether insoluble portion, is added to an equal amount of Coca's extractive, consisting of an aqueous solution of 0.5 per cent sodium chloride, 0.05 per cent sodium bicarbonate and 0.4 per cent carbolic acid. After extracting for about one week the mixture is filtered through hard paper and the

however, half as much Coca's solution was added to the placental material, and the resulting mixture became quite acid. In consequence it was carefully adjusted to a pH of 7.8 before use. This stronger solution of proteins after adjustment of its pH was found to be more satisfactory.

The actual tests were made in small tubes about 4 x 50 mm. with a capacity of about 0.65 c.c. The patient's serum (.15 c.c.) was placed in the bottom of the tube and a like quantity of antigen layered on top. Positive reactions consisted of a "ring" of precipitate between the interplaces of the two liquids and appeared after an incubation of 1 hour at 37°C. and 6 hours sojourn at icebox temperatures. After some experience it was found satisfactory to limit the tests to two antigen dilutions—undiluted and 1-5. The final test consisted of four tubes as follows:

	Tube 1	Tube 2	Tube 3 (Control)	Tube 4 (Control)
	c.c.	c.c.	c.c.	c.c.
Patient's serum undiluted	0.15	0.15	0.15	0
Antigen	0.15 (undiluted)	0.15 (1-5)	0	0.15 (undiluted)
0.85 per cent NaCl	0	0	0.15	0.15

clear filtrate used as "antigen." The preliminary treatment with ether, possibly by increasing the permeability of the cell walls, was found to be quite necessary, but it is to be emphasized that only the ether insoluble portion was used in the preparation of the antigen. The resulting antigen was nearly neutral or slightly alkaline. In the second year's work,

Considering only the "antigens," prepared as described, we (Taliaferro, Taliaferro, and Fisher)⁸ tested 86 cases in 1926 and 64 cases (Taliaferro and Taliaferro)⁸ in 1927. The first series of tests consisted of serums from 54 infected persons, which gave 45 positive (10 +++, 21 ++, 14 +), 2 doubtful and 7 negative tests; and

TABLE I
PRECIPITIN RESULTS (86 CASES) WITH AN "ANTIGEN" PREPARED FROM A HEAVILY INFECTED (*P. falciparum*) PLACENTA, EXTRACTED IN ETHER AND THE ETHER INSOLUBLE PORTION DIGESTED IN COCA'S SOLUTION

Results of blood examination	Precipitin Results					Total number of cases omitting doubtful readings, giving:	
	+++	++	+	+	—	positive precipitin test	negative precipitin test
Positive in thin or thick films	10	23	14	2	7	45	7
Negative in thick film		2	4	1	25	6	25

TABLE II

PRECIPITIN RESULTS (64 CASES) WITH "ANTIGENS" PREPARED SIMILAR TO THAT IN TABLE I FROM HEAVILY INFECTED PLACENTAS (*P. falciparum*), BUT ADJUSTED TO PH 7.8

Results of blood examination	Precipitin Results					Total number of cases (omitting doubtful readings) giving:	
	+++	++	+	+	—	Positive precipitin tests	Negative precipitin tests
Positive in thin or thick films	4	11	15	1	1	30	1
Negative in thick films	none	none	1	4	27	1	27

from 32 persons negative for malaria which gave 6 positive (2 +++ , 4 ++), 1 doubtful and 25 negative tests. The second series contained serums from 32 infected persons which gave 30 positive tests (4 +++ , 11 ++ , 15 +), 1 doubtful, and 1 negative; and 32 persons negative for malaria which gave 1 positive, 4 doubtful and 27 negative tests. There were fewer cases tested in the second series because we spent considerable time making multiple tests on each person in order to ascertain the effect of treatment and how long a given serum could be stored and still give a positive test.

Space will not permit a discussion of these results in detail but they will be published with the final data. Similarly we shall not discuss other antigens that were tried except to mention the fact that a very reactive one was made by first mincing an infected placenta in a meat chopper, then concentrating the malarial plasmodia by Bass and John's⁹ technic and drying the material over calcium chloride. To prepare the "antigen" for use this powder was extracted in N/20 HCl for 18 hours and just

before use the supernatant liquid was neutralized with N 20 NaOH. This method presents so many technical difficulties (chief among which is that the malarial plasmodia cannot be concentrated unless the placenta happens to be passed when the parasites are full grown), that we have centered our attention on the easier method already outlined. Throughout our work *P. falciparum* "antigens" have reacted quite as well with *P. vivax* serums as with homologous serums.

Much more work needs to be done. Undoubtedly the greatest single drawback now is the difficulty of obtaining infected placentas because placental localization is infrequent even when the mother is infected with *P. falciparum*. One placenta, however, yields enough material for hundreds of cases and our next experiments will be directed toward ascertaining how long our "antigens" can be preserved and still remain active. We also hope that by improvement of technic the reactions can be made considerably stronger and that a larger proportion of +++ reactions can be obtained.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Two Studies of the Causes of Stillbirths—These studies include about 500 cases of stillbirths reported in hospitals or homes in the Bellevue-Yorkville District of New York City, and 18,634 cases from selected sections of the birth registration area of the United States. The percentages of deaths from each cause in the birth registration area in 1924 were: prolapse and compression of the cord 9.1, diseases of the placenta and membranes 8.9, difficult labor 8.6, abortion, miscarriage and premature birth 8.2, malpresentation 5.3, albuminuria and other diseases of pregnancy 5.2, asphyxia of child 4.1, malformation 4.1 and syphilis 2.6. In the Bellevue-Yorkville District asphyxia of the child caused 15.1 per cent of the deaths, abortion, miscarriage and premature birth 13.7, diseases of the placenta and membranes 8.1, difficult labor 7.0, prolapse and compression of cord 6.8, toxemia and nephritis 6.7, malformations 3.0, syphilis 2.8, and malpresentation 1.2 per cent.

Analysis of 498 cases in the Bellevue-Yorkville District shows that 56 occurred at home and 442 in institutions. The relative frequency of hospital or institutional cases and at-home cases was about equal for asphyxia of the child, difficult labor, and death in uterus. Abortion, miscarriage and premature births were more than twice as frequent among hospital cases as among home cases. Diseases of the placenta and membranes are considerably greater, while prolapse and compression of the cord, toxemia and nephritis are but slightly higher among hospital cases. All stillbirths due to diseases of the

child, rupture of the uterus, hemorrhages, hydramnios, therapeutic induction of labor, inertia of uterus and extra-uterine pregnancy occurred among hospital cases. Malformations, syphilis, and injury to the child are greater among home cases. Other diseases of the mother such as influenza, high blood-pressure, traumatism and overwork are also greater in home patients. The causes due to conditions of the mother cover 202 stillbirths, those due to conditions of the child were 188 while 108 were due to conditions of mother and child.—Laura W. Nathan and Godias J. Drolet. *New York State J. Med.* 28:78-80 (Jan. 15), 1928.

New Haven's Health Record, 1927—In general, New Haven's 1927 record is favorable. This is shown by a lowered death rate from all causes (11.2 per 1,000 population), and by decreased sickness and deaths from certain communicable diseases. That no deaths occurred from typhoid fever, measles and whooping cough is indeed noteworthy. There were no cases of small-pox either in the city or the state. Despite a rise in diphtheria in different sections of the country the incidence of this disease remained low in this city, there being only 3 deaths attributed to this cause, a rate of 1.6.

In 1927, 4,457 children were immunized against diphtheria, so that now over 75 per cent of the school children and 25 per cent or more of the preschool children are known to be protected from this dreaded disease.

The infant mortality rate in 1927 was 54 per 1,000 live births. A steady

decline has taken place in the tuberculosis death rate, from 57 in 1926 to 49.2 in 1927.—New Haven Department of Health. *Monthly Bull.* 55:3-4 (Jan.), 1928.

Public Health in the District of Columbia—Infant and maternal mortality in the nation's capitol have been studied by the U. S. Children's Bureau. In its weekly news bulletin for March 17, 1928, the bureau gives the following facts:

A study of the vital statistics of the District showed that from 1915 to 1926, inclusive, there has been a very appreciable decrease in the infant mortality rate among both colored and white infants. Tentative figures for 1927, furnished by the Bureau of Vital Statistics of the District Department of Health, appear to indicate the continuance of this decrease, the total infant mortality rate for 1927 being 65.7 deaths per 1,000 live births, the white rate being 47.5 and the colored 107.4. A comparison of the average rate for the three years 1924-1926 in the District, however, with the average rate for the birth-registration area as a whole and with other cities in the area having, like Washington, 2,000 or more colored live births annually, shows that the rate in the District (82.7) during the period was higher than that of the birth registration area (71.9) or of any other city of the group except Baltimore, the difference being due mainly to the comparatively high colored infant death rate in the District.

With regard to maternal mortality, the average rate for the years 1924-1926 was much higher in the District of Columbia (9.6) than in the birth registration area as a whole (6.5) or in any other city of the group mentioned. The average white maternal mortality rate in the District of Columbia was 1.4 points higher and the average colored maternal mortality rate 4.9 points higher than that in Baltimore, which more closely resembles Washington than any other city of the group.

Infectious and Contagious Diseases Reported in Kansas in 1927—During 1927, 41,888 cases of the major acute infectious diseases were reported to the State Board of Health, an increase of 10,972 cases over the number reported for 1926. Twenty-five hundred

and thirty-one deaths were reported, a decrease of 627 in 1926. Fewer deaths from whooping cough, tuberculosis, pneumonia and influenza account for the marked decrease, although there was an increase over the year 1926 in the number of deaths from scarlet fever, diphtheria and infantile paralysis.

Nineteen thousand five hundred and seventy-five cases of measles were reported with 83 deaths, 22,464 cases and 275 deaths were reported in 1917 and 20,263 cases with 129 deaths in 1924. New low death rates were established in three diseases. The death rate from typhoid fever was 3.5 per 100,000 population, only 66 deaths being reported. The previous low rate was 4.0 in 1924. There were 645 deaths from tuberculosis, and the rate was 35.1. There were 931 deaths from pneumonia, the second lowest number on record, and the rate was 50.6. Approximately 800 fewer cases of pneumonia and 138 fewer deaths were reported in 1927, than during 1926. Scarlet fever cases showed an increase of approximately 2,000 over 1926, and more than twice as many deaths. The total number of scarlet fever cases is only exceeded by 1921, when 6,535 cases were reported. Whooping cough showed a decrease of nearly 1,200 cases from the previous year. The disease was less fatal as 1.8 per cent of reported cases died, as compared with 2.6 per cent mortality during 1926.

Thirteen hundred and ninety-three cases of smallpox and one death—that of an infant less than one month of age—were recorded in 1927 as compared with 535 cases and two deaths in 1926. One thousand and seventy-two cases of diphtheria and 75 deaths were reported, as compared with 903 cases and 49 deaths in 1926. Diphtheria was much more virulent in the past year as 6.9 per cent of reported cases died, as compared with 5.4 per cent case fatality in 1926. No deaths occurred during 1926, in children who had been immunized with

toxin-antitoxin. Five hundred and twenty-six deaths were caused by influenza, as compared with 903 the previous year. One hundred and ninety-six cases of infantile paralysis were reported, which ties the previous high number reported in 1910. Forty-nine cases, or 25 per cent, resulted fatally, as compared with 53 deaths, or 27 per cent fatality in 1910. A review of the statistics over a 10-year period shows in children under 5 years of age: whooping cough, 93.6 per cent mortality (55.7 per cent under 1 year), measles, 52.9 per cent mortality, diphtheria 49.6 per cent mortality and scarlet fever, 36.9 per cent mortality.—Kansas State Board of Health. *Morbidity Rep.*, Mar. 10, 1928, pp. 1-2.

1927 A Good Health Year in Illinois—It appears from preliminary statistics that 1927 was one of the healthiest years Illinois has ever enjoyed. A 21 per cent decline in the continued prevalence of typhoid fever, scarlet fever and pneumonia accounted for a substantial decrease below the 1926 mortality from these infections. These data indicate a general mortality rate in the state for 1927 of slightly more than 11 per 1,000 population.

The predominating cause of the favorable mortality rate was the pronounced decline and unusually low prevalence of pneumonia. This highly fatal disorder dropped from 17,629 reported cases in 1926 to 13,202 in 1927, a figure substantially lower than any previous annual record since 1921. Influenza likewise fell off from 4,566 to 1,828 cases. Another particular source of improve-

ment was an apparent drop in the mortality from tuberculosis. Case reports decreased by 2,375. There were only 2,919 deaths from tuberculosis during the first 6 months of 1927 as against 3,013 during the corresponding half of 1926 and 2,986 in the first half of 1925. Scarlet fever prevalence declined from 16,997 cases in 1926 to 14,622 in 1927. This indicates a reduction of 25 or 30 deaths from that cause.

Measles soared to a point higher than in any previous year since 1923, notifications reaching 41,012 cases. This figure probably expresses about one-half of the actual number of cases. Since mortality ordinarily runs to about 1 per cent of the reported cases per year, it appears that the increase in deaths from measles amounted to about 100 in 1927. Diphtheria also ended the downward trend that has marked the course of that disease for several years, increasing from 4,529 cases in 1926 to 6,272. Smallpox incidence rose from 1,098 to 1,247. Fortunately, the disease has been mild so that the relatively large incidence in Illinois did not seriously influence mortality. Perhaps the most disconcerting factor in the year's health conditions was the sharp rise in the prevalence of infantile paralysis. Notifications numbered 483 against 121 for the year before and made 1927 the worst year for that infection since 1921. Reports of venereal diseases brought the annual notifications of those diseases to a new high level in 1927. A total of 35,278 fresh cases were reported, an increase of 6 per cent above the 1926 record.—*Illinois Health News*, 14:35-6 (Feb.), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C.E.

Estimation of Lighting in Schools—Lighting Birmingham schools was studied by comparing the illumination received on a screen in a given position with the illumination received from the whole hemisphere of the sky. The ratio was obtained by referring each reading to the illumination from a standard lamp. The instrument for this purpose is called a luxometer hand photometer. A coefficient of .01 indicates that the light received at a given point is equal to one-hundredth part of the light available from the total sky.

Readings were made near the middle and at the worst lighted parts of the room. Average readings varied from coefficients .0014 to .02 and "worst" readings from .00043 to .0077. Standards were suggested for good, fair, poor and bad lighting, i.e., good lighting being indicated by coefficients of .02 (or above) to .007 in the middle of the room, and coefficients of .007 (or above) to .003 at the worst lighted points. *Med. Off.*, 37:285 (June 18), 1927. Abstr. C. L. Pool.

Methods for Differentiation of Bacilli of Coli-Aerogenes Group, Applied in Shanghai—The collection made of the coli-aerogenes group included the following strains: 100 from human, 50 from animals, and 50 from soil. The tests applied were: Methyl red, Voges-Proskauer, Koser's citrate, and indol production. Before each test the respective media were incubated for 5 days at 37°C.

Very little difference was noted between the fecal strains from human and animal sources. With the citrate test, 92.7 per cent of the human-animal

strains failed to grow, while only 20 per cent of the soil strains failed. Indol was produced by 91.3 per cent of the strains from fecal sources and by 32 per cent of those from the soil. With the methyl red, Voges-Proskauer tests, 95.3 per cent of the fecal strains and 76 per cent of the soil strains were M.R.+ and V.P.—. From this the author concludes in part that the citrate and indol tests are of value, the citrate being the better of the two, and that the methyl red and Voges-Proskauer tests are of no value.

Inasmuch as the soil samples were collected chiefly from railway embankments, rifle ranges and the tops of grave mounds, it is possible that some fecal strains may have been present in the soil. E. P. Hicks. *J. Hyg.*, 26:357 (Aug.), 1927. Abstr. C. T. Butterfield.

Aeration of Water—An apparatus, consisting principally of 3 aspirator bottles and an aeration chamber made of the outer jacket of a Liebig condenser arranged to determine the amount of oxygen that is dissolved from surface streaming and from air bubbles passing through the liquid in the condenser is described. When water containing about 1.0 p.p.m. of dissolved oxygen was allowed to stand in the condenser with only a small tube open to the air the oxygen content was increased to 1.2 p.p.m. in 24 hours. When the condenser was not quite full, leaving an area of water equal to the cross section of the condenser exposed, the solution of oxygen from the streaming effect was increased to 5.0 p.p.m. after standing an additional 24 hours. However, when air was slowly bubbled through the water in the condenser for only 10 minutes the oxygen content was

increased from 1.0 to 5.0 p.p.m. The authors present this experiment to controvert the opinion that probably only a very minute quantity of oxygen is absorbed by sewage as air passes through it and that most of the aeration takes place at the surface. Gilbert J. Fowler and S. N. Chatterjee. *Surveyor*, 72:139 (Aug. 12), 1927. Abstr. C. C. Ruchhoft.

Holborn and St. Pancras Town Planning Scheme—This article covers some of the recommendations made in a planning scheme for 2 areas having a total of 208 acres. Height of buildings is limited to $1\frac{1}{4}$ times the width of the street, no building to extend beyond a line drawn at an angle of 51° with the horizontal from the opposite side of the street. Buildings used for dwellings shall not cover more than $\frac{2}{3}$ of the plot; where the upper floors of the building are used for residence, the ground floor shall not cover more than $\frac{9}{10}$ and the upper floors $\frac{2}{3}$ of the plot. Business premises shall not cover more than $\frac{9}{16}$.

Nineteen and one-half acres—between 9 and 10 per cent of the areas—are reserved for garden squares. *Surveyor*, 72:358 (Oct. 21), 1927. Abstr. R. E. Tarbett.

Effect of Different Kinds of Pipe On Quality of Water Supplies—Investigations have shown that no matter what kind of pipe is used the water will take into solution a part of the metal, the amount depending somewhat on the water and the quality of pipe.

Iron pipe is affected the most except when galvanized. Tin lined pipes are the least affected. Much zinc is taken into solution from galvanized iron pipe and brass pipe, which also yields a small amount of copper. From copper pipes only a small amount of copper is taken but any zinc present is readily dissolved. Lead pipes have long been known to

yield lead and for this reason are dangerous as 0.04 parts per 100,000 in solution will cause lead poisoning of some people when habitually used. Some doubt exists in the minds of different authorities as to the effect of copper and zinc on the human system.

As a matter of precaution it is suggested that where such dangers as the above exist that the pipes be flushed thoroughly each morning before using the water. A small amount of copper is always present in the human system, coming from water and certain foods. H. W. Clark. *J. New Eng. W. W. Assn.* 41:31 (Mar.), 1927. Abstr. H. D. Cashmore.

Forecasting and Control of Cholera Epidemics in India—This article covers a study of the cholera incidence in the various sections of India and its relation to the climatic conditions, particularly the relation to the rainfall during the previous monsoon and the ensuing winter months. The author found that a deficient rainfall was one of the most important factors in predisposing to cholera epidemics.

Pilgrimages constitute a great factor in the spread of cholera in India, but it was found that this spread was not as great during those years when there was an excess of rain during the previous monsoon as when rainfall was deficient.

By means of the meteorological records, it is possible to be forewarned several months in advance of the danger of an increase in cholera and allow for control measures to be taken particularly with reference to pilgrimages.

The efficacy of anti-cholera inoculation has been demonstrated and the author recommends the inoculation of all pilgrims before starting on their journey to those places where there is more or less danger of contracting cholera. Leonard Rogers. *J. Roy. Army Med. Corps*, 49:261 (Oct.), 1927. Abstr. R. E. Tarbett.

Wet Sludge as Fertilizer—

The fertilizer value of wet sludge, 95 per cent moisture, from the Bedford, England, sewage treatment plant is 87 per cent greater than similar sludge air dried, 28 per cent moisture, as determined by actual experiments. The elevation of the sludge outlet valves at the plant are above the surrounding land so that it is possible to discharge the wet sludge on the land by gravity. The advantages claimed by this method of sludge disposal are: (1) Sludge is never so valuable for fertilization as when fresh; (2) it can be more evenly distributed; (3) fresh sludge warms cold soils, makes them more porous, and the fermentations that take place during decay tend to make the soil more mellow; (4) the plant food is more available; (5) when spread evenly and thinly, there is no loss of its valuable constituents through early fermentation; (6) the crop is more even; (7) it improves the mechanical condition and drainage of the soil; (8) it is disposed of with advantage at a low cost. S. Duxbury, *Pub. Works*, 58:374 (Oct.), 1927. Abstr. R. J. Faust.

Operating Results of the Essen Activated Sludge Plant—The activated sludge plant at Essen-Rellinghausen has been in operation since December, 1925, serves 45,000 people, and receives a dry weather flow approximating 130 gallons per capita per day. The wooden paddles (mechanical agitation device) used in conjunction with compressed air have continued to show their usefulness. With a $3\frac{1}{2}$ hour aeration period the air consumption is only 0.08 cu. ft. per gallon, and the entire power consumption is 7 h.p. per m.g.

The analytical results, which are comprehensively stated in a table, show a reduction in suspended solids of from 180 p.p.m. in raw sewage, and 120 p.p.m. in Imhoff tank effluent, to 6 p.p.m. in effluent from the activated

sludge plant. Consumed oxygen is shown as 532 p.p.m. in raw sewage, 350 p.p.m. in Imhoff tank effluent and 30 p.p.m. in effluent from the activated sludge plant. The hydrogen ion concentration remained relatively the same for raw sewage, Imhoff tank effluent and effluent from the activated sludge plant, being expressed as pH 7.5 for both raw sewage and tank effluent and 7.2 for activated sludge plant effluent.

Heating is accomplished by raising the temperature of water from the pressure supply mains, in a boiler heated by sludge gas, to 70 or 80°C., and then introducing it into the bottom of the digestion tank. This obviates the difficulties experienced where heating coils are passed through the sludge. The temperature in the sludge tank, which prior to heating was 8° to 9°C., has since been maintained at 21°C., with a tenfold increase in gas production and consequent increased digestion tank efficiency. Only that gas generated in the digestion tank is used in this way. Gas from the Imhoff tanks is sold to the municipal gas works. Since heating has been introduced the total gas production has been increased, the CO₂ content of the gas has increased somewhat, and the methane content remains over 73 per cent.

The constructions cost, exclusive of preliminary clarification units, is now \$90,000, with an operating cost of \$12,500 per annum. Karl Imhoff. (Trans. from German by Gordon M. Fair). *Eng. News-Rec.* 99:790 (Nov. 17), 1927. Abstr. C. H. Kibbey.

Sink Hole Topography Study for Sewage Disposal—A proposal by the city of Alton, Ill., to dispose of sewage from a rapidly growing sub-division into a sink hole resulted in a study by the Illinois Geological Survey and the Illinois Department of Health. The question raised was whether the sewage thus disposed would enter the Mississippi

River directly above the Alton water works intake. The study disclosed that it would.

Fluorescein was introduced into the stream entering the sink hole and by the following morning green color persisted for two hundred feet in the Mississippi River below the mouth of the subterranean channel.

The article describes in detail the geology of the area. J. E. Lamar. *Eng. News-Rec.* 99:642 (Oct. 20), 1927. Abstr. A. H. Wieters.

Sanitary Problems in a Colliery District—Colliery towns are usually built in narrow ravines where there is barely room for river, railroad and highway. The stream is polluted with coal washings and surface wash from the villages. The water supply frequently obtained from surface sources is often contaminated.

Subsidence due to mining operations damages the houses so that many are made uninhabitable. Pneumonia rate is higher due to returning to homes in damp, perspiration-soaked clothes. Pit head baths should be provided. Smoke abatement measures should be instituted. The sanitary problems in general are peculiar to collieries. W. A. Murphy. *J. State Med.* 35:545 (Sept.), 1927. Abstr. L. M. Fisher.

Investigation of Recirculation and Treatment of Waste Waters from Process of Paper Making—Pollution of streams in New Jersey by paper mill wastes has been a serious problem for the past decade. No type treatment in the state has been entirely successful. Mill owners objected to the recirculation and reuse of water (closed system) for it soured and slime was produced hindering the process of paper making.

The mill investigated and reported on, had 4 paper making machines. All waste white water was being reused.

Two recirculating systems were operated. One used chemical precipitation of wastes and this water was used for felt showers with make-up waste rates of 3 to 1. Other system returned waste white water direct from pits to breakers or beaters. Chemical precipitation plant handles all water over and above that used by breakers or beaters. "Boothall," a balanced coagulant is used. Reclaimed stock from precipitation plant makes up 20 per cent of the material used by No. 1 machine; that is, 15 tons of finished material is procured from 12 tons of old newspaper stock (raw material).

After the investigation was made it was reported that all waste white water was being used and that for long periods it was unnecessary to pollute the creek with this waste. I. R. Riker. *Pub. Health News*, N. J. Dept. of Health, 12:290 (Sept. Oct.), 1927. Abstr. G. H. Hazlehurst.

Treatment of Municipal Offal by Fermentation in Closed Cells—The Becarri system is used in many Italian cities—Florence, Naples, Bologna, Carrara, Nowarra—for treating stable manure. The plant consists of closed chambers of about 5 cubic meters capacity, in which the manure undergoes fermentation for about 60 days. Of the evolved gases, ammonia, being the greatest, is recovered in absorption towers by means of iron sulphate and phosphate of lime. The temperature rises to from 70 to 75°C. by this method of fermentation. Nitrogen losses are also reduced to a minimum. Similar treatment of municipal organic wastes requires only 40 days. A disadvantage of treating this latter material in this way is that approximately 50 per cent of it is not fermentable. Jean Bordan. *Ann. d'hyg. publ. industr. et soc.* 5:142, 1927; Trans. of an abstract by Kammann in *Zentralbl. f. d. ges. Hyg.*, 15:496 (Aug. 10), 1927. Abstr. J. K. Hoskins.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH.D

Treatment of Burns by Tannic Acid—The author has used the tannic acid treatment of burns, first advocated by Davidson of the Henry Ford Hospital (*Surg. Gynec. and Obstr.*, xii. 202, 1925) in 1925. Aqueous solutions, in a strength of about 2 per cent applied to a burned surface for 24-48 hours produce a coagulum containing degenerated and broken-down tissues. The surface is actually tanned. As the absorption of the toxins is prevented by precipitation, the toxemia does not develop. Thus the constitutional reaction following the burn is modified. (It has been shown that if the blood supplied to the burned area is cut off, the body reaction does not take place. Vogt, by performing parabiosis between 2 animals and burning one, found that both were equally affected, though not so severely as under ordinary circumstances.) The author describes the application of this method to a girl baby aged 2 years, suffering from severe shock and with vesication over the whole scalp, the brow, and down in front of both ears to the neck, the whole of the neck posteriorly, the left shoulder, and the flexor surface of the left elbow joint. A dirty rag dipped in olive oil had served as a dressing and the child was convalescing from an attack of bronchitis. The skin was cleansed with ether soap, loose tissues removed, then swabbed with absolute alcohol. Strips of gauze dipped in a freshly prepared 2 per cent solution of tannic acid were laid over the surface. The whole was then bound loosely in large bandages. A light anaesthetic of ether and oxygen was used for 10 minutes. The dressing was kept moist by sprinkling it frequently with a solution.

A special cage was devised to take the weight of the head and shoulders off of the parts while resting. By the seventh day the coagulum was quite loose on the underlying surface. This was removed on the eighth day exposing a clean healing surface beneath. On the ninth day the child developed bronchial pneumonia but the wound remained clean and the child was up 10 days' later. "There is now a growth of fine fluffy hair over about two-thirds of the surface of the scalp."—R. M. Gordon, *Lancet*, 5451:336 (Feb. 18), 1928. [See also same Journal, page 351, an editorial comment on another case due to a gasoline explosion which emphasizes the immediate relief from pain and lessening of discharge by using 2½ per cent tannic acid.]

The Heating of Buildings—The most popular method in the heating of buildings is that of radiation from coal fires, gas fires, or electric radiators, whose supporters claim that this method is pleasant and exhilarating because the rays do not warm the air through which they pass so much as the objects on which they impinge. The introduction of warm air by the plenum system reverses the process. A new method of radiant heating has been introduced in which large surfaces or panels in the ceiling, walls, or floors, are warmed by concealed coils of hot water pipes, but the radiation so obtained is some 1,400 times less than that from a fire at about 2,000° F. so that "radiant heating" of this type is somewhat misleading. However the Industrial Fatigue Research Board found that in panel heating there was an even distribution of heat over

the room so that temperatures did not vary by more than 2° F. while radiators and plenum systems may vary as much as 10° to 20° between floor and ceiling. Direct panel radiation is said not to have caused any definite subjective effect, such as experienced when gas or coal is used, while rooms heated by fires felt comfortable when 7° cooler than convection-heated rooms, the permissible reduction of air temperature in panel heated rooms was less than 1°. Panel heating, without claiming comparison with the sun's rays, is held to have a great future, and it may come to replace hot water radiators and plenum air installations. "In big rooms, however, any system of radiant heating ought to be supplemented by small hot-water radiators before each large window, so that down-drafts of cold air may be counteracted."—*Lancet*, No. 5454:511 (Mar. 10), 1928.

A Physiological Study of Ventilation and Heating in Certain Factories—Among the practical conclusions deduced in this 82 page report are the following: (1) We are thoroughly in favor of employing natural systems of ventilation as against artificial ones, but we realize that it may frequently be impossible to avoid artificial aids entirely; (2) local exhaust ventilation for the removal of dust and fumes may be essential; (3) cross window ventilation is often insufficient especially in winter time when most of the windows are kept shut, so some form of exhaust is necessary, and may require mechanical assistance; (4) the extraction of the air should never, under ordinary circumstances, be at floor level, since this increases the amount of air movement around the feet; (5) such exhausts should be located about 7 or 8 feet above the floor instead of 10 feet so as to increase the air movement about the head level; (6) certain shapes of factory

rooms such as large square rooms require special solution; (7) too much stress cannot be made on the principle of placing the source of heat as near the floor as possible; (8) the hot air or radiators should be kept at a relatively low temperature, for the hotter the air the more quickly will it rise to the roof—overhead steam pipes are the worst offenders but overhead plenum installations are likewise bad since they may induce temperature differences amounting to 11°-21° between the floor and ceiling level; (9) the amount of energy wasted by overheating the upper strata of air in factories must be enormous; (10) heating units installed near the floor caused very low temperature gradients, while those under the floor gave an even temperature at all levels. "Therefore we think it very desirable that heating engineers should attempt the introduction of floor heating systems wherever they consider them practicable," and (11) natural ventilation is not only less expensive than artificial systems, but more pleasant, more healthful and creates a greater sensation of freshness. "There is some *prima facie* evidence that the health of the workers is influenced by moderate differences in the atmospheric conditions under which they are working. At one factory, the time lost from sickness was determined for 809 women over a period of 2 years, and in a workroom where the mean temperature was 7° F. above the average for the whole factory (owing to the presence of drying stoves) the sickness was 32 per cent in excess, while in another room where (in winter) it was 7° below the average, it was 21 per cent in excess. At another factory, 2 groups of women were engaged on the same occupation in different rooms, in one of which the mean air velocity was only half as great as in the other. The women in this room were found, over a 2-year period, to have 53 per cent more sick-

ness than the others.”—H. M. Vernon, T. Bedford, and C. G. Warner, Industrial Fatigue Research Board, Great Britain, London W.C.2. *Report No. 35*, 1926.

Carbon Monoxide Poisoning—The first of these bulletins evidently printed by the Carnegie Steel Company was issued in October, 1922, and reviews the specific literature and findings on carbon monoxide poisoning with the addition of the author's own observations. In regard to treatment the author prefers the mechanical method, using the pulmotor. “In over 100 very severe cases, this apparatus was used and excellent results obtained, with no noticeable after effects. It furnishes a mixture containing over 37 per cent oxygen, and owing to its mechanism supplies the lungs with a greater volume of this mixture than is possible by any of the manual means, thus ventilating the lungs regardless of the lessened amount of CO_2 in the blood, and also regardless of whether the patient is breathing or not. The pressure feature is a good one, and I believe, due to this pressure, the blood plasma will take up Oxygen and carry it to the tissues independently of the corpuscles.” . . . “It is essential that the pulmotor or the manual method be continued for at least 2 hours before hope of resuscitating the patient is given up.” The author has never seen any serious after effects of gas poisoning, although some of his patients were unconscious for several hours and 1 case for 3 days. “Several patients complained of muscular pains and headache lasting a few days; 2 patients were partially demented for several days, and another for 2 weeks, but in all these cases they made an uneventful recovery.”

The second bulletin dated, January, 1928, of 39 pages, also entitled “Carbon Monoxide Poisoning,” appears to include the material of the first bulletin

with the addition of much new material largely from the literature, but in the last few pages summarizing his own experiences. He again states that after 18 years' experience in the treatment of several hundred cases of gas poisoning using the pulmotor he has found the criticisms of it unfounded, while in such cases as those having broken ribs, burns, lacerations, etc., the Shafer Prone Pressure Method would cause further damage. The author believes that exposure to low concentrations over long periods of time results in mental sluggishness with deficiency of muscular power and such symptoms as indigestion, loss of memory, loss of sexual desire, headaches, tired out feeling, loss of appetite, and nausea. Yet, the author has talked with a number of men who have been exposed daily for years, and who exhibited no symptoms whatever. He has never seen anemia, nor optic disturbances in chronic poisoning. He considers that the blood will have to be saturated from 50 to 55 per cent before there will be a deficient oxygen supply to the tissues. In over 2,000 cases, in all degrees of severity, he has seen but few serious after effects and knows of only 1 case in which the patient has been demented for several years following severe gassing. He has never seen a single case of pneumonia develop following carbon monoxide poisoning and suggests that when the same occurs it is not due to carbon monoxide but to the fact that the patient is unconscious so that saliva and foreign material gets into the respiratory tract causing an irritation. Thus it is impossible for pneumonia to develop in mild cases where the patient is not unconscious. Deferred fatal results may occur in heart disease victims. Such result may take place from 3 hours to 3 or 4 days following the gassing, “but during this time the patient is markedly short of breath and fighting for air continuously, especially on the least physical effort.

I do not believe it possible for a patient to be gassed and completely recover and then develop some condition months afterwards. If any damage has been done, sufficient to cause any symptoms, these symptoms will persist until nature has cured them and after that there will be no re-occurrence."

(The *abstractor* considers the author's vast experience of great importance but regrets that the author has never published the details of his cases so that others might study them.)—Frank S. Rossiter. Carnegie Steel Company, Pittsburgh, Pa., Jan. 1928.

Visualization of Industrial Hygiene By Models—In an attempt to combat the carbon monoxide hazard in public garages the bureau of industrial hygiene illustrates a garage equipped with suction fans, beneath gratings in the floor where automobiles stand, which will change the air completely in from 3 to 5 minutes. Intakes are also provided to equalize the out-take. (Illustration accompanies article.) This arrangement

dilutes the CO content so as to make the hazard negligible.—*Ind. Hyg. Bull.*, N. Y. State Labor Dept., Dec., 1927.

Phosphorus Poisoning and Compensation—Compensation for phosphorus poisoning contracted during the course of employment has been denied under the Virginia law in *Turner v. Virginia Fireworks Co.*, 141 S. E. 142. In this case it was agreed that the employee had to handle white phosphorus and that in rubbing an aching tooth, she conveyed the poison to her mouth. This circumstance, was however, held not to have been an accident within the meaning of the workmen's compensation act of the state. This is a peculiar decision, to say the least, especially since a Maryland decision of 1925, *Victory Sparkler and Specialty Co. v. Francks*, 128 Atl. 635, held exactly the opposite.

A comprehensive article entitled "Workmen's Compensation and the Conflict of Laws," by Ralph H. Dwan appears in the *Monthly Labor Review* of the U. S. Dept. of Labor, Mar., 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Growth on a Synthetic Ration Containing Small Amounts of Sodium—Previous investigations having shown that certain amounts of sodium or potassium or both are essential in the diet, an investigation was conducted to find the amount of sodium required in a synthetic ration. The diet mixture contained casein, yeast, agar, lard, cod liver oil (rich in vitamin A), starch and salt mixture, sodium carbonate being eliminated from the ration. The carbonates of calcium, magnesium and potassium, as well as citric acid were

added in powder form. To this basic ration varying amounts of sodium bicarbonate were added. Rats fed on rations containing sodium varying from 0.02 to 0.5 per cent failed to maintain successful growth when the sodium was 0.30 per cent or less. Differences in growth periods are shown for animals on a ration containing 0.2 and 0.3 per cent sodium, and the physical condition of the animals also is marked in the growth curves. The animals receiving smaller amounts of sodium were seriously affected. There was no reproduction on

any of the vitamins used. Vitamins A, B, and D were adequate so that poor growth is not attributed to vitamin deficiency. Immediate improvement resulted when the stock rations were restored.—J. L. St. John, *J. Biol. Chem.* 77:27 (Apr.), 1928.

The Vitamin Content of Mung Bean Sprouts—Mung bean sprouts constitute a considerable portion of the diet in the oriental population of Honolulu, these sprouts selling for 5 cents a pound. They are produced from green mung beans, the nutritive value of which has been studied and reported (*A. J. P. H.* Jan., 1928, p. 114), and are shipped directly from China. Great care is taken in the sprouting of these beans to produce a clean white product with very little chlorophyll formation. A résumé is given of work previously done on the vitamin content of bean sprouts as regards A, B, and C, and tables are included showing the composition of the mung beans and fresh sprouts. In the investigation reported the bean sprouts were cooked by steaming for varying periods from 2 to 8 minutes. In determining vitamin A, basal diet of meat residue, starch, yeast, salt mixture, sodium chloride and Crisco were used and the meat residue was treated for extraction of casein and the whole mixture exposed to bright sunlight to insure the presence of vitamin D. Both raw and cooked bean sprouts were fed. Four gm. of raw and 4 gm. of cooked sprouts produced gains approximating 3 gm. Bean sprouts are a fair source of vitamin A compared to some other vegetables; according to Sherman's evaluation they have 110 to 120 units per lb. as against 750 to 3000 units per lb. for lettuce and 2500 to 3500 units for green peas. In determining vitamin B it was found that in rats weighing 46 to 59 gm. and 28 or 29 days old, 3 gm. of raw sprouts produced perfect results. Animals were found to be the same weight at the end

of 8 weeks as at the beginning of the experiments. It was concluded that the amount of raw sprouts in the daily ration supplying vitamin B and maintaining weight is between 2.5 and 3 gm., and 2.2 and 2.7 for the cooked. The latter weights are equivalent to those given for the raw, there being little loss of vitamin B in cooking. Compared with other vegetables on Sherman's basis, bean sprouts show 150 to 180 units per lb. as against 150 to 200 for lettuce, 120 to 140 for carrots and 1000 for raw peas. Guinea pigs were used to determine the vitamin C content, being placed on Sherman's vitamin-C-free diet plus fresh alfalfa. Two gm. of raw sprouts were found to be insufficient to prevent scurvy. Of 4 guinea pigs fed 2.7 gm. cooked bean sprouts (equivalent to 3 gm. raw) two showed no sign of scurvy and two slight scurvy. It is concluded that the protective dose of bean sprouts so far as vitamin C is concerned lies between 3 and 4 gm., there being considerable destruction of vitamin C even in 5 minutes steaming. On Sherman's comparative basis, lemon juice, orange juice and tomatoes will equal 150 to 300 units per lb. Cooked bean sprouts have approximately 150 units per lb., or a trifle less.—Carey D. Miller and Doris B. Hair, *J. Home Econ.*, 20:263 (Apr.), 1928.

Chemical Sterilization of Milk Bottles in Relation to Tubercle Bacilli—The work recorded here was undertaken for the purpose of determining the efficiency of certain chemicals in sterilizing milk bottles infected with tubercle bacilli. Bottled milk is served to inmates of state institutions of Minnesota, many of whom are tuberculous and who drink the milk directly from the bottles by means of straws, providing a possible avenue of introduction of tubercle bacilli into the bottles before return to the dairy. Three series of experiments were conducted. In the

first experiment, milk was infected with sputum containing active tubercle bacilli, and to some of the milk was added calcium hypochlorite solution containing 10 p.p.m. available chlorine. One-half c.c. of this was placed at the bottom of clean milk bottles. Three concentrates of calcium hypochlorite solution was used, 10, 20 and 30 p.p.m. available chlorine. The contents were thoroughly agitated and centrifugalized, and two guinea pigs were inoculated from samples of each lot. One pig from each lot was chloroformed and autopsied 17 days after inoculation and its mate 23 days after inoculation. Every pig showed extensive tubercular lesions with abscesses at inoculation sites. The second series was made using chloramine (prepared by the action of ammonium chloride on calcium hypochlorite in solution) in dilutions of approximately 10, 30 and 100 p.p.m. available chlorine. The chlorine content was determined by titration. Control tests, using two pigs for each, were made with sputum treated with each dilution of the neutralized chloramine solution. All control pigs showed lesions of tuberculosis when autopsied 30 days after inoculation. These pigs showed abscesses at inoculation sites. The remaining pigs were autopsied 50 days after inoculation and showed all organs normal with increase in weight. These tests indicated that the lowest strength of chloramine effective is 95 p.p.m. for a period of 3 minutes. In the third experiment $\frac{1}{2}$ pint bottles instead of pint bottles were employed. The disinfecting solution entirely filled the bottle. These tests were for the purpose of comparing calcium hypochlorite in dilutions of approximately 50 p.p.m. available chlorine for 1 to 3 minutes, and both calcium hypochlorite and chloramine in dilutions of from 100 to 500 p.p.m. for periods of $\frac{1}{2}$ to 3 minutes. The chlorine solution deteriorated rapidly. The actual chloramine strengths determined by re-titration are indicated in tables. The control

pig showed lesions of tuberculosis when autopsied 31 days following inoculation. The remaining pigs were chloroformed and autopsied at the end of 2 months and showed no tuberculosis and had increased in weight. This test checks closely with series II, indicating that a strength of chloramine of approximately 100 p.p.m. available chlorine for 3 minutes is effective in killing tubercle bacilli and that in all of the experiments calcium hypochlorite was unsuccessful in destroying these organisms.—E. M. Wade, R. W. Archibald and H. A. Whitaker, *J. Bact.*, 15:189 (Mar.), 1928.

The Manganese Content of Raw and Cooked Vegetables—Similar work has been previously reported (*A. J. P. H.* Dec., 1927, p. 1288) on the manganese content of different plants and vegetables and the experiments herein reported were to determine the effect of cooking on the manganese content. Ten vegetables were analyzed to determine their manganese content. Both cooked and uncooked spinach, string beans, and beets are high in manganese while rutabaga, cabbage and onions have small amounts. The stalks and leaves were found to have a higher content than the roots, tubers and bulbs. Tables are given showing the loss of manganese in cooking and the manganese content of uncooked and cooked vegetables. Losses were found to be slightly greater for leaves than for roots, tubers and bulbs. An average loss of 20 per cent was noted when vegetables were boiled in a moderate amount of water, while there was a loss of 40 per cent when boiled in excess water. A loss of 12 per cent was noted in steamed vegetables and in pressure cooked vegetables, 22 per cent. Hence, steaming was found to be the most effective method for conserving the manganese content of vegetables while boiling in excess water the least efficient.—Stella Munger and W. H. Peterson, *J. Home Econ.*, 20:194 (Mar.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

Health Teaching—The teaching of health in the school system is now quite generally accepted after years of discussion pro and con. Health teaching in the hospitals is at present in the growing stage, being accepted by some and rejected by others. Miss Murphy, who apparently feels that education should reach all groups, outlines the various possibilities of public health instruction as afforded by groups in a children's hospital.

First, there is the child who is hospitalized for an indefinite period of time, a chronic or semi-chronic illness. The institution, with its provision of proper food for the patient, can in addition directly or indirectly influence that child's attitude toward various foods and health. Sickness results often in an over-indulged child with a finicky appetite. This problem may be overcome by hospital teaching.

The outpatient clinic presents another opportunity for constructive work. Waiting is inevitable but may be made more interesting by posters, books, toys, pictures, motion pictures, etc., of which health might be the basic principle.

A clinic offers the possibility of special health instruction to selected groups referred by the physicians for the nutrition or health class. Parental education especially is needed in conjunction with such a group. A child brought to a clinic is often suffering not only from a specific ailment but also from a faulty home routine of food, rest, exercise, etc. Upon the release of the child the responsibility rests completely upon the home and its environment which can be affected only by adult education. Health supervision of the family as a unit, with

the examination of all the children regardless of their condition, has been found of influence by various health organizations. The personnel includes the examining physician who is the foremost teacher, with an assisting worker who is responsible for sound health information and for the motivation of the family group. Home visits by this worker or a social worker are an essential part of the program.

If one accepts the premise that a hospital should sponsor a preventive as well as remedial program, then health education for all groups should be part of the hospital plan.—Mary E. Murphy, *Health Teaching in a Children's Hospital. Arch. Pediat.* 45, 4: 219 (Apr.), 1928.

Changing Points of View in Mental Hygiene—When we are inclined to feel pessimistic about mental attitudes in the present day, it proves encouraging to glance at the progress already made in our appreciation of the real meaning of mental disease and the promotion of mental health. In this article by Elkind we are carried from the period when people thought that the insane were possessed of evil spirits and when it was thought that the proper handling of such a possession was punishment, torture or execution, down to the present comparatively rational idea of mental disease and mental hygiene.

Apparently it was not until the last years of the 18th century that there began to be an appreciation of the fact that the insane were in need of humane medical treatment. At this time asylums were erected for the treatment of the insane who, however, were still consid-

ered to be suffering from a largely incurable disease and one which carried a stigma to the family of the unfortunate sufferer.

It remained for the 20th century, however, to bring into the foreground not only humane medical treatment but rational attempts at the prevention of mental disease and the promotion of mental health.

The conclusion which the author draws is that hygienists now need to do more than advise parents with regard to proper physical health habits. They should also be taught that the proper use of their mental powers is necessary to a working adjustment to life. We must show parents the need of preventing their children from being born with defective mental endowment. The community must be made to feel that "any adequate mental hygiene program must come in contact with or overlap practically all of the various activities of social or community work being done at the present time," and that child hygiene is ineffective unless it means the hygiene of the whole child both mental and physical.—Henry B. Elkind, M.D., Dr. P. H., *The History of Mental Hygiene, J. Outdoor Life*, 25, 4 (Apr.), 1928.

Drop in Infant Mortality—The lowest infant mortality rate ever recorded for Prussia is that for 1926. The figure given, namely, 101 per 1,000 live births, is perhaps high according to certain standards, but is the result of a steady decrease over a number of years in Prussia. Local authorities apparently attribute this decrease mainly to a more general spread of information among the public concerning infant hygiene and the encouragement of welfare work. Breast feeding is being stressed by the Prussian Government through the payment of nursing benefits. Health centers are carried on and their records show a decrease in the amount of mal-

nutrition and a decrease in the incidence of rickets. In 1925, according to the report, 20 per cent of the children examined in 58 cities and rural districts of Prussia had rickets, whereas, in 1926, the percentage was only 10.—*Infant Mortality and Child Hygiene, News Note from Child Welfare News Summary, Children's Bureau*, March 31, 1928, quoting *Volkswohljahrs*, Berlin, Feb. 1, 1928.

Fetal Morbidity—With the increasing realization that the future improvement of infant mortality must come within the early age group, any study of antenatal factors is most timely. The authors of the article here abstracted refer to the usual causes of early infant death such as syphilis, toxemia, disease or malpresentation of the placenta, particularly placenta praevia, operative delivery because of contracted pelvis, excessive size of child, and malpresentation or prolonged delivery from any cause. They also refer in passing to the fact that in the literature may be found reports of a relatively small group of infections such as typhoid fever, scarlet fever, and other acute communicable diseases. Their own contribution consists of two carefully studied cases, one of which was infection with pneumococcus superimposed on syphilis, and the other pneumococcus recovered from the blood of both the fetus and mother indicating to them definitely a maternal transmission.

A review of the literature is given and the following summary indicates the conclusions they draw.

Maternal infections bear an important influence on fetal viability and mortality. The transmission of a general infection takes place through the maternal blood vessels to the circulation of the fetus through apparently unruptured vascular channels. Practically all known specific diseases have been encountered. . . . A review of the literature and our own cases bring to the forefront the importance of the maternal prenatal care. Even such momentarily insignificant minor disabilities as sore

throats and coids should receive the most careful attention.—

Emile Duskes, M.D., and Eva F. Dodge, M.D., Antenatal Infection a Factor in Fetal Morbidity, *Am. J. Dis. Child.*, 35, 2 (Feb.), 1928.

Breast Feeding in Denmark—The little country of Denmark, noted for its advanced ideas in many directions, is reported as showing a steadily increasing recognition of the desirability of promoting the welfare of the child by keeping the mother and child together and seeing to it that living conditions are such that the mother is enabled to nurse her child. They use three methods to accomplish this purpose: One is homes for mothers and babies; another is crèches; and the third is breast feeding stations.

Denmark now has 13 homes providing accommodation for 187 nursing mothers and 375 children. Many towns have well organized crèches which are under official regulation. Infant welfare stations for the promotion of breast feeding are found only in Copenhagen, where, since 1908, there have been 8 such stations in the poorer parts of the city and admitting only breast-fed or partially breast-fed babies, but drawing no distinction between married and unmarried mothers. The mothers visit the station every week or two for examination of the babies and for health instruction. Needy mothers receive a quart of milk a day for their own use and if necessary, free dinners and clothing for the baby. A home visiting

nurse system is also in operation. The statement is made that the stations have cared for nearly 10,000 children since 1908 and of these only 2 per cent died, while under care.—Promotion of Breast Feeding, *National Health*, London, Mar., 1928. (Quoted by *Child Welfare News Summary*, Apr., 1928.)

The Work so far Accomplished in New York City with the use of the Calmette Vaccine Against Tuberculosis—Dr. Park of the New York City Health Department, has been doing some work with the Calmette vaccine in the immunization of infants against tuberculosis. It was given only to babies from tuberculous families and was checked by a control series receiving no treatment. Fifty infants are now under observation who have received the treatment and about twice as many who have not received it. No harmful effects whatever have been noticed in the babies receiving the treatment and none has died of tuberculosis. In the control cases about 7 per cent have died of tuberculosis.

As a result of this work Park goes on record as stating that the vaccine seems to be harmless. He does not fear that the attenuated living bacilli might later become more virulent with resultant damage in later years. He feels justified in carrying out a thorough test especially in view of the apparently successful results obtained in France.—William H. Park, M. D. *Child Health Bull.*, IV, 2 (Mar.), 1928.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Liver Diet—Pernicious anemia is a disease in which, for some unaccountable reason, the red blood cells are destroyed. If this destruction persists and the cells are not regenerated, the outcome is fatal to the patient. For a long time this disease was regarded as practically incurable. Now, however, through the work of various doctors, among whom are Dr. George R. Minot and Dr. William P. Murphy of the Peter Bent Brigham Hospital of Boston, a diet has been discovered which will bring about the regeneration of blood cells. This diet, found to be effective when faithfully continued, consists of the following foods:

Either calves or beef liver given every day in rather large amounts. This should never be fried or prepared with fat.

Fruit containing a low percentage of sugar given twice each day in place of sweet desserts.

Green vegetables make up a large part of the diet. Certain vegetables, such as corn, parsnips, beans, either baked or shelled, should be avoided.

Fairly large amounts of muscle meat, such as roast, steak, hamburger steak, and lamb chops or roast should be taken in addition to the liver. This also should not be fried or prepared with fat.

Dry bread, preferably of the coarser kinds of flour, but not soggy or hot breads, is permitted. Cereals may be taken at breakfast and food, such as potato, rice and macaroni is allowed once daily.

One egg and a glass of milk may also be taken each day.

Fried and fatty foods, except small amounts of butter and cream, and all very sweet foods, except two or three teaspoonfuls of sugar each day, should be avoided.

This article includes a number of ways of preparing liver to make it palatable.—The Minot and Murphy Treatment of Anemia. *Pub. Health Nurse*, 19, 6:278 (June), 1927.

Nursing Education and the Universities in Great Britain—"Great Britain, the cradle of modern nursing, was the second country in the world to establish courses for nurses in connection with universities, the United States having been the first in the field by the greater part of two decades.

"A beginning was made in 1918, when a course for sister tutors—that latest creation in the nursing world and perhaps the most indispensable in the progress of our profession in its many branches—was introduced into the program of King's College for Women, affiliated with the University of London. The satisfactory taking of this 1-year course entitles the student to a College Certificate. The course was established at the request of the association of nurses known as the College of Nursing, Ltd.

"In 1921, the University of Leeds, one of the youngest universities of England, having been incorporated in 1904, established a 'Diploma in Nursing,' to be conferred upon state registered nurses possessing certain qualifications who have followed a prescribed 3 months' course and successfully passed an examination, the latter laying much stress upon practical nursing.

"In 1927, the University of London established a 'Diploma in Nursing,' to be conferred on state registered nurses who successfully pass a prescribed examination. This is, as far as we know, the first examination for trained nurses conducted by a university which is not necessarily preceded by a particular course of some kind.

"The University of London not only examines and confers degrees upon 'in-

ternal students' who have pursued their studies in one of the schools of the university, but also examines and grants degrees to 'external students,' from whom no definite course of study or residence in the university is required; finally the third department is that of the University Extension. Under the present arrangement nurses come under the last and receive their diplomas as a result of an examination without having taken a definite course beforehand.

It is only to be expected that the developments in nursing education in the colleges and universities of Great Britain will be, at least for some time to come, somewhat different from those of other countries, because of the strong traditions of independence and self-government in the higher educational institutions in that land. The English universities, on the other hand, are very similar to those of America and Canada in their admission requirements, the first two or three years of the university curriculum being equivalent to the last two or three years of secondary school in some European countries."—*The I. C. N.* 3, 1:11 (Jan.), 1928.

NOTE: The programs of these university affiliations are described in detail in articles to be found in *The I. C. N.* under the titles, "The Sister Tutor's Course, Kings' College, University of London," by G. V. Hillyers; "Diploma in Nursing, Leeds University," by E. S. Innes; "Diploma in Nursing, University of London," by G. M. Bowes; "Training of Health Visitors in Scotland, University of Edinburgh," by Nora Milnes; and "International Courses at Bedford College, University of London," by Maynard L. Carter.

The Nurses' Official Registry of Buffalo—How one city is meeting the nursing needs of a community to the satisfaction of the public, the nurses and the physicians, is told in the April issue of *The American Journal of Nursing*, by Dr. Thew Wright.

The only professional registry in Buffalo in 1925 was conducted by the

Nurses' Alumnae Association of the Buffalo General Hospital, and during that year a survey was made of nursing conditions in the city. The facts revealed that nursing care was inadequately provided, and that there was much discontent on the part of the professional groups as well as the public. A closer understanding between those three groups was highly desirable. The recommendations of the report of the committee of the New York State Nurses' Association, which made a survey of nursing conditions throughout the state, seemed to offer the solution to the problem of what to do in Buffalo.

The Nurses' Official Registry of Buffalo is now a flourishing concern, having been formed by combining the existing nurses' registries under one head. All applicants are required to be registered according to whether or not they are licensed, trained nurses (State Hospital), trained attendants or practical nurses. All the groups are controlled by rules and regulations applicable to their own amount of experience.

A wise provision is made for a governing board. This governing board has complete control of the registry and consists of representatives from the various nurses' alumnae associations, the medical profession and the laity in the following ratio:

1. One-half the board consists of nurses and includes one representative from each coöperating alumnae association, the chairman of the local League of Nursing Education and one representative for the district branch of the State Nurses' Association.

2. One-quarter from the medical profession, two of whom are appointed by the County Medical Society, the remainder being elected by the board.

3. One-quarter from the laity, selected by ballot of the board.

Much has been done to bring about a good organization and to interpret to the public, in terms of service, the aims and functions of the registry, so that all may know and take advantage of it.

Under the managing board, the director, a graduate, registered nurse, and two assistants (graduate, registered nurses), manage the actual working of the registry. Regular reports are rendered by the director at the board meetings. A committee of censors receives and reports to the board for action all complaints received from anyone.

The Visiting Nurse Association works in close cooperation with the registry. Through it are handled all calls for nurses which come in after regular office hours, the hourly nursing service, and the special night maternity service.

The results so far are:

1. Better understanding is shown between nurses, doctors and patients, due to their combined interest and the splendid cooperation shown between these groups.

2. The nursing situation is in a better state today than before the Nurses' Official Registry was established. The nurses know their interests are being cared for and that they have the backing of an authoritative body when they need it.

3. The medical profession is better satisfied because its wants are far better met.

4. The public finds that its needs are more adequately filled.

Unqualified endorsement by the County Medical Society and the favorable comment heard by individual doctors seem to indicate that the venture is a success. Provision is made for all classes of cases by supplying the various kinds of nurses needed. Surely no one in Buffalo needs to say that nursing care is not available.—Thew Wright, M.D., The Nurses' Official Registry of Buffalo, *Am. J. Nurs.*, XXVIII, 4:321 (Apr.), 1928.

Mutual Interdependence is the Keynote—The seven training courses for Red Cross Chapter workers in the Eastern Area came to a close at National Headquarters in Washington, April 4. The workers attended in the capacity of "students," while the staff members composed the "faculty." Hundreds of students took this opportunity of broad-

ening their own scope and crystallizing their ideas with regard to the work of the Red Cross. There can be no question but that much help was given on both sides in the solution of specific problems that concerned the workers and their chapters.

The courses met with enthusiastic response which argues well for the desirability of having similar courses next year.—*Red Cross Courier*, 7, 8:3 (Apr.), 1928.

NOTE: It seems worth while to mention briefly the main objective now being emphasized as a guide for future development, which is that the Red Cross Nursing Service shall assume a position of permanent responsibility and leadership in public health nursing in the community. Chapter workers are being encouraged to retain their share in the partnership with public authorities in the direction of joint services; to develop new nursing projects where their first ones have been taken over completely by the official health agency; and to render active assistance in the effort to secure uniformity of standards in the service within their county.

Public Need and Professional Response—Many people who should have nursing care do not have it because the nurse's fee seems exorbitant. To them, the services of a nurse seem available only to the very rich who can well pay for them, or to the very poor who can pay nothing. On the other hand, there are many well trained nurses who spend four months out of every year waiting to be called upon.

In many places, the situation is being met by a nursing service on an hourly basis, whereby the patient buys an hour's nursing care, or more, whenever he may need it. This service may be obtained in different ways. In some cities, it may be given by individual nurses, "free lances." In others, it may be procured through nursing registers or through visiting nurse associations.

If hourly nursing is to be a success, there must be developed in each sick member of the community an awareness of nursing practice as it relates to the

needs of the other ill members of the community. On the other hand, private duty nursing service must be organized to meet such needs in the community.

Both the patient and the nurse will benefit by such a service. The patient receives adequate nursing care by one qualified to give it at a price within his means. The nurse has regular employment and time for recreation and growth.—Virginia McCormack, Nursing Mr. Middle-Man, *Survey*, 60, 2:107 (Apr. 15), 1928. B. J. B.

The Picture of the Optimal Child
—These days, so much is heard regarding physical defects and their corrections that we are apt to forget to question the goal toward which we are striving—the perfectly healthy child. What is this perfectly healthy child? How shall we recognize him when we have found him?

Dr. Hugh Chaplin in his booklet *Signs of Health in Childhood*, published by the American Child Health Association, portrays this youngster for us and goes further to tell us what factors combine to build an "optimal" child. The following summary of his pamphlet is taken from the *Boston Evening Transcript* of May 1.

The factors which combine to build an optimal child are: regular meals; sufficient food of the right kind but no overfeeding; plenty of fresh air and sunlight; plenty of sleep with windows open; freedom from unnecessary noise and excitement; baths at least three times a week; brushing teeth twice a day; correction of defects as they occur, for the

detection of which physical examinations are necessary at regular intervals; bappy associations and interesting things to do; pure cod liver oil daily during the first two years except during the heat of summer.

The outward manifestations of a well-functioning body are: an alert, bappy expression; a moist, red and clean tongue; sweet breath; good posture; prompt, efficient muscular co-ordination; bodily repose as shown by freedom from constant and unnecessary activity; ability to indulge in all ordinary exercises without undue fatigue.

A well-built body reveals itself in plentiful hair, with luster due to sufficient natural oil; bright, clear eyes, moving normally, no squinting nor dark fatigue rings, and mucous membranes pink and free from inflammation; the ability to breathe deeply and easily through the nose with mouth closed, especially when exercising and sleeping; teeth well-formed, well-enamelled, clean and free from cavities and set far enough apart to be quite even in jaws, wide enough to provide sufficient space; skin slightly moist, clear, soft and smooth; firm, strong muscles; shoulders not rounded forward; broad, deep chest, with good expansion; long bones of arms and legs straight, joints not enlarged, legs neither bowed outward nor inclined inward; inner and outer sides of ankle equally prominent; arches of feet strong and limber and inner borders of feet straight from heel to tip of great toe.

Optimal children may differ because of the effect of age upon body proportions and upon muscular development, muscular co-ordination and posture and because of variations in rate of growth and types of body build. They will, however, be alike in health and a keen enjoyment of life and bodily efficiency. It is only necessary for parents and children to learn how to live wisely in order that children may become and remain physically and mentally fit.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Twenty - Seven Opportunities— From time to time this department has described various opportunities for special distribution and uses of publicity and educational material of particular interest and value. While this issue of the JOURNAL is being printed the list below has been submitted to workers in the whole field of social welfare at Memphis in connection with the annual meeting of the Committee on Publicity Methods. It is given here to secure criticisms and amplifications with a view to preparing a check list which may be of permanent value to health agencies. The list is provided that every health worker will correct and amplify it to suit his particular field and for his city and state. Have a supply of the corrected list mimeographed, and issue standing orders that 1 copy of the check list together with 12 copies (or other specified minimum number) of every piece of printed or other material be delivered to your desk. You can check the list for special distribution, and specify the special forms of delivery, if any, such as a committee to visit the governor or mayor, personal card, notation, covering letter, etc. Here is the list:

Local: 1—Mayor; 2—Members City Council; 3—Members County Board; 4—Key men and women (start a list); 5—Public Library; 6—Public School Library; 7—College library; 8—Other Libraries.

State: 9—Governor; 10—State Library; 11—State Library Commission; 12—State University; 13—State Extension Department; 14—State Municipal or Legislative Library; 15—Your state association.

National: 16—Your national association;

17—News Bulletin, Committee on Publicity Methods, 130 East 22d St., New York, N. Y. (All samples of good, or especially bad, publicity materials, ideas or technic); 18—*The Survey*; 19—*Better Times*; 20—*American Journal of Public Health*; 21—Education and Publicity Department of A. J. P. H. (Address: Evart G. Routzahn, 130 East 22d St., New York, N. Y.); 22—Library, Russell Sage Foundation (When in New York call and get acquainted); 23—Frederic J. Haskin News Service, Washington (for material possible for a good writer to put into feature article form for national newspaper distribution); 24—Public Affairs Information Service, 11 West 40th St., New York, N. Y. (for all publications of interest to any type of library); 25—Science Service, Washington, D. C. (Send page proofs, etc., of research reports, etc.); 26—*Cumulative Book Index*, 958 University Ave., New York, N. Y. (for all bound books); 27—Library of Congress.

Types of Publicity and Cooperation—Here is a compactly summarized report of the types of publicity used and some of the forms of coöperation given in the recent Early Diagnosis Campaign of the tuberculosis associations. The summary makes an excellent check list of both accepted methods and novel ideas for a health education campaign, as compiled by Dr. H. E. Kleinschmidt of the National Tuberculosis Association.

Special Clinics: Special clinics at County Fair—Florida; Special clinics at night—South Carolina, Los Angeles, Pennsylvania; High school clinics—South Carolina; County health officer plans to give complete physical examination to every high school child during March—West Virginia; Mayor of Boston given chest examination by Dr. Hawes; Demonstration chest clinics with medical societies—Missouri; Special clinic publicity—Maryland; Stage actual chest examination in store window in business section—Minneapolis, Minn.

Coöperation by Sanatoria: Superintendent of sanatorium framed posters to keep them permanently—New Jersey; Offer literature for

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

patients in sanatoria and for them to send to friends—Pennsylvania; Send letters to contacts (names obtained from cases in sanatoria) urging examinations—Wisconsin; Special letter to ex-patients of sanatorium asking their return for examination—Camden, N. J.; Superintendent State Colored Sanatorium sent personal letter to all negro physicians and dentists about Charleston asking coöperation and telling of clinic scheduled by him.

Boy Scouts Coöperate: Boy Scouts distribute pamphlets in theatres with showing of film—Morristown, N. J.; Boy Scouts place posters in schools, buses, pool rooms, and trolleys—Oil City, Pa.

Radio Coöperation Radio Stations—WLAC, WSM, WEA (Bagley), WHO, WEEL, KWK (Weekly talk), KNOX, WCAU, WMC; State Commission of Health broadcast E. D. C. talk (Massachusetts and Tennessee), seven stations in Chicago, Ill., and others not named, four talks in Pittsburgh, Pa., two talks in Detroit, Mich.; Radio talk with question and answer period (suggested by Dr. Plunkett, New York); Radio talk on negro tuberculosis problem—Pittsburgh, Pa.; National Life and Accident Company offer radio station—Nashville, Tenn.

Posters and Posterettes: State Department of Labor and Industry distributes posters (11 x 14); Railroads place posters in waiting rooms and shops—Texas; Special poster for "L" billboards—Brooklyn, N. Y.; Illuminated billboards—Pittsburgh; 2,000 posters, 9 x 12, on trolley car dashboards—Connecticut; Poster in every schoolroom and circular for every pupil—West Virginia; Posterettes through light company—Florida; Posterettes through light company with statements—Massachusetts; Posterettes on state health department mail—West Virginia; Windshield posterettes distributed to all autos by garage men—Massachusetts; Posterettes to be used in schools and in pay envelopes of large industries; A. & P. stores each display two posters—Detroit, Mich.

Films: Show film before state and local medical associations and societies; show film in jail—St. Louis, Mo.; Show film in hospitals to internes and nurses—St. Louis, Mo.; Show film to mothers' club in schools—St. Louis, Mo.; Tuberculosis clinic units of State Department of Health show medical film in every county of state—Tennessee.

Coöperation of Motion Picture Theatre Owners: Motion picture theatre owners send letter with slides to operators to assure use; Lecture and films presented to theatre audiences.

Coöperation by Special Groups: Corporations conduct series of E. D. C. meetings for

employees (600 in one Maryland meeting); Ministers mention E. D. C. in churches; Detroit Council of Churches—Detroit, Mich.; Federation of Women's Clubs—Detroit, Mich.; Insurance company's examiners gave talks to agents who carried message and distributed literature to policy holders; Public meeting for health play and movie—Lowell, Mass.; Noon meetings at industrial plants—New Jersey; Distribution of literature to employees—West Virginia; County health unit paid for half of supplies—South Carolina; University of Alabama School of Medicine asked for copies of Diagnostic Standards; Ask council of Lions Clubs to offer prize for best publicity in weekly community papers—Chicago, Ill.; Airplane bombing of cities with tuberculosis literature and prizes for marked copies—Minnesota and Troy, N. Y.; Coöperation and endorsements from druggists for window display—chain stores and state druggists association (Pennsylvania), retail druggists association (Newark, N. J.); Coöperation of Dental Society—speaker, posters, and article in magazine—Chicago, Ill.; Class discussion of E. D. C., Normal School—Newark, N. J.; Prizes for essays on tuberculosis offered by county association—California; Talks to foreign groups with interpreter—Michigan.

Coöperation by Individuals: Prayer by the Rev. S. Parkes Cadman; Special coöperation on Pacific Coast by Dr. Shepard, Welfare Division representative of Metropolitan Life Insurance Company, show film and distribute posters and posterettes; E. D. C. proclamation issued by governor—Wisconsin; Special interview released by state health officer—Wisconsin; School Commissioner sent letter to teachers asking them to use posters and distribute literature.

Coöperation by Medical Societies: American Hospital Association urged members to distribute literature through clinics and outpatient departments and to old patients and medical and nursing staffs; State Committee of Health sent out "Tuberculosis Abstracts" with weekly letters to officers of all county medical societies during March—Iowa; State Medical Association sent out two tuberculosis articles as part of publicity services—Indiana; Special meetings for physicians arranged through county medical societies; Insert "Appeal to the Medical Profession" in copy of *State Medical Journal*; State-wide committee consisting of heads of various medical and health organizations; Speakers bureau for physicians; Special regional post-graduate tuberculosis clinics for doctors connected with medical societies.

Types of Endorsements: American Public Health Association—story in JOURNAL and editorial; American Medical Association—story in

Journal; State Medical Societies—Pennsylvania, Massachusetts, Louisiana, West Virginia, Iowa; State Medical Associations—Georgia, Louisiana, Idaho; Gorgas Memorial Fund—sent out publicity and stressed tuberculosis in talks; Pennsylvania State Federation of Labor sent letter to each local and E. D. C. literature and posters; State health departments in West Virginia, New York, Iowa, Ohio, Utah, Maryland, Florida; State Health Department of Pennsylvania sent "Appeal to the Medical Profession" to 12,000 doctors in state; State Drug-gists Association—Pennsylvania; State Department of Labor and Industry, Pennsylvania, distributed 10,000 posters; State Association of Boards of Health—Massachusetts; Baltimore City Medical Society; State Federation of Women's Clubs; Pennsylvania Congress of Parents and Teachers—sent letter to locals urging special E. D. C. March meetings; State Y. M. C. A. sent letter and samples of E. D. C. literature and posters to all regular, railroad and college local associations; Detroit Council of Churches; Knights of Columbus; American Hospital Association; Maccabees program—Plan of E. D. C., talk on symptoms, play, distribution of literature.

Magazine and Newspaper Publicity: Special "boiler-plate" sent out by Pennsylvania and Wisconsin; Special manual on Health Endeavors written for Boy Scouts—Michigan; Special "Broadside" for teachers—Michigan; House organs carry items; The Doctor Speaks, special pamphlet for doctors and patients urging sanatorium treatment, not home treatment, offered to locals by New Jersey; Full page ads. donated by papers—New Jersey; Pennsylvania Railroad News ran editorial; Special articles by physicians used in newspapers—Missouri; Metropolitan Life gave ads. in March magazine (articles and editorials in magazines); Offer to papers box mat and six daily items on symptoms to be run under it—Ohio; Send locals general stories with definite release dates—Ohio; Special weekly sets of fillers to newspapers—Kansas; Send out reprints of two Medical Journal articles on E. D. C.—West Virginia; Special E. D. C. circular for negroes, New York Tuberculosis Association; Special plate material—4 articles by prominent physicians—Wisconsin;

Let Your Doctor Decide: Working through 150 service clubs arranged meetings for distribution of circular—Alabama; Circular distributed by state labor department and insurance companies—Washington, D. C.; Distributed through schools, social and civic organizations; Sent out in letters by locals—Delaware County, Pa.; Through morning butter and egg men—Chicago, Ill.

Special Stationery: Special envelope—Pennsylvania; Special letterheads by state associations—Michigan, Alabama, West Virginia.

Miscellaneous: Three puppet shows—Wisconsin; Cards in buses—New Jersey; Appeal to the Medical Profession distributed to every doctor in city and state; Tie-up with "Girls Health Trail," special window display used—Chicago, Ill.; Combine second Christmas seal follow up and E. D. C.—Atlanta, Ga. and Minneapolis, Minn. Special letter to territorial nursing supervisors of Metropolitan Life Insurance Company to coöperate with local associations.

"The Most Valuable Eyes in the World"—An exhibit usable in fairs and expositions was worked out in coöperation with the Health Shop of the East Harlem Health Center of New York City.

The Health Shop put up a booth on the pavement outside of its building which was used for exhibits along various health lines, each exhibit staying in place for two weeks' period and then giving way to another health organization. When the National Society for the Prevention of Blindness was called on, two nearly life-size cut-outs were placed in the booth demonstrating proper posture in the school child and correct use of light both in the home and at school. At either end of the booth facing up and down the street a mirror was placed, underneath the note in large lettering, "The Most Valuable Eyes in the World" and at the top of each mirror was written "See!" These mirrors attracted people's attention to a great extent and persons passing up and down the street stopped to notice the cut-outs.—

Eleanor P. Brown.

AWARDS

A liberal share of awards was made to health organizations in the awards made by the Committee on Publicity Methods at the recent meeting in Memphis. The report of the Committee on Awards included the following:

House organs or official bulletins sent to contributors: In this group the *Quarterly Bulletin* of the Milbank Memorial Fund stands out above all other entries as a piece of printing. Throughout its pages type matter and illustrations are nicely balanced. Its appearance and readability might have been still further improved by a judicious use of sub-heads, but in the main it is excellently done

and monotony is avoided by varying the size and form of the cuts, and by the use of both single and double columns of type, with ample margins of white space. The booklet also rates well in literary quality and adaptability to its purpose. It is easily entitled to first prize.

Annual reports: Of the score of entries we like best *A Year in Review* put out by the National Society for the Prevention of Blindness. It is a report that commands attention and our guess is that it rarely finds itself in the waste basket until it has been read or at least thumbed over. On every point this booklet scores high, and it is especially commendable for its use of photographs in illustrating the work. And it is worth what it cost.

The Community Health Association of Boston is accorded first honorable mention for its interesting use of art work and color. This is a fine example of letting the picture tell the story.

Booklets issued as part of a year-round publicity program: Iowa Tuberculosis Association carries off third honors with a series of leaflets, folders and other printed matter. This in spite of a quatrain that appears on the same page with the rather famous soliloquy of a cent.

Printed Novelties: Our second choice is the annual report of the Visiting Nurse Association of Omaha, not because it is patriotically printed in red, white and blue, but because it tells the complete story in a brief and novel form.

TIMELY TOPIC

Beware the Mad Dog—*Weekly Health Review*, Detroit Department of Health. April 7, 1928.

MOTION PICTURES

A brief department, "Amateur Film Making," by Dwight R. Furness, now appears in *Educational Screen*, 5 South Wabash Ave., Chicago, Ill. 25 cents. Some suggestions on acting for a picture appear in the April issue. *For some uses* amateur productions can be quite helpful. (*We would like to show an amateur picture at Chicago in October.*) Mr. Furness will supply a constitution for a local amateur movie club.

If you need light on motion picture portrayal of your health activities—

especially if located in a community chest city—you will wish a copy of the report on a recent review of such pictures. Sent *free* by Committee on Publicity Methods, 130 East 22nd St., New York, N. Y.

The Children's Bureau is producing a film to show that the breast fed baby is the best fed baby not only because it is much easier for the mother to nurse her baby than to prepare formulas and sterilize bottles, but because the baby who is breast fed has four times the chance for life that the bottle fed baby has. A sequence on manual expression is to be included.

"Sniffle's Snuffles" is the recent addition to the New York State Department series of short pictures. This presentation of facts about common colds is a combination of cartoon animation and living silhouettes, with a thread of story. The series is planned for theatre presentation—with a maximum of entertainment, a minimum of length and one basic health idea in each picture. The producer, Carlyle Ellis, reports that about 25 states are using it.

A 7-minute picture, "Beware the Pitfalls," released by the New York Tuberculosis and Health Association, was produced by Carpenter and Goldman under the technical supervision of Dr. Iago Galdston, secretary of the Health Education Service of the Association. "Beware of the Pitfalls" dramatizes a number of vital statistics of children under 10 years of age through animated drawings. The animation represents a procession of children moving in silhouette across and upward in the direction of a stronghold labeled "Health Maturity." As they move on, numbers of them are shown falling out of line and into pits. These pits are each labeled, "Diphtheria," "Measles," "Scarlet Fever," etc., and are referred back to the actual numbers and rates for each illness.

LAW AND LEGISLATION

JAMES A. TOBEY, LL.B., DR.P.H.

Triumph at Hand—With surprising equanimity and nary a wrangle, the Parker Bill, already adopted by the House, was passed by the United States Senate on April 24, 1928. The Senate did, however, write in a number of amendments which had been suggested or demanded by Senator Smoot. With one or two exceptions, none of these amendments is of vast significance and most of them actually improve the bill. On April 28, however, the House voted to disagree with the Senate amendments and both branches thereupon appointed conferees. An agreement was soon reached and the Senate accepted the report on May 7, and the House on May 10. The bill then went to the President for signature.

The most important amendment insisted upon by Senator Smoot is a provision limiting the tenure of office of the Surgeon General of the Public Health Service to 8 years, or 2 terms. Another amendment restricts the number of sanitary engineers, dentists, and other non-medical scientific personnel who can be given a commissioned status to a total of 110, with only 6 allowed above the grade of surgeon and none above the grade of medical director. Pharmacists may not be appointed above the grade of passed assistant surgeon.

Hearings on the Ransdell Bill (S. 3391) to create a national institute of health were held the latter part of April.

France Wants Its Ministry of Health Back—Five years ago a ministry of health was created for the first time in France. Two years later, when the ministry of M. Poincare fell, the ministry of health was combined with

that of labor, and labor soon proceeded to submerge health in the ministry. Now, according to the Paris correspondent of the *Journal of the American Medical Association*, writing in the issue of April 7, 1928, the French Academy of Medicine demands that a separate ministry of health be set up again because the public health services of France have become badly disorganized during the past 3 years. The Academy cites the interesting fact that only 3 million francs are allotted by the French government for public health, whereas 300 million francs are appropriated for social assistance and public welfare.

Ventilating Congress—When a little item of \$323,000 for a system of improved ventilation in Congress came up in the House on April 14, the members immediately displayed unusual interest in public health. The proposition was warmly debated and there was much discussion of an investigation of the air in Congress made for the Public Health Service by a committee consisting of C-E. A. Winslow, chairman, Frank Irving Cooper, A.M. Feldman, D. D. Kimball, F. R. Still, R. E. Hall, and A. C. Willard. There were also many references to testimony by Dr. L. R. Thompson and Dr. Leonard Greenburg at the hearings which had been held on the appropriation measure in which this sum occurs.

Opposition to this outlay came from Representative Summers, who is a physician, and from Representative Bloom, who is or has been in the theatrical business. During the debate the following interesting dialogue occurred:

Mr. Summers of Washington—"But I would not spend a third of a million

dollars to turn the heat off in my home."

Mr. Taylor of Colorado—"I would spend a million dollars to save the health of the American Congress."

The House evidently thought it was worth the \$323,000 because they passed it. Would they be as eager to appropriate comparatively as much for the health of the 110,000,000 or more people of the United States as for the 531 members of Congress?

Relief for Drug Addicts—In the 3 federal prisons in this country there are 3,778 hospital beds, but the number of inmates is 7,598 and of this number 1,559 are drug addicts. These facts were brought out at hearings held on April 26 on H. R. 12781, Representative Porter's bill for 2 federal narcotic farms. Col. L. G. Nutt of the Bureau of Prohibition, various prison wardens, alienists, and others indorsed the measure.

The conservative and indifferent attitude of European nations precludes any effective international regulation of narcotics, according to Assistant Surgeon General Rupert Blue in testifying at the hearings on April 28. He appeared in support of Mr. Porter's bill. Such international efforts as there are dealing with the traffic in opium were outlined in a letter sent by Secretary of State Kellogg to Senator Smoot on April 4. This letter appears in the *United States Daily* of April 5, 1928.

Hospitals for Veterans—The lady from Massachusetts, Mrs. Rogers, arose in the House on April 16 and moved that the rules be suspended and H. R. 12821 be passed. It was. This bill contains authorization for an appropriation of 15 million dollars for additional hospitalization facilities for world war veterans. Last year a similar bill carrying, however, only 11 million dollars, passed the House but failed in the Senate on account of the filibuster with which the Senate then closed its attention to the

public welfare. That filibuster apparently cost the country at least the 4 million dollars added to this hospitalization bill.

Adoption of a bill, H. R. 12627, to establish a medical corps in the U. S. Veterans' Bureau was urged at hearings on April 12. Among those favoring this measure were Dr. Llewellys F. Barker, Col. R. U. Patterson, Dr. W. F. Lorenz, Dr. Kennon Dunham, and Dr. B. W. Black, the last named now being medical director of the bureau.

Other Health Bills in Congress—The bill, H. R. 8128, to authorize an appropriation for the Gorgas Memorial Laboratory, which has passed the House, was passed by the Senate on April 24, the same day the Parker bill was adopted. The resolution for a monument to General Gorgas was reported to the Senate on April 27 and passed a few days later.

Authority to mail poisons under rules and regulations of the Post Office Department is contained in a bill, H. R. 10441, reported to the House on April 18. The bill would permit manufacturers to mail to physicians and others drugs and other articles of a poisonous nature. A similar bill, S. 3127, passed the Senate on May 10.

Members of the civilian army, that is, reserve officers, national guard, and those attending citizen's training camps will be entitled to government medical care for injuries or disease according to S. 2948, which passed the House on April 16. On April 21 the House passed a bill, H. R. 12063 for the relief of the widow of Surg. M. W. Glover of the U. S. Public Health Service.

A joint resolution designating May 1 as Child Health Day was adopted by Congress and President Coolidge issued a proclamation to this effect on April 28.

The bill, S. 3554, for an investigation of cancer, was reported to the Senate on April 12.

Hearings on the Haugen bill, H. R. 10958, to widen the provisions of the Oleomargarine Act were held on April 17 and 19. One witness contended, according to the *United States Daily*, that the bill was designed to aid the members of the Institute of Margarine Manufacturers in a bitter trade war against certain independent firms.

Food and Drug Laws and Public Health—Whether or not food and drug legislation belongs to the domain of public health has always been something of a moot question. In an interesting paper which was presented before the Food and Drugs Section of the A. P. H. A. and has been printed in the *Home Economist* for April, 1928, Walter S. Frisbie, Ph.B., discusses all aspects of this subject and reaches the conclusion that, "the enforcement of the food and drugs law, at least those of a general or non-specific character, is not essentially a health department function."

In spite of this fact, 17 states have entrusted their food and drug legislation to state health authorities. The Federal government, on the other hand, has turned the administration of the national food and drug laws to bureaus of the Department of Agriculture. During the 20 years or more of federal activity in this matter, the health factor has rarely been involved, according to Mr. Frisbie. When public health has been concerned, the Department of Agriculture has frequently called upon the U. S. Public Health Service for aid. Such coöperation, also existing between federal and state and city governments, ought to be extended, in the opinion of this writer.

Although the economic phases of food and drug legislation may be of paramount significance, Mr. Frisbie points out that, public health may be affected by foods which contain poisons, are infected with pathogenic organisms, or are possessed of toxins, and he closes his article with the suggestion that "the

relation of food and drug laws of even the broadest or most general type cannot be ignored in any comprehensive program of public health work."

Liability for Water-borne Typhoid—Any corporation, either private or municipal, in the business of supplying water for human consumption will find it a good investment to employ adequate methods to protect the purity of the water. The first cost and the operating expenses of chlorination, for instance, are fairly certain to be far less than the award for damages to parties injured by polluted water. Such, at least, has been the experience of a number of careless corporations who permitted typhoid fever to be spread by their water supplies.

Court decisions in 8 states during the past 40 years have settled the law of liability for water borne typhoid. An individual or corporation supplying water for people to drink must exercise every reasonable effort to ascertain the quality of the water and take every possible precaution to render it safe. While not a guarantor of the purity of the water under the legal doctrine of implied warranty, the corporation which furnishes it is liable for negligence in exercising due care to apprehend and avert danger.

The decisions of all the courts of last resort on this important matter up to 1927 are summarized and discussed in a comprehensive article in *Public Works* for April, 1928. The Wallace & Tiernan Company of Newark, N. J., has asked permission to republish this article and reprints of it may be obtained from that organization.

Miscellaneous Items—Washington is living up to its reputation as a center for high-powered conferences. From April 2 to 5, 1928, the Children's Bureau held its fifth annual conference on maternity and infancy. Forty-two coöperating states and 3 still outside the fold

sent official delegates. Cancer was the topic for a conference called by the Surgeon General of the U. S. Public Health Service on April 9, 1928.

Surgeon General H. S. Cumming departed for Europe on April 20 to attend meetings of the Health Section of the League of Nations. He was to return the latter part of May.

Sanitary Engineers of the U. S. Public Health Service have been assigned to assist the Office of Indian Affairs in connection with various sanitary improvements at schools and on Indian reservations.

Hygienic Laboratory Bulletin No. 150, entitled "Key-Catalogue of Insects of Importance in Public Health" by C. W. Stiles and A. Hassall has recently been issued by the U. S. Public Health Service. This publication is said to be of value to lawyers interested in nuisances and medical jurisprudence.

A pension due a health department employe under the New York City

charter cannot be withheld by the commissioner of health on the grounds that the employe was suspected of having indulged in questionable activities, according to *Graef v. Department of Health*, 227 N. Y. S. 82, decided by the New York Supreme Court in January.

An excellent summary of tendencies in workmen's compensation laws is given in *Insurance Bulletin No. 32* of the Chamber of Commerce of the United States. This bulletin has a valuable tabulation of compensation provisions.

Summer Public Health Institute—Half a day will be devoted to public health law during the second Public Health Institute for health officers and other public health workers to be held at the Massachusetts Institute of Technology from July 2 to 24, 1928. Persons interested should communicate with Professor S. C. Prescott at M.I.T., Cambridge, Mass.

CONFERENCES

June 4-9, Biennial Nurses Convention, Louisville, Ky. (American Nurses Association, National League of Nursing Education, National Organization for Public Health Nursing)

June 8-9, Conference of State and Provincial Health Authorities of North America, St. Paul, Minn.

June 12, American Heart Association, Minneapolis, Minn.

June 12-14, Ontario Health Officers Association, 14th Annual Meeting, Toronto, Ont.

June 18, Regional Meeting, American Public Health Association, Portland, Ore.

June 18-23, National Tuberculosis Association, Portland, Ore.

June 20, Canadian Tuberculosis Association, Charlottetown, P. E. I.

June 26-28, New York State Conference of Health Officers and Public Health

Nurses, Saratoga Springs, N. Y.

July 1-6, National Education Association, Minneapolis, Minn.

August 6-10, American Hospital Association, San Francisco, Calif.

October 15-19, American Public Health Association, Chicago, Ill.

FOREIGN

July 8-12, Congrès International de la Protection l'Enfance, Paris, France.

July 8-13, First World Congress of Social Workers, Paris, France.

July 16-21, Thirty-ninth Congress Royal Sanitary Institute, Plymouth, England.

July 28-August 4, World Federation of Education Associations, Geneva, Switzerland.

December 28, International Congress of Tropical Medicine and Hygiene, Cairo, Egypt.

BOOKS AND REPORTS

Standing Room Only?—By Edward Alsworth Ross. New York: Century, 1927. 368 pp. Price \$3.00.

In this book the author has given us a study of the growth of population as compared with that of food supply. His survey covers practically the entire world, and he shows, as others have done, that the population almost everywhere is increasing at a tremendous rate, owing largely to the advances in preventive medicine. He proves that in many parts of the world, particularly those inhabited by the brown races, the population is already greater than the food supply, though there is no indication of any effort to control this increase. Indeed preventive medicine is enlarging its boundaries at a tremendous pace, and infants whose lives ordinarily would have been sacrificed are now saved to grow up and propagate their kind. In two of the most overcrowded countries, India and China, there are habits, beliefs, and superstitions, which practically compel large families, as sons are necessary to perform certain rites—ancestor worship, for example.

The author is a strong believer in birth control and many arguments are brought forward to sustain his point of view. Excerpts from a number of letters written to Mrs. Sanger by women in many stations of life are quoted. He seems too much inclined to regard this measure as a panacea for the ills of which he writes. He is a great admirer of Malthus, though he considers the famous *Essay* as no longer fit to guide us, since so many new factors have arisen which interfere with the predictions made by its writer. He feels, however, that Malthus has left an enduring mark upon the dynamics of

population, a statement with which all students will agree.

Professor Ross is a well-known maker of phrases, and a fluent writer. Unfortunately, the medical part of his argument is marred by mistakes such as are so commonly made by non-medical men. For example, on page 34, he gives the date of the discovery of the bacillus of whooping cough as 1906, while on page 35, he classes whooping cough as among the diseases still under discussion, though believed to be of parasitic origin. He gives 1919 as the date of the discovery of the cause of yellow fever, though this alleged discovery has been completely discredited. On page 36, the word "toxin" is loosely used.

The book includes a number of articles previously printed in various magazines. It can be recommended as interesting reading, and as giving many facts on a question which is much under discussion in every part of the civilized world. The advances of preventive medicine in life-saving certainly bring with them problems which must be answered in the near future, since our population is increasing at a rate, which if unchecked, will soon leave us with "standing room only."

M. P. RAVENEL

Fighters of Fate—By J. Arthur Myers, Baltimore: Williams & Wilkins, 1927. 318 pp. Price \$3.00.

The art of the world has gained and also suffered because of the fact that many men of genius have been afflicted with tuberculosis. While suffering from this disease, Frederic Chopin, produced some of his most marvelous compositions, and John Keats wrote his "Ode to a Grecian Urn." But Chopin died

prematurely at 39, and Keats at 25. History is replete with similar occurrences.

Tuberculosis is not the reason for genius, but sometimes, as in the case of Eugene O'Neil, the playwright, the rest required allows the development or realization of native powers. The consumptive of the 18th and 19th centuries usually fought a losing fight, though in many instances he attained great things despite his adversity. The tuberculosis patient of today has better than an even chance to achieve greatness and overcome the disease and many of them, such as Roger W. Babson, Harold Bell Wright, Will Irwin, Albert E. Wiggam, Lawrason Brown, and McDugald McLean, have done so. The biographies of these men and others, twenty-four in all, are presented in this volume by Dr. Myers, himself one of the fighters of fate. Except for St. Francis of Assisi, who was born in 1182 and died in 1266, most of the subjects mentioned belong to the latter part of the 18th or early part of the 19th century. The lives of poets and musicians, writers and physicians, an empire builder and a baseball player, are passed in review in an interesting, if somewhat sketchy, manner.

The book is simply written, with the chief incidents of the various biographies concisely presented. While it lacks some of the romance which might have been woven into the story, it is well worth perusal. The book is well printed. There is an introduction by Dr. Charles H. Mayo.

JAMES A. TOBEY

Critical Studies in the Legal Chemistry of Foods—By R. O. Brooks, B. Sc. New York: Chemical Catalog Co. Inc., 1927. 280 pp. Price \$6.00.

This is a compilation of articles published in trade journals, chiefly in 1922 and 1923. It covers only a small portion of the food field; includes fruits and fruit products, condimental sauces,

edible oils, cacao products, spices and maple products.

Because of being a reprint of material prepared some five or six years ago, which in turn referred to other material, then, five, ten or more years old, much of the book is now quite out of date.

The scheme followed in each chapter is to define the basic natural food materials used, to describe the technology employed in preparing these for market, and to give the tolerances (usually and improperly called "standards") which for the information of the trade have been issued by the federal government; together with some argument as to whether in the author's opinion, those tolerances are fair and proper.

The many food inspection decisions of the federal government regarding tolerances for those food products discussed in the book appear to be correctly quoted and to many readers may prove to be the most valuable portion of the book. However, these can be secured, without cost, by interested parties who write for them to the U. S. Department of Agriculture. The value which these tolerances might have in the book is, however, distinctly reduced by reason of the fact that the author is not content to quote those now in force but repeatedly confuses and befogs the issue by quoting old, discarded tolerances in which he, as well as the government which superseded them with other and better ones, had in the past found some weakness. Against these old and abandoned "standards" the author directs the shafts of his criticism *in extenso*. It is believed that this constitutes the basis for the use of the word "critical" in the title of the book.

There is a tendency throughout the book to overemphasize the difficulty of the examinations which must be made to detect adulteration. As an example, in the chapter on spices, the author takes the position that to discover the adulteration of cloves with excessive amounts

of clove stems requires the services of a "skilled spice microscopist." The fact is that any careful, conscientious laboratory helper, charwoman or other person of ordinary intelligence and average eyesight, with very little instruction, and certainly without the aid of a microscope, could do the job well.

There is an appendix of some 40 pages containing reprints of articles by other authors, chiefly on the technology of preparing fruit beverages, jellies and mayonnaise and on the labelling of beverages and beverage materials.

Those who believe that the enforcement of the Federal Food and Drugs Act has been constructive in its conception, just in its execution and salutary in its effect, will not agree with the author's statement on page 64.

H. W. REDFIELD

What You Should Know About Health and Disease—By *Howard W. Haggard, M.D.*, with an introduction by *Yandell Henderson*. New York: Harper, 1928. 538 pp. Price \$5.00.

Since the war we have had a veritable deluge of books pertaining to health, a few of which have been very good, but most of which have been mediocre or even poor. The present volume comes to us in a jacket, for which the author must be at least indirectly responsible, which would lead us to expect a good deal of it, since we are told that it "extends over the whole field of modern medicine" and "makes available to the general reader in one volume the knowledge which modern medical science has accumulated."

It is dedicated to Professor Yandell Henderson, who is thanked for his service in "its delivery." Just what the "delivery" of a book means is hard to say. Professor Henderson writes a rather fulsome introduction, in which, after naming certain classes of readers, he ends by commending the book to the "whole educated public." We believe

that the uneducated public is the section of the community which most needs a book on health.

It is interesting to study the different points of view from which books on health are written. The present book leans decidedly to physiology. We believe that no sound hygiene can be taught without at least a fair knowledge of anatomy and physiology. These two subjects are well and adequately treated. The public health side strikes us as being spread in a very thin layer. There are many things to which exception might be taken. Cocksure statements are made on subjects concerning which experts speak carefully. There are a number of misspellings, some of which may be passed by as typographical errors, though we can see little excuse for them even on that ground. Other errors, however, are so often repeated that one cannot blame the printer or a careless proof reader. One also finds terms which are not used in modern books. We cannot see why statistics for 1908 should be quoted when those for 1926 or 1927 are available.

The make-up of the book is excellent and the illustrations are good.

M. P. RAVENEL

Dunn's Food and Drug Laws, Federal and State (Annotated)—*Prepared and Edited by Charles Wesley Dunn, M. A.* In 3 volumes. Vol. 1, *Federal*. Pp. 775; Vol. 2, *States, Alabama-New Hampshire*. Pp. 1618; Vol. 3, *States, New Jersey-Wyoming, Appendix-Index*, Pp. 3418. New York: The United States Corporation. 1927. Price \$50.

To find the complete written law on any one subject in this country, it is usually necessary to consult, as a conservative estimate, not less than 250 volumes. This is because the written law in the United States is scattered in the codes and session laws of 48 states, in those of the several territories, and

in the statutes of the federal government. This legislation is, furthermore, often reinforced by administrative rules and regulations, and by executive decisions. Finally, it is also subject to the interpretation and application by courts of last resort.

When, therefore, an attorney performs the very real service of bringing together all of the laws and regulations, properly annotated, on any one subject, he deserves a vote of thanks from all persons interested and concerned. This is especially the case when the compilation is accurate and conveniently arranged.

Frequent consultation of *Dunn's Food and Drug Laws* by the reviewer has shown that these three volumes are indispensable to anyone dealing with food and drug legislation. This monumental work is of great practical value and should be in many libraries, despite its considerable, though proper, cost. The books are well printed, apparently reasonably free from errors, and the subject matter is unusually complete.

The fact that nearly 6000 pages are needed to present one single phase of law is an interesting commentary on American law-making proclivities.

JAMES A. TOBEY

The Prohibition Mania, A Reply to Professor Irving Fisher and Others—By Clarence Darrow and Victor S. Yarros. New York: Boni & Liveright, 1927. 254 pp. Price \$2.50.

This book is a devastating criticism of Professor Irving Fisher's *Prohibition at its Worst*, as well as of Professor Fisher himself. Point by point his claims are taken up and their unfairness, their lack of logic and scientific accuracy are shown up. In doing this, a number of well-known writers on economics, medicine, psychology, etc. are quoted. One of the most striking of these quotations is taken from Professor Willcox of Cornell University, one of our

best known statistical authorities. On various points, authors like Pearl, Stockard, Pearson, Starling, Münsterberg, and others are quoted. A considerable amount of space is devoted to criticisms of the charts given by Professor Fisher to prove his case. It is brought out that many of these charts are based on the work of R. A. Corradini, who is connected with the World League Against Alcoholism, and further that they do not represent actual figures. In fact, they are spoken of sometimes as "estimates" and in one place as a "shrewd estimate." Indeed it is shown that most of them are simply guesses with little or no foundation in fact.

The study of the use of alcohol is not confined to the United States but examples are drawn from a number of other countries also. We can commend the book to all who wish to know both sides of this burning question. A note is inserted stating that while the book was in the hands of the publisher a new edition of *Prohibition at its Worst* came out, in which the charts have been changed. Readers are advised to use the first edition of Professor Fisher's book, though the authors feel that the new edition with the changes "will hardly deceive intelligent people."

The authors are both well-known. They write as "convinced individualists" and in the reviewer's judgment, they make out a good case.

M. P. RAVENEL

American Red Cross Text Book on Food and Nutrition—By Ruth Wheeler. Philadelphia: Blakiston, 1927. 123 pp. Price \$.60.

This is a book which gives a definite working knowledge of the selection of foods, and would be an excellent text to place in the hands of the worker who wishes to organize nutrition classes, or the nurse who needs lists and charts, and the recent thought on food selection.

D. D.

Percival's Medical Ethics—*Edited by Chauncey D. Leake. Baltimore: Williams & Wilkins. 1927. 291 pp. Price \$3.00.*

This book is divided into three parts—the first an introductory essay on ethics and medical ethics; the second, Percival's Medical Ethics, with a facsimile of the original title page; and lastly, appendices giving the so-called Pagan Oath of Hippocrates, the oath in so far as a Christian may take it; the code of ethics of the American Medical Association, adopted May, 1847; the principles of ethics of the same association for 1903 and 1912, revised to date. A reproduction is given of the manuscript form of the earliest extant version of the Christian Hippocratic oath, taken from a manuscript of the 10th or 11th century preserved in the Vatican.

In these days when medicine is being so largely regarded as a business instead of a profession, this volume is particularly timely, and we feel that the author has done a service in collecting this material and presenting it in such good form. It represents a great amount of labor. Not being a physician, he apologizes for discussing what some may consider a strictly medical subject, but he approaches it in a sympathetic manner and in the attitude of one who is connected with medicine. There is little question that medical ethics are misunderstood by laymen as well as by many physicians, and that some, even of the latter, do not appreciate the underlying principles, which we believe are founded on the Golden Rule. The letter of Percival accompanying a copy of his *Manual* sent to his son, enumerates a number of advantages which will follow the study of professional ethics, and result in "that propriety and dignity of conduct which are essential to the character of a Gentleman."

A distinction is drawn between medical etiquette, involving physicians

alone, and matters of ethical significance to humanity, but which are often confounded in practice.

The book can be read with advantage as well as pleasure by all professional people. To the general public and especially that portion of it interested in history, it can also be highly recommended. It is beautifully printed, and contains a number of unusually interesting illustrations.

In connection with this book, we wish to call attention to an article by Acting Dean Carey, of Marquette University, on the use of the Hippocratic Oath in medical schools. Thirteen of 79 schools require their graduates to take the Oath before the degree in medicine is conferred. Some other schools contemplate its use, and still others read it to freshmen and to seniors on special occasions. Some modifications, which embody the essential principles, are employed.

M. P. RAVENEL

Report of the Medical Research Council for the Year 1926-1927. —*London: His Majesty's Stationery Office, 1928. Price 3s.*

Annual reports are often dreary reading, but the volume before us is a notable exception. Some parts of the report, such as that on Artificial Vitamin Production, for example, have the value of original articles. The subjects considered require two full pages, and they cannot even be mentioned in a review. We can only say that from cover to cover this Report is full of valuable facts and suggestions for further research work.

We know of no other body which, since the World War, has contributed more to public health than the Medical Research Council of England. It has the best research minds in the kingdom working earnestly under a council of notable scientific men, headed by the Earl of Balfour as Chairman.

M. P. RAVENEL

Annals of the Pickett-Thompson Research Laboratory, Volume III (complete). Baltimore: Williams & Wilkins, 1927. 316 pp. Price \$10.00.

This monumental work, devoted entirely to the streptococcus group, shows the thoroughness characteristic of English research. In some ways it is rather disappointing, since it does not take into consideration the pathogenic varieties as was intended, since such an enormous amount of material was found, that another volume devoted entirely to pathogenic streptococci will be issued in 1928. The authors believe that there are hundreds of more or less definite varieties, and while they consider their work imperfect, have grouped approximately a hundred varieties in this volume.

Dr. Warren Crowe has devised a differential medium, which is expected to greatly aid in the differentiation of the many streptococci known to exist. About one-half of the work had been completed before Dr. Crowe took part in it. It is believed that the identification of all streptococci is beyond the power of any single individual.

This volume is indispensable for anyone pursuing this line of investigation. Twenty-one pages are devoted to bibliography, and about one-fourth of the entire volume is given to microphotographs, some of which are made from growths on Dr. Crowe's differential medium, and are colored. Descriptions accompany every photograph.

The volume shows an enormous amount of research, and we hope that some specially gifted person will make an abstract of it which the ordinary bacteriologist can utilize. In its present form it seems to us that it is suitable only for reference, and confess that the collection of this material does not clarify our ideas to any great extent. Since streptococci cause so much disease, death and misery to humans and animals alike, and as the editor states, "are the greatest and most dangerous of

mankind's invisible foes," no bacteriological study is more deserving of attention.

The volume on the pathogenic streptococci will be awaited with eagerness, and the two volumes will constitute the most important study made on this group of organisms which has yet appeared.

M. P. RAVENEL

This Smoking World—By A. E. Hamilton. New York: Century, 1927. 227 pp. Price \$2.50.

A. E. Hamilton is not a sanitarian nor does he write from special knowledge on the subject of tobacco. He accepts the orthodox majority viewpoint and expounds it in a humorous, whimsical style that calls forth no effort of intelligence to mar the reader's enjoyment. Tobacco, he feels, needs no defense. "The brief history of four centuries shows ample compensation for any physical harm tobacco may have done in the friendliness and fellowship which it has prompted among men." But he recommends that we smoke for enjoyment and not by habit. A "temperate practice" is, he admits, more difficult to form than an "automatic habit," but it is not impossible.

When the orthodox view has no scientific foundation, as in the case of juvenile smoking, Mr. Hamilton does not attempt to construct one, but after making fun of the reformers for their unproved assertions, he proceeds cheerfully to make another equally unproved one on his own account. "The use of tobacco," he says, "acts as a primary or contributory cause to a great deal of mental and bodily disturbance, amounting often to retardation and sometimes to pathological consequences." It is the accepted dogma and as juveniles are about the only class of people who do not contribute to the literature on tobacco, it is likely to remain so.

This Smoking World will appeal especially to the moderate smoker. He will

find justification for his habits, useful hints on the selection of cigars, and advice on the best way to take care of his pipe. The reformer will be frankly annoyed by the writer's levity. The scientist, though he will find diversion in an hour of leisure, will not find much else.

ROSSLYN EARP

The Harvey Lectures—*By various authors. Series XXII. Baltimore: Williams & Wilkins, 1928. 164 pp. Price \$4.00.*

The Harvey Lectures long ago won their place. The series for 1926-27 is fully up to the standard set in the past. While it may be invidious to select certain of them for special mention, we believe the first, fifth and sixth will be more generally interesting, largely because they come within the scope of the average man's training. The sixth lecture entitled "Organic Chemistry" gives a clear idea of the development of synthetic drugs and of chemotherapy. The lecture of Professor Neufeld is notable as a posthumous tribute to Koch, but shows surprising ignorance of American work. Among the 32 references, none is to an American author, and only 3 to English, yet we cannot but express the opinion that this country has for many years past held its own in this as well as other types of research.

M. P. RAVENEL

Bacterial Vaccines and Their Position in Therapeutics—*By Leonard S. Dudgeon, C.M.G., C.B.E., F.R.C.P. Lond. New York: Hoeber, 1927. 87 pp. Price \$2.50.*

We can commend most heartily this short book on the modern vaccine treatment of disease. It is notable for its saneness and conversativeness. Vaccine therapy has, we believe, come to stay, but has been injured by the misleading claims of manufacturers, and also by the undue enthusiasm of certain of its advocates.

The present book commends itself to the critical man by the absence of these faults. The author uses formalin to kill his cultures, and does not believe that sensitized vaccines are superior to others. He is convinced that the auto-genous vaccine is superior to the stock variety. He holds that vaccines have no place in the treatment of acute infections, and protests against their use in disorders, the etiology of which are unknown or indefinite, such as pernicious anemia, goiter, and chronic intestinal toxemia.

The book can be commended as eminently sane and practical. It is one of the series of Modern Medical Monographs, edited by Hugh Maclean, M.D., D.Sc., Professor of Medicine, University of London.

M. P. RAVENEL

Problems of Social Well-Being—*By James H. S. Bossard, Ph.D., New York: Harper, 1927. 654 pp. Price \$3.50.*

This book is one of the Harper Social Science Series, edited by F. Stuart Chapin.

The author states that it is the outcome of years of teaching university students such courses as social pathology, poverty and dependency, social maladjustment, etc. He finally discovered that three basic factors could be identified—economic, physical, and psychological—so that he finally formulated the idea that income, health and mental hygiene are the bases of social well-being. These he has emphasized, and discussed quite fully.

The book naturally falls into three parts, dealing with these three subjects, preceded by an introduction.

By far the largest part of the book is given to part II, which reads more like a history of medicine than a book on sociology, discussing as it does, the control of disease, immunity, the communicable diseases, nutrition, etc. The book is admirably written, and in spite of

some shortcomings which must be pointed out, we confess to much pleasure in seeing this type of work find its way into the hands of sociologists.

The book consists too largely of quotations, and largely from works written by men who have not had medical training; therefore certain things are emphasized incorrectly, or at least with doubtful accuracy. The reader is forced to suspect that the author has not properly digested his material.

A good deal of the material is old, and on that account, incomplete and incorrect. Sometimes instead of quoting from the original, second-hand information is given.

Calmette's vaccine against tuberculosis is spoken of only in regard to cattle and monkeys, though reports on several thousand children have been available for a year or more. The latest information on sanocrysine is a quotation now three years old, which states that it is a new and promising treatment, based "on principles which appear to be sound theoretically and successful in practice." In the meantime many experiments have been carried out, both in Europe and in this country, and the drug has been generally discredited. Some distinctly dangerous statements are made, as when the proper temperature for pasteurization of milk is given as 140° F. for 20 minutes. Not even those who are trying to lower the temperature below the widely accepted 145° F. for 30 minutes, ask so great a reduction.

When medical matters are treated of by a writer who is not a medical man, such things must be expected. The section on Mental Hygiene shows better consideration.

Altogether, the volume contains a large amount of reliable information, well thought out and well presented. We cannot help wondering why the author wandered into the discussion of certain cures which were not proved, instead of sticking to facts which were at hand. In a second edition, which the book deserves, such errors should be eliminated. We hope for the book a wide circulation among those who insist on talking about medical matters without having had adequate training.

The printing and binding are excellent, the paper being of medium weight with mat surface. M. P. RAVENEL

Sunshine and Health—By Ronald Campbell Macfie, M. B., LL. D. New York: Henry Holt, 1927. 256 pp. Price \$1.00.

This charmingly written little book is a volume of the Home University Library of Modern Knowledge. The chief criticism that one can make of it is that its title does not describe its contents. It contains a great deal of physics, history, philosophy and some religion. We confess that we do not quite understand what is meant by "the religion of radiation" or the "metaphysics of the sun."

The most practical part of the book is chapter IX, which treats of light therapy. The book can be commended for the vast amount of interesting information crowded into its 256 pages, though we believe that the average buyer will be disappointed if he depends upon the title.

It is excellently printed on light paper with mat surface.

M. P. RAVENEL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

The Physics of Light—A review of our knowledge and the theories of sunlight. Its therapeutic value is summarized.

ALEXANDER, F. W. The Value of Sunlight. *Med. Off.*, 30:14 (Apr. 7), 1928.

Alcohol Deaths—Are "alcohol deaths due to alcohol?" the author asks. The answer appears to be "yes," for papers following in the same issue show that the liquor samples tested contained no substances more toxic than "good" alcohol.

BIGELOW, G. H. Are "Alcohol Deaths" Due to Alcohol? *New England J. Med.*, 198:5 (Mar. 22), 1928.

School Ventilation—The amount of air per school child needed for proper ventilation (always without producing drafts) depends upon outside temperature. The inelastic standard of 30 cu. ft. per child per minute is not sufficient.

DUFFIELD, T. J. How Much Air Does the School Child Need? *J. A. M. A.*, 90:16 (Apr. 21), 1928.

The Nature of Bacteriophage—A comprehensive summary of the knowledge pertaining to the Twort-D'Herelle phenomenon, which suggests the theory that the bacteriophage is a principle emanating from the organism.

HADLEY, P. The Twort-D'Herelle Phenomenon. *J. Infect. Dis.*, 42:4 (Apr.), 1928.

Anti-Measles Goat Serum—Children exposed to measles in a hospital were found to be protected in a large percentage of cases by the serum of goats immunized to the diplococcus of Tunncliffe. The cases which did develop were attenuated.

HALPERN, L. J. The Prevention and Modification of Measles by Measles Antidiplococcus Goat Serum.

Use of Cod Liver Oil—An interesting account of the early rise and fall of cod liver oil therapy and the steps that led up to the recent reawakening of interest in this valuable preventive measure against rickets.

HARDING, T. S. A History of Cod Liver Oil Therapy. *Scient. Monthly*, (Apr.), 1928.

Early Diagnosis of Tuberculosis—A plea that medical students be taught adequately to diagnose and treat tuberculosis, to be taught to suspect tuberculosis. The education of the laity is also discussed.

HAWES, S. B. Suspecting Tuberculosis. *New England J. Med.*, 198:7 (Apr. 5), 1928.

Endamebic Dysentery—This paper summarizes the life history of the dysentery ameba and its effect upon the human organism. The importance of stool examination is stressed.

HUTCHINSON, H. S. Observations on Endamebic Dysentery. *J. Lab. & Clin. Med.*, 13:7 (Apr.), 1928.

Light Treatment Clinics—The author believes that carbon arc and mercury vapor lamps should both be installed in light clinics; the former for general baths, the latter for local treatments.

JOHNSTONE, J. Some Notes on a Light Treatment Clinic. *Med. Off.*, 39:13 (Mar. 31), 1928.

Ricinoleated Scarlet Fever Toxin—A study indicating that the supposed detoxifying effect of sodium ricinoleate is probably due to tissue destruction. The writer cautions against the use of ricinoleated toxin.

KOZŁOWSKI, A. The Effect of Ricinoleated Vaccine of the Hemolytic Streptococcus (Scarlet Fever) on Animals. *J. Immunol.*, 14:2 (Mar.), 1928.

Rural Health Service—A summary of county health organization in the United States during the years 1924-1928, revealing the fact that over 80 per cent of the rural population is still without adequate health protection.

LUMSDEN, L. L. Extent of Rural Health Service in the United States, 1924-1928. *Pub. Health Rep.*, 43:15 (Apr. 13), 1928.

Cancer and Smoke—A study of cancer deaths in Staten Island, N. Y., which suggests a direct relationship between cancer incidence and combustion products of coal and oil.

MEYERS, J. Cancer Death-Rate Variations in Relation to Combustion Products of Fuel, Topography and Population. *New York State J. Med.*, 28:7 (Apr. 1), 1928.

Reading Disability—A discussion of a clinical entity—inability to read not related to feeble mindedness. Examination methods and prognosis are included.

ORTON, S. T. Specific Reading Disability—Streptosymbolia. *J. A. M. A.*, 90:14 (Apr. 7), 1928.

Protection Against Streptococcus Infection—Two papers proposing the thesis that all hemolytic streptococci have a common pathogenic potentiality; and that scarlatinal streptococcus antitoxin will neutralize the toxin of all the hemolytic streptococci. Its use for all such infections is suggested.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Connecticut—The 41st report (49th year) of the Connecticut Department of Health for the fiscal year ending June 30, 1926, is bound in cloth covers and occupies 399 pages including a table of contents at the front and a subject index at the back. Good readable type, numerous illustrations in the form of photographs, statistical charts and tables are features. Individual reports from bureau heads are included, together with a report of a survey of the incidence of endemic thyroid enlargement in the State made in coöperation with the U. S. Public Health Service.

Commendable results in the child hygiene and public health nursing fields are reported. A plan for the extension of public health nursing to the communities where it is needed has been prepared whereby the state reimburses the smaller towns for a part of the cost of service. The plan is such that the town accepts it voluntarily if it desires the aid provided by the state.

Figures are presented to show what the state is losing from *preventable* deaths, the method of evaluation into dollars being that of the National Conservation Commission. According to this scheme an adult life is considered worth \$5,000, a child life from \$1,000 to \$3,000, and an infant, \$500. The averages for the periods 1915-19 and for 1920-24 are given, and a comparison is made with the situation in 1925. The majority of the diseases discussed show favorable balances. Under the heading of Savings Effected, the loss column shows that the state still has problems in influenza, venereal diseases, cancer, and diseases of the circulatory and nervous systems. It is calculated that the net savings represented by lessened deaths amounted in 1925 to over 3 million dollars. Total savings each year

since 1922 amount to over 11 million dollars. "Accounting of this sort cannot estimate the amount of time or wages lost on account of preventable sickness. However, it may safely be said that with improvement in preventable deaths, some savings must be made in preventable sickness. Connecticut has had another favorable year."

Middletown, N. Y.—An illustration of an attractive, dignified, but inexpensive annual report, is that of Middletown, N. Y., for 1927. A brief review of public health trends and of local problems precedes the account of the year's work. "Large sums are spent in drives for better business, teams are organized to canvass the city, but what does this avail if we do not have healthy citizens, with earning capacity and buying power? Our two years without a case of diphtheria are not noticed by business, but how business would sit up and take notice if we had 80 cases at one time—which is the record of a little more than a decade ago!"

The diphtheria immunization work has been noteworthy. At present, as each birth certificate is filed, a card for it is indexed so that when the baby reached 6 months of age its parents receive a request to have it protected either by the family physician or the health department. A monthly mimeographed bulletin is distributed, briefly stating the health condition of the city and of the surrounding section. New activities of the board, and a short article on some timely health subject are also included.

Pittsburg County, Okla.—The 3rd annual report of the Pittsburg County Coöperative Health Unit for the fiscal year ending June 30, 1927, indicates

the benefits of organized county health service. The personnel for this county of 52,000 people consists of a medical director, a nurse, a sanitary inspector and a secretary. The area covered is 1,370 square miles. There are 136 schools with a total enrollment of 10,000. It is stated that much progress has been made in sanitation throughout the county, especially in the small towns. This work has included improvement in dairy conditions as well as in the installation at schools and private homes of sanitary conveniences. During the three years that the Unit has been active, 5,059 persons have received complete anti-typhoid inoculations. "In reality the typhoid cases in the county proper show a decrease of 50 per cent." Maternity and infancy work has gradually increased. A large per cent of the women are of foreign nationality and difficult to reach. This work consists of group conferences as well as office consultations. During the year, in connection with the child hygiene work, 146 lectures have been given with an attendance of over 6,000 persons, while 4,326 children have been examined.

Kansas—The 41st and 42nd annual reports of the State Board of Health of Kansas for the periods ending July 1, 1926, indicate that no unusual epidemics prevailed during the biennium. In 1925, a new low death rate from diphtheria was recorded, 3.5 per 100,000 population. During the fiscal year 1926, 10 Kansas counties operated under a full-time health administration plan, in coöperation with the U.S.P.H.S. and the Rockefeller Foundation. The report abounds in detailed statistical tables and graphs with descriptive text. One noteworthy feature is a brief comparison of full-time and part-time county health units in Kansas. "It is found also that wherever a full-time, active, competent county health officer is appointed, he lowers the infant mortality promptly

and speedily accelerates the diminution of the death rate from tuberculosis. He engages in effective measures for the education of the public in health matters and generally succeeds in a striking manner in increasing the span of life of those who reside in the community which he serves."

Delaware—The State Board of Health report for the two-year period ending June 30, 1926 is bound in cloth covers and occupies 150 pages. During this period a full-time director of tuberculosis work has been added to the staff; a medical director of child hygiene was appointed; the laboratory has been moved to Dover, and newly equipped; new legislation was passed; and a successful campaign for diphtheria prevention was inaugurated. Two noteworthy features of the report of the secretary of the board are a list of recommendations regarding new legislation, and a tabulation of office activities, including the number of letters, records, and reports received. By such tabulations, it is possible to formulate an impression regarding detailed routine activities, which are often important as well as time-consuming. A financial statement, classified as to functions, precedes the body of the report.

Child health conferences were conducted in 18 health centers. A motor truck is also used for itinerant clinics throughout the state. Of the 44,361 children reached by the Bureau, 14,313 were preschool, and 3,184 infants under one year of age. Excellent photographs of the clinics, sanatoria and laboratory are published.

Regular inspections were made of oyster plants and samples are taken from the various oyster shucking houses, from the beds on which oysters are grown, and from the water above the beds. Examinations were made of all employes to determine whether they were carriers of typhoid fever. The

plants were certified by the State, the certification being approved by the U.S. P.H.S. and forwarded to the oyster shucking plants.

Newark—Newark's 42nd annual report of the department of health has several noteworthy features. Preceding the main report is a page headed Newark—A Healthy City, Outstanding Evidences in 1926. Here are given the population and vital statistics data. Then follow pages giving a table of contents, a brief health officer's statement, and the organization and personnel of the department. The report is printed in good readable type and contains several excellent statistical graphs to illustrate the text. A classified financial statement shows the total disbursements through the health department of this city of 460,000 population to have been \$419,771.

An adjusted death rate of 11.1, and a birth rate of 22.7 per 1,000 population are recorded, with an infant mortality rate of 71.9. The specific death rate from typhoid was 1.5; from tuberculosis (all forms), 91.5; from diphtheria, 4.6, and from scarlet fever, 1.1 per 100,000 population. Rabies is said to be increasing, and the advantages of inoculation are detailed. Accidental deaths during 1926 numbered 304, representing a decrease of 39 over the previous year. Organic heart disease was the leading cause of death (984), followed by pneumonia, (675), cancer (498) and pulmonary tuberculosis (368). Death rates from all causes and from certain special causes are tabulated for each year beginning with 1894. Infant mortality is analyzed according to color, age and cause. It is interesting to note that the infant mortality rate for infants supervised by the Child Hygiene division was 60.3 (27.0 under 1 month) as compared

with a rate of 78.9 (40.4 under 1 month) for infants not supervised by the Division. Reports from each division of the department are included and serve to make a very readable volume.

East Harlem, N. Y.—An interesting report of a vital statistics study bears the title: Casting the Life Lines for East Harlem. This study, following a period of approximately 5 years' work of the district health center, is presented as an index for measuring the effectiveness of coördination and intensive health endeavor. This district includes 8 sanitary areas comprising 87 city blocks, with an area of 4½ acres and a population of approximately 108,000. An encouraging part of the picture is the improvement shown in the majority of the areas of the district. In 1925, five of the areas had a general mortality from 3 to 5 points below their rate in 1920, from 1 to 3 points below the city's 1925 rate, and from 4 to 6 points below Manhattan's. The lowest death rate (9.03 per 1,000 population) appeared in an area where an intensive nursing and health demonstration has been conducted since the beginning of 1923. Marked improvements are noted for pneumonia and for diarrhea and enteritis. The general mortality rate for the 5 year demonstration period was 18% lower than that of the 5 year pre-demonstration period. Detailed statistical tables and graphs form a valuable part of this report.

"Obviously the life lines in East Harlem are being strengthened and lengthened.—This study of vital statistics is one more bit of evidence that coördination of the work of health and welfare agencies and intensive health service administered according to a district plan will definitely improve the health conditions of a community."

NEWS FROM THE FIELD

CONFERENCE ON LIGHT AND HEAT

AN invitation has been extended to all American doctors by the *British Journal of Actinotherapy* to attend the 2nd International Conference on Light and Heat in Medicine, Surgery and Public Health, which will be held in London, England, October 29-November 1, 1928. The University of London will be conference headquarters. There will be an exhibition of the most up-to-date apparatus and accessories for ultra-violet, radiant heat and kindred forms of therapy. Several well-known English and Continental specialists will lecture and take part in the various technical sessions. Visits to representative clinics will be arranged to give delegates to the Congress an opportunity to see the methods of utilizing the light and heat for therapeutic purposes.

LOS ANGELES HELPS IN FLOOD AREA

THE Los Angeles County Health Department, under the direction of Dr. John L. Pomeroy, health officer, has assumed full sanitary control of that portion of the flooded area in Los Angeles County affected by the breaking of the St. Francis dam. Dr. Pomeroy's force is reported as having done excellent work in safeguarding the health of the residents in this area and having accomplished thorough and quick results in providing for the sanitation in the county.

NORTHERN CALIFORNIA PUBLIC HEALTH INSTITUTE

THE Northern California Public Health Association is holding a Public Health Institute, May 29-June 8. Sessions will be held daily from 3 to 4:30 in the afternoon, and each evening from 7:30 to 9 o'clock. The afternoon

sessions will be primarily for professional people such as teachers, nurses, health officers, bacteriologists, social workers and other interested public health employees. The evening sessions will be open to the general public and will be of general interest. Dr. Haven Emerson of Columbia University, New York, N. Y., will conduct the Institute.

CANCER SOCIETY OFFERS PRIZE FOR POSTER

IN coöperation with the Art Alliance of America, the American Society for the Control of Cancer has offered cash prizes of \$500, \$250 and \$100 for the best poster designs for use in its cancer campaign.

Particulars may be obtained on application to the New York City Committee of the Society, 34 East 75th Street, New York, N. Y.

HEALTH EDUCATION SCHOLARSHIPS FOR WOMEN

THE Massachusetts Institute of Technology, through its Department of Biology and Public Health, has announced the establishment of two full tuition scholarships for women in the field of health education—one or both of these scholarships to be awarded on or before the last day of July, 1928, according to standards and procedures arranged by the Scholarship Committee and the Department of Biology and Public Health. The amount of each is \$400.

NATIONAL LEPER HOME AT CARVILLE

ACCORDING to a recent report by Surgeon General H. S. Cumming of the U. S. Public Health Service, there were 56 lepers admitted to the hospital at Carville, La.; 12 patients were readmitted and 2 were discharged on parole,

as their leprosy was arrested, so that they were no longer considered a menace to the public health. There were 17 deaths there last year.

It is of interest to note the nativity of the 278 patients now at this hospital. They come from 20 states and 3 United States insular possessions. Louisiana, Florida and Texas lead the states furnishing patients and twenty-four foreign countries have sent patients.

IMPROVEMENTS ON INDIAN RESERVATIONS

AN agreement has been reached between the Office of Indian Affairs of the Department of the Interior and the U. S. Public Health Service of the Treasury Department, whereby certain sanitary engineer officers of the U. S. Public Health Service will assist the Bureau of Indian Affairs in connection with pure water supplies, proper and adequate sewage disposal, and other sanitary improvements on many of the Indian reservations and at various Indian schools, throughout the country. This will obviate the necessity of the Office of Indian Affairs building up its own force of sanitary engineers, or having to procure such assistance from outside sources.

During the past year a number of surveys were made by Sanitary engineer officers of the U. S. Public Health Service in connection with improvements at several Indian Reservations. On the basis of these surveys, appropriations were asked from Congress for the installation of new water systems and sewage disposal systems on several of the reservations surveyed.

77 PER CENT OF TEACHERS RETIRE BEFORE AGE 55

A record of the ages of 357 New York State public school teachers retired on pension during the past 6 years because of disability shows that 276 or over 77 per cent were retired before the age

of 55, according to Dr. William A. Howe, State Medical Inspector of Schools. Only a small group of 19 (5.3 per cent) retired after they had reached the age of 60. Discussing the report Dr. Howe said:

These figures clearly indicate that a vast majority of teachers fail in health at a period of their lives when senile changes are as a rule not operative. They impress us with the great loss, much of which by proper health teaching is preventable, that the teaching profession is each year suffering. They still further emphasize the need as well as the opportunity . . . and duty, of systematically aiding teachers to more carefully safeguard their health.

GEORGIA HEALTHMOBILE

THE fifth annual health tour of the Georgia State Board of Health's "healthmobile" opened April 9 and will close November 7.

COMMUNITY HEALTH MEETING

THE Allegany-Garrett County Medical Society and the health department of Cumberland, Md., sponsored the fourth annual community health meeting on May 10, at the state armory, Cumberland. The speakers were: Senator Royal S. Copeland, New York, N. Y.; Morris Fishbein, M.D., Chicago, Ill.; and James Hall Mason Knox, Jr., M.D., Maryland Health Department.

DELAWARE INSPECTS TOURIST CAMPS

DELAWARE health authorities have taken the initial steps for the protection of health of campers, tourists and vacationists who may stop in the state, by demanding that operators of summer or tourist camps file applications for permits to operate such camps, so that inspection of the sanitary and health conditions can be made immediately. John S. Fulton, M.D., director of the State Department of Health has announced that to be duly certified each camp must satisfy the requirements of the State Board of Health as to protection of water supplies from pollution;

disposal of sewage; protection of food supplies from contamination, and general cleanliness. A licensed camp will be given a placard bearing the state seal and the statement, "This camp has been inspected and approved by the State Board of Health."

DR. DAVIS DIRECTS VITAL STATISTICS OF TEXAS

W. A. Davis, M.D., formerly city health officer of Fort Worth, Tex., has been appointed director of the Division of Vital Statistics of the Texas State Department of Health.

Dr. Davis at one time served as health officer of Atascosa County, Tex. He has also served as State Registrar of Births and Deaths, Secretary of the Texas State Board of Health and at one time was Director of the Bureau of Vital Statistics in Georgia.

TOLEDO PUBLIC HEALTH ASSOCIATION

THE Toledo Public Health Association and its affiliated agencies, through legislation, has obtained the appointment of a full-time health officer. Dr. Paul F. Orr has received the appointment of Commissioner of Toledo on a full-time basis. Dr. Orr was formerly associated with the Michigan State Department of Health.

CANCER CAUSES GREAT ECONOMIC LOSS

CANCER in 1927 was responsible for a monetary loss of about \$800,000,000, according to a recent announcement made by Louis I. Dublin, Ph.D., Statistician, Metropolitan Life Insurance Company. This represents an economic loss as great as if 300,000 workingmen had been idle for a year. Dr. Dublin also stated that \$680,000,000 represents the monetary cost of persons dying from cancer, and that \$110,000,000 was spent in caring for the victims. He is of the opinion that the current year will undoubtedly see

a greater economic loss and a greater amount of suffering, since cancer is on the increase.

DR. MASON JOINS ROCKEFELLER FOUNDATION

PRESIDENT Max Mason of the University of Chicago has resigned to become head of the newly created Division of Natural Sciences of Rockefeller Foundation, New York, N. Y. Dr. Mason was elected president of the University of Chicago in August, 1926, to fill the vacancy caused by the death of President Ernest de Witt Burton.

INSTITUTE ON SOCIAL HYGIENE

A SOCIAL Hygiene Institute will be held at the Chautauqua, N. Y., July 9 to August 17, under the direction of the American Social Hygiene Association in coöperation with New York University, Chautauqua Institution and the Chautauqua Summer Schools. The courses to be given by Dr. Thomas W. Galloway and Newell N. Edson will be credited as two points by New York University.

The titles of the courses are "Sex and Education," "Special Problems in Social Hygiene," "Interpreting the Family to Children," and "Parenthood and the Character Training of Children." This is the third annual institute held by the A. S. H. A. at Chautauqua.

COLLEGE TO COÖPERATE WITH STATE

AMONG the recommendations made in the recent survey report on higher education in relation to the Medical College of Virginia at Richmond are that the college take over the state public health laboratory now maintained by the Virginia State Board of Health and that the school of nursing be more generously developed on the side of pediatrics and obstetrics, to make possible more affiliations in these subjects with the smaller hospitals of the state.

PERSONALS

- DR. FRANCIS D. COMAN of Johns Hopkins University Hospital, Baltimore, Md., has been chosen medical officer to accompany Commander Byrd's expedition to the South Pole.
- DR. ALFRED C. REED, a former member of the faculty of Stanford University, has been appointed Professor of Tropical Medicine in the Hooper Foundation for Medical Research, University of California. This announcement was made by President William W. Campbell of the university. Dr. Reed is at present studying at the London School of Tropical Medicine.
- DR. JAMES J. DURRETT, Memphis, Tenn., has succeeded Dr. George W. Hoover in charge of the Food, Drugs and Insecticide Administration, U. S. Department of Agriculture. Since 1920, Dr. Durrett has been city supervisor of health in Memphis and professor of public health at the University of Tennessee.
- DR. J. C. ANDERSON, State Health Officer and V. M. Ehlers, Chief Sanitary Engineer, Texas State Board of Health, attended the first short school for Sanitarians recently held at Tuscon, Ariz., under the direction of the state health officer and Jane H. Rider, director of state laboratories.
- C.-E. A. WINSLOW, Dr. P. H. of Yale University has been awarded the Ling medal by the Ling Foundation of Los Angeles, Calif. in recognition of his "unselfish work in behalf of the health progress of school children."
- DR. ANNA EARL PURDY, an intern at the Norwegian Hospital, Brooklyn, N. Y., is the first woman physician to be awarded a three year surgical fellowship at the Mayo Foundation, Rochester, Minn. Her work starts in October of this year.
- DR. EDWARD L. KEYES has been appointed consulting urologist to the State Department of Health in New York State.
- DR. MALCOLM IRVINE has been appointed health officer of North Powder, Ore.
- DR. ABRAHAM METZ, city chemist of New Orleans, La., has been forced to resign that position because of ill health. He has held this position for 36 years.
- DR. PAUL H. MEANS, Cambridge, Mass., has been appointed medical adviser to Harvard University to succeed Dr. Marshall H. Bailey.
- DR. FRANCIS D. DONOGHUE has accepted the appointment as representative of the United States at the Fifth International Conference for Medical Science as applied to workmen's accidents and occupational diseases, to be held at Budapest, Hungary, in September.
- DR. FREDERICK L. WEBBER has been appointed police surgeon of St. Paul, Minn.
- DR. JOHN J. TOPHAM, South Berwick, Me., has accepted the appointment of university physician in the University of New Hampshire, Durham, N. H., to succeed the late Dr. Nathan L. Griffin.
- DR. FRANCIS S. FERRIS, Glenside, Pa., has been appointed chief medical examiner for the Philadelphia and Reading Relief Association, to succeed Dr. Casper Morris, resigned.
- GEORGE H. CRAZE, field representative of the Texas Public Health Association has resigned to become executive secretary of the Texas County Public Health Association with headquarters at San Antonio. This organization is affiliated with the Texas Public Health Association and the National Tuberculosis Association.

DR. DANIEL CONNELLY, health officer of Kingston, N. Y., since July 1923, died on March 22, after a week's illness.

DR. FRANK L. KELLY of Oakland, Calif., relinquished his position as health officer on April 1, to take over the duties of health officer of Berkeley, replacing Dr. James R. Scott.

DR. FANCHER is the new health officer of Oakland, Calif.

DR. FRANK R. WOOD, Heflin, Alabama, has been appointed health officer of the new Cleburne County health unit.

ERNEST L. WALKER, Sc.D. of the University of California Medical School has just returned from a 14 months' stay in Honolulu, where he carried on investigations as to the cause of leprosy at the invitation of the U. S. Public Health Service.

DR. ALBERT L. MORGAN has resigned as health officer of Dexter, N. Y., where he has held this position for more than 35 years.

DR. JOHN N. SHUMWAY has completed his 30th year as health officer of Painted Post, Steuben County, N. Y.

DR. GEORGE R. ALBERTSON who has been acting dean of the school of medicine of the University of South Dakota for two years, has been appointed to the position of dean, to succeed the late C. P. Lommen.

DR. EUGENE DAVIS has assumed charge of the U. S. Veterans' Bureau Hospital No. 88 at Memphis, Tenn.

DR. GUY W. HENIKA, Madison, Wis., has been appointed assistant state health officer of Wisconsin.

DR. ROBERT L. FRISBIE, Humbird, Wis., has been appointed deputy state health officer.

BERNARD C. ROLOFF, formerly superintendent of the Illinois Social Hygiene League of Chicago, is now in charge of the Department of Publicity and Publications of the City Health Department of Chicago. Mr. Roloff has also accepted the position of execu-

tive secretary of the Chicago Boy's Federation, and is now busily engaged in preparations for their big exposition and celebration to be held the week of May 21-28.

DR. F. R. SMYTH, director of Bureau of Communicable Diseases of the North Dakota State Department of Public Health, Bismarck, N.D., died recently.

DR. ADOLPH J. LIEBER has been appointed health officer of the city of Des Moines, Ia.

DR. VICTOR H. HASEK has been appointed health officer and city physician of Cedar Rapids, Ia.

DR. ALDO CASTELLANI recently completed a series of lectures on tropical medicine in Madrid, Spain, under the auspices of the Royal Academy of Madrid at the invitation of the Queen of Spain.

HOMER FOLKS, secretary of the State Charities Aid Association, New York, N. Y. was awarded the service medal of the Rotary Club of New York at a recent meeting of this club with the State Conference on Crippled Children.

DR. GEORGE EMMETT BETHEL, director of the university health service of the University of Texas, has been appointed by the board of regents of the university, as dean of the state medical college, Galveston.

POSITIONS WANTED

Services of thoroughly qualified graduate sanitarian soon will be available. Experienced in state and municipal public health work, housing, sewerage and sewage disposal, social surveys, municipal waste collection and disposal, sanitary inspections, reports, investigations, etc. Excellent at organization and administration. Let's get together and talk it over. Address 50 W. F.

DIRECTOR OF LARGE PUBLIC HEALTH LABORATORY desires change of position. College graduate. Has organizing and administrative ability. Trained and experienced in all forms of laboratory procedure. Address 52 M. C.

HEALTH OFFICER, trained and experienced in epidemiology, venereal diseases, immunization, chemistry, bacteriology, school hygiene, sanitation and vital statistics desires larger opportunity. Young, congenial and with good health. Address 55 H. D.

NEO-SILVOL

Practically Non-Staining

For local infections of accessible mucous membranes try Neo-Silvol, a colloidal silver iodide that is daily gaining in favor with discriminating physicians. Neo-Silvol is peculiarly adapted for this purpose because it does not stain the skin, mucous membrane, or linen with which it comes in contact; because it causes neither pain nor irritation to sensitive tissues; and because it has a selective action against certain bacteria which makes it even more effective than carbolic acid. For gonorrheal infections it is particularly appropriate: it is twenty times as strongly germicidal as pure carbolic acid.

Neo-Silvol is supplied in 1-oz. and 4-oz. bottles of the granules; in 6-grain capsules, bottles of 50, as a 5 per cent ointment in 1-drachm tubes; and as 5 per cent Vaginal Suppositories in boxes of 12

Literature will be promptly mailed on request

PARKE, DAVIS & COMPANY

Bacillus Calmette-Guérin (B.C.G.)

Animal Experimentation and Prophylactic Immunization of Children

An Analysis and Critical Review

S. A. PETROFF, Ph. D., and ARNOLD BRANCH, M. D.

Research and Clinical Laboratory of the Trudeau Sanatorium, Trudeau, N.Y.

THE feverish enthusiasm manifested in the wholesale antituberculosis vaccination in European countries, and mainly in France, has accomplished one very good purpose. It has administered a stimulus to the stagnant question of prophylactic immunization.

The literature on B.C.G. vaccination is rapidly accumulating. Nearly 100,000 infants have been treated by this method. It is surprising that only a small number of them have come up for a statistical study. The favorable results reported have been gained largely from impressions and not from facts. On account of the many inquiries which have come to our attention the present review has been written.

The gradual decline year after year in the mortality from tuberculosis as shown by reliable statistics, is the best index that the campaign adopted years ago is sound and effective. This campaign has also influenced the death rate due to other causes, with the exception of heart disease and cancer. Education, sociological activities and various health measures stimulated by prosperity have played an important part in the improvement of living conditions and in the prolongation of life. However, this decline of mortality from tuberculosis has in no way influenced the investigator to discontinue his search for a method which can be safely used for vaccinating children against tuberculosis.

Attempts at prophylactic immunization against tuberculosis date from the time of the discovery of the microörganism. Koch, Pasteur, Trudeau, Dixon, Maragliano, Pearson and Gilliland, Theobald Smith, Calmette, Römer, Baldwin, Webb and Williams and many others have tried to devise some method which could be used safely for this

purpose. Many methods have been studied and recommended. The methods which most demand our attention today are three: Vaccination with (1) virulent living, (2) avirulent living, and (3) heat-killed virulent tubercle bacilli. In the following pages the discussion will be limited to the method advocated by Calmette and his coworkers, which consists of vaccination with avirulent living organisms.

PREMISES ON WHICH CALMETTE'S METHOD OF VACCINATION ARE BASED

The prevalence of tuberculous infection among children in the civilized world, as demonstrated by the tuberculin skin test, varies considerably. Hamburger and Monti¹ in Vienna reported 94 per cent positive reactions in children at the age of 12 years. In rural districts in Germany, Römer² found 66 per cent of the children to be infected at the age of 11. Very similar findings have been reported by S. Mueller³ in Berlin, Moro⁴ in Munich, Petruschy⁵ in Dantzig and Northmann⁶ in Dusseldorf. In Paris 35 per cent of apparently healthy children up to the age of 5 give a positive tuberculin reaction. Arnfsen⁷ studying 8000 children of various ages observed a positive reaction in 33 to 38 per cent. In the United States the incidence of infection detectable by the tuberculin reaction is not so great as that reported in European countries. Veeder and Johnston⁸ in St. Louis observed a positive tuberculin reaction in 44 per cent of children from the ages of 10 to 14. Some children with clinical disease were included in this group. Slater⁹ studied two groups of children in Minnesota: The first with no history of exposure reacted positively in 10 per cent, and the second who were living in tuberculous surroundings reacted positively in 80 per cent. Myers and Magiera¹⁰ reported 41 per cent in a study of 2000 children in Minneapolis. Still¹¹ in a group of 58 children with no history of tuberculosis and living in the lower East Side of New York City, observed only 9.8 per cent positive Pirquet tuberculin reactions.

The foregoing figures reveal the fact that by the time children reach the age of puberty, from 40 to 90 per cent may have become infected, the social and economic conditions mostly influencing the percentage of infection.

Let us for a moment examine the statistics of early infant infection which have stimulated the present activities for prophylactic immunization. McLean and Jeidell¹² examining 2000 infants under 1 year of age found a positive infection in 7.35 per cent, while in a second group of 512 children of 3 years of age it reaches 32.5 per cent. Spolverini¹³ found 7 per cent positive reactions in a study of 900 infants of the same age, Sander¹⁴ 6 per cent up to 2 years, and Armstrong¹⁵ 15 per cent for the same period. In New York City, Drolet's

studies²⁶ reveal that from 10 to 12 per cent of all children become infected with tubercle bacilli before they reach 1 year of age. Taking the birth rate of 1923 when 130,000 infants were born, he calculates that in all probability 13,000 of these children became infected during the first year of life.

If we now turn our attention to the study of possible infection in children brought up in a family with a history of tuberculosis, the occurrence of the positive tuberculin reaction is materially increased. Harms and Seitz²⁷ studying 129 infants under 1 year of age reported 60 per cent positive tuberculin reactions, Röpke²⁸ 67.5 per cent and Barchetti²⁹ 73 per cent. The mortality from tuberculosis in the first year of life, after infection has occurred, appears to be very high. Brown³⁰ reports 70 per cent, Hemplemann³¹ 78 per cent, Davis³² 45 per cent, Reuben and Smith³³ 68 per cent, Lemaire³⁴ 57 per cent, Harms and Seitz³⁵ 23.9 per cent, Lozano³⁶ 26 per cent, and Wahlquist and Myers³⁷ 8.4 per cent. Petersen and Ostenfeld of Denmark, as quoted by the *British Medical Journal*³⁸ give only 6.2 per 1,000, while the same authors quoted by Calmette³⁹ give 7.7 per 100.

From these brief statistics it seems that infants are born with no appreciable resistance to an excessive infection. If they are born in families in which the tubercle bacilli are disseminated continuously, infection will probably take place almost immediately. Excessive infection takes place more often from contact with a tuberculous mother, and in the majority of instances a progressive disease is the result, which may later lead to meningitis or miliary tuberculosis. On the other hand, if the infant comes in contact with only a few organisms and at proper intervals, it may escape serious consequences.

Under ordinary circumstances, and not in tuberculous surroundings, without doubt children occasionally pick up a few organisms which find their way to the lymph nodes, setting up a small, non-progressive focus which according to the majority of investigators is responsible for a degree of resistance to progressive disease present in the human race. Statistics show that the percentage of positive tuberculin skin reactions increases with age, and conversely the mortality from tuberculosis diminishes as the child becomes older. It seems then, according to Calmette,⁴⁰ that in humans as in animals, an infection of mild nature is very desirable. The excessive infections must be avoided and the intervals well regulated. The organism used for producing mild infection should be of low virulence and the vaccination must be carried out in infants which have not been infected. The vaccination must be repeated from time to time in order to supply the lymph nodes with living organisms.

Calmette²² is convinced that most of the infection in children takes place by the digestive route, for the reason that the intestinal mucosa of the infant during the first 10 days absorbs the organism much more readily than at any other time during life. If, according to this author, the infection takes place through the intestinal tract, then the same route must be used for vaccination. For this reason and also because of its simplicity, all Calmette's vaccinations have been carried on by feeding the organism to new-born babies. Two factors enter into the discussion when the method of vaccination is based on the use of living microorganisms: (1) Is it dangerous? (2) Is it effective?

I. PATHOGENICITY OF BACILLUS CALMETTE-GUÉRIN (B.C.G.)

The organism was isolated by Calmette and his associates in 1908. It was a bovine organism originally of moderate virulence for guinea pigs, rabbits and cattle, but after continuous cultivation on glycerinated potato bile medium it has lost its power of producing generalized tuberculosis, not only in cattle but also in small laboratory animals. Even in 1913 we find some reference that after 30 to 34 passages on this medium the organism had lost some of its pathogenicity. The authors claim that the environment and the medium have played a great part in the change. In an earlier publication Calmette and his coworkers claimed that the organism did not form tubercles or set up a tuberculin hypersensitiveness. Later they amended this statement in answering some of the objections made on the pathogenicity of this organism. We shall briefly review some of Calmette's experiments."

When the organism was injected into the cellular tissue of the dewlap of newly born calves, it did not disseminate as in the case of a virulent organism, but remained localized at the site of inoculation for a year. Abscesses aspirated revealed acid-fast rods, which were not capable of infecting guinea pigs on subinoculation.

Subcutaneous inoculations of 3 mg. in guinea pigs and rabbits produced very slight, localized lesions in the form of small nodules which disappeared after 2 to 3 weeks. When 5 to 10 mg. were inoculated, edema developed on the following day. Within 10 to 12 days a small abscess appeared at the point of inoculation, breaking externally and suppurating from 2 to 4 weeks and then cicatrizing. The regional lymph nodes became enlarged but not caseous and soon they subsided to normal size. Excessive doses from 100 to 150 mg. after 2 to 4 weeks produced small granular follicles in the spleen, which disappeared in the course of 2 months. When suspected tissues were triturated and inoculated into a second series of animals no progressive disease was noted. However, very often when guinea pigs were inoculated with

doses of 50 mg. or more, many became emaciated and died. Many tuberculous-like changes were present in the viscera but these authors claim that the changes were due to pseudotuberculosis. from which *Bacillus pseudotuberculosis rodentium* was isolated.

Intraperitoneal inoculations of small doses were well tolerated. Three mg. produced nodular reactions in the omentum. Later these nodules increased in size and persisted for 6 months and then completely disappeared.

Intracardiac and intravenous inoculations of 1 to 10 mg. had no ill effects in guinea pigs and rabbits. In about 15 days the lymph nodes at the groins became swollen and remained so for 10 days. This swelling completely disappeared in a few months. In the animals killed at the height of this reaction, the liver, spleen and lungs usually showed follicular lesions which were visible to the naked eye.

Administration per os was well tolerated, even in doses up to 100 mg. After 2 to 3 weeks following the feeding there was a general glandular enlargement, especially in the mesenteric lymph nodes. If the animals were killed during this period, small follicular lesions were found in the viscera and the tracheo-bronchial lymph nodes contained many acid-fast bacilli. All these lesions showed no tendency to progress, and gradually disappeared.

Direct intrapulmonary inoculations of 10 mg. of B.C.G. in half of the animals formed small, deep-seated abscesses. These abscesses were well borne by the animal and never culminated in death unless a superinfection of Pasteurella organisms occurred. In animals which survived 8 months the abscesses containing many acid-fast organisms were still present. In no instance were these authors able to transfer the suspected tuberculous lesions into a second series of animals, nor to increase the virulence of the organism.

Remlinger and Bailly,³¹ Kühn,³² Tzekhnovitzer,³³ Gentili, Gerosa, Mangiarotti, Nai, Setti, Zotini and Bassi,³⁴ Okell and Parish,³⁵ and others have confirmed Calmette's observations. However, there is a group of investigators including R. Kraus,³⁶ Selter and Blumenberg,³⁷ Gerlach,³⁸ Nobel,³⁹ Chiari, Nobel and Sole,⁴⁰ who have been able to produce lesions in guinea pigs and in some instances progressive disease leading to the death of the animal.

The organism is non-pathogenic for monkeys according to Wilbert,⁴¹ who inoculated a number of chimpanzees, baboons and other types of monkeys. All tolerated very well even 100 mg., per os or intravenously. Subcutaneous inoculation produced slight edema with persistence of painless induration. Animals dying from intercurrent disease showed no evidence of tuberculosis.

OCCURRENCE OF TUBERCULIN REACTION IN ANIMAL EXPERIMENTATION

The development of the tuberculin reaction depends on the mode of inoculation. By ingestion a small number of animals become allergic. The same has been the result by the intravenous route. Nélis⁴ states that tuberculin skin hypersensitiveness appears in adult guinea pigs between the 1st and 2d months and lasts from 6 to 10 months after ingestion of B.C.G.

Tzekhnovitzer⁵ claims that guinea pigs become hypersensitive to tuberculin after treatment with B.C.G., the highest intensity occurring from 2 to 4 months. Seventy per cent of those infected orally and 45 per cent of those infected by the subcutaneous route react. The intraperitoneal and intracutaneous inoculations apparently do not sensitize animals to tuberculin. Rabbits do not react very readily to tuberculin after treatment with B.C.G. organisms. The ophthalmic reaction, however, is positive in 100 per cent of all animals.

Bruno Lange⁶ obtained positive reactions to tuberculin in 100 per cent of guinea pigs inoculated intravenously, in 80 per cent of those inoculated orally and in 62 per cent after inhalation.

In regard to phagocytosis, Metalnikov and Secreteva⁷ noticed that the cellular reaction is very similar to that observed in animals infected with virulent organisms.

II. IMMUNITY IN ANIMALS VACCINATED WITH B.C.G.

Calmette⁸ and his coworkers claim that intravenous inoculation of 25 to 30 mg. of the organism in a fine suspension will protect rabbits against 0.001 mg. bovine bacilli which kills controls in 75 days. This resistance began to diminish in about 6 months, after which the lesions due to the virulent bovine infection progressed very rapidly, causing the death of the animal. Subcutaneous and intraperitoneal sensitization was not very effective. Rabbits of 15 to 20 days of age when sensitized by the buccal route by making them ingest organisms dropped with a pipette, resisted subsequent infection of a virulent organism very much like those vaccinated intravenously. If they were inoculated 3 months after the B.C.G. vaccination with a virulent bovine culture, the sensitized animals outlived the controls by 6 months and at autopsy only discrete lesions could be seen.

Guinea pigs were not so suitable for immunization for the reason that they are extremely susceptible to intercurrent infection. The adult guinea pig, following a single intracardiac inoculation of 5 to 10 mg. or by two subcutaneous inoculations of 50 mg. at 2 months-interval, shows considerable resistance to an infecting dose of 0.001 mg. Or still better,⁹ if very young guinea pigs of 8 to 20-days of age are

given ten feedings of 100 to 150 mg. of the organism with a pipette at 20 hours-intervals, they will resist 0.001 mg. of a virulent culture. The infecting dose may be given either by intraocular instillation of a drop of fine emulsion or may be fed to young guinea pigs. In both instances, according to these authors, the results are very satisfactory.

Guérin, Richart and Bossière⁴ studied a large number of cattle on a farm where the latter were raised for the production of butter. On this farm in 1915, in a herd of 67 head, 47 per cent reacted positively to the tuberculin test. Year after year the reactors were slaughtered. This procedure was not effective in completely eradicating tuberculosis from the farm. In 1919, 38 per cent were still positive to the tuberculin test. In 1920, the number of reactors was increased to 41.7 per cent. Vaccination in the new-born cattle started January 1, 1921. No special precaution, according to the authors, was taken to eliminate the possibility of contamination. In 1922, one year after the vaccination, 20 cattle gave a definitely positive and 9 a very suspicious tuberculin reaction, or a total of 45 per cent of 64 head. Many of those animals were vaccinated and revaccinated. In 1923, there remained 26 of the 1919-20-year animals, all giving a positive tuberculin reaction. In 1924 only 5 reactors were allowed to live with the young vaccinated animals. In 1925, only 2 remained of the original 1919 animals, 3 having been killed. In 1 of the 3 reactors killed, no tuberculosis could be found, in the 2d there were only few tubercles in the lungs, and in the 3rd animal there was an old calcified lesion in the lungs. In 1926, 7 years from the beginning of the experiment, there were still 2 of the infected animals which were reported in the 1919 experiment and which gave a positive reaction to tuberculin.

In the meantime, the second generation of these vaccinated animals were revaccinated and the vaccination repeated each following year. At the time of their report, the group of vaccinated animals consisted of 58 cattle living in contaminated surroundings. There is no record of how many of the vaccinated cattle became infected, as the tuberculin test was not done. These authors omitted the tuberculin test on Calmette's suggestion, as he believes that it is of doubtful diagnostic value, giving no information as far as exogenous infection is concerned. Furthermore, if in the vaccinated cattle an implantation of a virulent organism has taken place, setting up only a benign tuberculosis, tuberculin administered may bring about a violent allergic reaction, disseminating the virulent organisms. In such an event a progressive disease may follow. The validity of the claims for establishing protection in the vaccinated animals was based on autopsies done on a few cattle which have died from intercurrent disease.

Tzekhnovitzer³³ concluded that B.C.G. given orally in young guinea pigs does not prevent oral infection with virulent organisms. The animals may live a little longer than controls but the lesions are very similar to those seen in the control animals. Rabbits vaccinated subcutaneously lived longer than the controls and the lesions were not of the progressive type. In cattle after intravenous immunization with B.C.G. followed by 5 mg. of virulent bovine culture, the controls died in 6 weeks of miliary tuberculosis, while the sensitized animals survived and appeared apparently normal. Two, killed after 3 months, showed nodular tuberculosis. Two, killed 6 months after the virulent inoculation, showed subpleural tubercles, calcified bronchial and mesenteric lymph nodes and a few tubercles in the lung. Another animal killed in the 9th month showed a number of tubercles in the lungs. The last animal killed in the 10th month showed a caseous mass in the left lung. All were apparently in good health when killed.

Watson,³⁴ in a limited number of cattle vaccinated with B.C.G., observed no conclusive evidence of protection. The animals were vaccinated with B.C.G. in the usual way, were kept away from contaminated surroundings for a short period, and then put in with a tuberculous herd, exposing them to natural infection. The animals in the group were killed at various intervals from 2 to 24 months. All were free from tuberculosis.

A second series of animals were treated approximately the same as were the preceding series, kept under observation for 15 months and then killed. Progressive tuberculosis was found in every one of these vaccinated animals. The discrepancy in the two series is explained by the author in that the source of infection was different although the vaccinations were carried out exactly alike.

In a series of 4 unvaccinated new-born cattle which were put in contaminated surroundings and killed some 15 to 20 months later, only 1 of the animals had demonstrable tuberculosis. The author concludes that a large series must be employed and that animals with no natural resistance must be chosen for experiments of this nature. He calls attention to the possibility that the virulence of the organism which causes the infection in a herd may fluctuate from time to time. Tuberculosis may spread very slowly in one herd and very rapidly in another. This variation may be due to the natural resistance which some of the herds possess, the organism causing no clinical manifestation even with its continuous presence. Gradually the animals become resistant to this particular organism. However, as soon as a new organism is introduced into the herd, the occurrence of the disease is much more marked than previously.

Wilbert " reported a study of 15 chimpanzees and 59 Pitheciens in East Africa, which if it can be repeated will strengthen the status of the B.C.G. vaccination. Monkeys of all ages were vaccinated either by a single subcutaneous inoculation of 50 mg. or by five ingestions, each consisting of 15 mg. at intervals of 8 to 10 days, and all showed resistance when exposed to natural contact infection. Some of the monkeys have been under observation since 1924 and were still living and in good health at the time of writing. The life of controls and of infected animals has always been very short. Autopsies on many of the vaccinated chimpanzees which have died from intercurrent diseases showed no tubercular lesion. This author concludes that B.C.G. can establish a definite protection in monkeys.

PREPARATION OF VACCINE AND METHOD APPLIED IN INFANTS

The organism ordinarily is cultivated on glycerin potato bile medium. When a large quantity is desired, especially in the vaccine preparation, it is advisable to cultivate it on a synthetic medium known as "Sauton's." Surface inoculation is made by floating the seed and an abundant growth accumulates in a short time. Only cultures of 3 weeks' development are recommended by the author for the preparation of the vaccine. The fluid medium is removed from this 3 weeks' growth, and a number of sterile glass beads are introduced. The flask is fastened to a shaking machine and after 15 minutes of vigorous shaking it is diluted with a mixture containing 1 per cent dextrose and 4 per cent glycerol in water. The whole mass is well mixed and allowed to stand until the clumps settle. The supernatant suspension of living organisms is then diluted so that 1 c.c. represents 5 mg. moist weight of the bacilli. Two c.c. of this suspension are mixed with milk and fed to infants. The feedings are made on the 3rd, 5th and 7th days after birth. Each feeding represents approximately 400,000,000 of living organisms.

The history of the vaccination of infants with B.C.G. as a prophylactic measure dates from July, 1921, when Turpin and Weill-Hallé fed some infants at the Maternity Hospital in Paris. For the following 2 years the vaccination was practically neglected. It was not taken up seriously until July 1, 1924. In a recent article Calmette " and his coworkers tabulate the results from the 3 years' vaccination of 52,772 children, which cover a period from July, 1924, to December 1, 1927. Eight hundred and forty infants were vaccinated in 1924; 4,336 in 1925; 14,654 in 1926; and 32,942 in 1927. Sixty-two hundred and nineteen of the vaccinated were born in tuberculous families, 5,749 of whom have been under observation for 1 to 3½ years. Of these, 3,808

were vaccinated less than 1 year, 118 of whom died, making a general mortality of 3.1 per cent and a tuberculous mortality of 34 infants or 0.9 per cent. Tuberculous meningitis is given as the cause of death in 30 cases or 88.4 per cent of the tuberculous deaths. The remaining deaths were due to some other form of tuberculosis. Of the 84 infants in this group who died from other causes than tuberculosis, 29 or 34.5 per cent died from gastroenteritis.

The remaining 1,941 of these 5,749 infants represent a group from 1 year to 3½ years of age. Twenty-one deaths occurred in this group, or a general mortality of 1.2 per cent, 4 of whom, 0.2 per cent, died from tuberculosis.

In a third group of 917 children from 2 to 3½ years of age there was no tuberculous mortality. It is not quite clear if the third group is included in the second group.

Perhaps the best controlled study on infant vaccination is that made by Weill-Hallé and Turpin.⁴ Their statistics consist of 469 cases vaccinated with B.C.G., 92 of whom they lost track of and could not include in their study. Another group of 60 was excluded because the duration of time after the vaccination was too short. Of the whole group they analyzed only 317 cases which were well followed with the intracutaneous skin test. Death occurred in 14 of these 317 infants. Two hundred and thirty-six were from healthy surroundings and 67 from tuberculous environment. The 14 deaths were equally divided between the two groups, 7 in the first and 7 in the second. The skin test was done approximately every 3 months, and the results are tabulated in the following table:

Age in Months	INTRACUTANEOUS SKIN TEST	
	Infants Vaccinated, Living in Tuberculous Surroundings	Infants Vaccinated, Living in Healthy Surroundings
	Tuberculin Skin Test Positive in Per Cent	Tuberculin Skin Test Positive in Per Cent
3	11.1	
6	16.6	2.5
9	25.9	4.1
12	26.6	5.8
15	44.4	7.6
18	50.0	7.4
24	60.0	12.1
		28.0

A glance at this table shows that the tuberculin skin reaction was positive more frequently in the group of children who were in tuberculous surroundings than in the group in which apparently there was no source of infection. The tuberculin skin reaction does not give us any information, especially in the group vaccinated and living in healthy surroundings, as to whether the infection was due to B.C.G. or to an exogenous source. Sixty per cent of children at the age of 2

years living in contaminated surroundings have reacted positively to tuberculin. This probably means that a large percentage of infection in this group was of exogenous character. It does not vary in any way from the group of children who have never been vaccinated and have lived in tuberculous surroundings. It seems that in spite of the vaccination with B.C.G. and the sociological measures, the implantation with virulent tubercle bacilli has taken place.

Selter,⁴⁰ analyzing these figures, offers the same criticism. It would be interesting for this author to follow not only the children brought up in surroundings where the possibility of infection is great, but also in the second group which give no history of infection.

Sayé, Domingo and Miralbell,⁵⁰ using Calmette's method, vaccinated 203 children with B.C.G. Six deaths from tuberculosis occurred among the vaccinated, or approximately 3 per cent. A number of the infants died from gastroenteritis but unfortunately no record is given as to the nature of this gastroenteritis.

Moine⁵¹ in a study of 882 infants reports a mortality from tuberculosis in only 0.8 per cent. Biraud⁵² reports 2.46 per cent mortality from tuberculosis in a group of 1872 vaccinated infants. Ott⁵³ gives a mortality of 1.9 per cent from tuberculosis in 157 infants. Rougebief,⁵⁴ following 60 cases of 623 vaccinated infants in Algeria gives no mortality from tuberculosis. Blanc,⁵⁵ in Greece, reports no mortality from tuberculosis in 136 infants vaccinated. Cantacuzène⁵⁶ reports no tuberculosis mortality in 578 infants. Keller⁵⁷ also reports good results but he believes that living B.C.G. vaccination should be controlled with killed organisms. Bernard⁵⁸ had no accident in 20,000 children vaccinated in Indo-China. Malvoz and Van Beneden,⁵⁹ in Belgium, report only 1 death from tuberculosis in a group of 374 vaccinated infants, and Iakhnis,⁶⁰ of Lithuania, studying 472 vaccinated infants, reports that he obtained ten times more positive tuberculin reactions in the vaccinated children than in the unvaccinated. He has noticed no ill effects from the vaccination.

THE AUTHORS' STUDY ON THE BIOLOGICAL CHARACTERISTICS OF B.C.G. CULTURAL CHARACTERISTICS

Our study was based on cultures obtained from three different sources, one from Dr. Watson of Ottawa, Canada, another brought to us by Dr. Lawrason Brown from the Pasteur Institute, and the third was sent direct to us by Prof. Calmette.

The organism grows well on glycerinated bile potato medium. The single colonies are perfectly round and considerably moist. The growth appears from 15 days on, gradually increasing in size. In time the

glistening surface dries out, assuming a mat appearance. They are very easily emulsified and the suspension obtained is very similar to that obtained from the avian tubercle bacillus. The organism grows well on the surface of practically all fluid media used for the cultivation of the tubercle bacillus. Sauton's medium, recommended by Calmette, is very suitable for obtaining a large amount of growth. The filtrate after the 3rd week develops very strong tuberculin. Guinea pigs inoculated with the organisms develop skin hypersensitiveness in about 15 days.

The first culture studied was that obtained from Dr. Watson. Eight guinea pigs were inoculated subcutaneously, the amount varying from 2 to 16 mg. Two guinea pigs received 2 mg.; 2, 4mg.; 2, 8 mg.; and 2, 16 mg. Sixty-one days after the inoculation 1 animal from each group was killed and tuberculosis of the viscera was present. The other 4 animals were allowed to live. Five months from the beginning of the experiment, 1 of the animals which was inoculated with 4 mg. died and the cause of death was recorded as generalized tuberculosis. In the 6th month the animal receiving 16 mg. also died from generalized tuberculosis. At the 7th month the 2 remaining animals, i.e., 1 receiving 2 mg. and 1, 8 mg., were killed. At autopsy no evidence of tuberculosis could be found. At that time we could not explain the discrepancy observed in these animals, 2 having died from tuberculosis, while the other 2 living 7 months were free from tuberculosis. The experiment was suspended for a short time until we obtained another culture.

With the second culture an attempt was made to increase the virulence by rapid animal passage. The technic consisted in inoculating from 1 to 2½ mg. into the right testicle of 2 guinea pigs. After 7 to 14 days the infected testicles were removed aseptically under anaesthesia. The tissues were triturated and reinoculated into the right testicle of 2 other animals. Four such series were done. Three gave negative results after the 3rd, 4th and 5th passages. There was only localized tuberculosis which eventually healed. In one series, however, on killing the animal of the second passage, there was generalized tuberculosis of the viscera, and the spleen was large and nodular. The lymph nodes were very caseous. This caseous material was inoculated in the other guinea pigs and invariably generalized tuberculosis developed and death occurred.

During the cultivation of B.C.G. on fluid media a difference in the character of the growths appeared in some of the flasks. Some were veil-like with small islands of dense growth scattered throughout, while in others the growth was heavy and of uniform structure. This imme-

diately suggested to us the possibility of variants similar to those observed in the reproduction of other acid-fast organisms, and if B.C.G. could be dissociated, at least we could explain some of the discrepancies observed in animal inoculations.

A small amount of the third culture received directly from Calmette was triturated in salt solution with a pH of 7.8, filtered through two layers of Whatman paper No. 5 and 5 drops of the filtrate smeared over the surface of gentian-violet plates. After 6 weeks there appeared two distinct types of colonies. One, which predominated, was waxy, with smooth wrinkles, the folds of which extended from the center to the periphery. The outline was clear-cut, round, raised, and did not extend into the medium. This colony was very difficult to emulsify in salt solution of pH 7.2. We shall call this the "R" colony. The other colony, which we shall refer to as "S," was small, in irregular wrinkles on the surface and was not as smooth and waxy as the "R" colony. The outline was irregular and at times extended into the medium. This colony was much more readily emulsified.

On synthetic fluid media the "R" colony grows in the form of small islands or peninsulas and the growth is readily broken up and lifted with the loop. On the same media the "S" colony grows more tenaciously and in a solid mass very much like a thin veil. In attempting to remove a small amount of the surface growth, practically the whole surface is lifted. Both of these colonies produce tuberculin. Inoculated into guinea pigs, both set up a hypersensitive state to tuberculin. The complement fixing and precipitin antibodies can be demonstrated in rabbits following intravenous inoculations.

A comprehensive study of the biology of the "R" and "S" colonies, with special reference to virulence and immunity, will appear in the near future. All the work so far points out that the two colonies dissociated from the original Calmette strain behave differently, not only in regard to cultural characteristics, but also in virulence for guinea pigs and rabbits. The "R" colony always produces some tubercles which in time heal, while the "S" colony invariably produces progressive disease terminating in the death of the guinea pig. The chemistry of the two colonies is also different.

IMMUNITY EXPERIMENT

The value of B.C.G. vaccination was tried in a limited number of animals and the experiment is not yet completed. The experiment consisted of 38 vaccinated and 26 control guinea pigs. They were divided into four groups.

Group I consisted of 8 very young guinea pigs not older than 36

hours. They were fed with an emulsion of B.C.G. bacillus, four doses of 0.8 mg. being given, a total amount of 3.2 mg. dry weight or approximately 20 mg. moist weight as used by the French investigators. Four and one-half months later 3 drops of a suspension of living virulent culture consisting of 100,000,000 organisms per c.c. were instilled in the eye. Seven controls were infected by the same method. Eight months after the instillation with living tubercle bacilli, in the vaccinated animals, 3 are still living and 5 have died between the 130th and 231st days. Three unquestionably died of tuberculosis. One died from pneumonia complicated with tuberculosis, and in the other which died from a chronic otitis the cervical lymph nodes were enlarged and contained acid-fast organisms. Of the control animals 5 are living and 2 have died. Death in 1 of the animals was due to tuberculosis and in the other to chronic otitis with some tuberculous involvement.

The second group consisted of 8 sensitized animals and 9 controls. In this group also very young guinea pigs not older than 36 hours were used. They were inoculated subcutaneously with a suspension of B.C.G. of 0.25 mg. every 5th day. Four doses were given, a total amount of 1 mg. dry weight or 8 mg. moist weight. The vaccinated and the control animals were then infected by the inhalation method with H 37. At the end of the 8th month, 1 of the vaccinated animals is living and 7 are dead. Four died of extensive tuberculosis, 1 of cellulitis with some tubercular lesions and in 1 the cause of death was undetermined but there were tubercle bacilli at the site of inoculation. The 7th animal died of postpartum peritonitis with considerable amount of tuberculous involvement. Six control animals died of generalized tuberculosis.

The third group consisted of 10 full grown guinea pigs. Four inoculations were made subcutaneously from 2 to 3 days apart. A total amount of 12 mg. of moist weight of the organisms was given. The infecting dose was given subcutaneously a month later, consisting of 500 organisms of H 37. One year later 3 of the animals are still living and 7 are dead. Five which lived more than 279 days died of generalized tuberculosis. One living 98 days died with chronic sinusitis with no macroscopic evidence of tuberculosis. In another animal which also died with sinusitis on the 102nd day there was tuberculosis in the spleen and lymph nodes.

The fourth group consisted of 12 adult guinea pigs. Vaccinations were made intraperitoneally and four doses were given between 2 and 3 days interval, or a total amount of 12 mg. moist weight. A month later they were inoculated subcutaneously with 500 virulent H 37 organisms. One year later 4 of these 12 animals are still living and 8

have died from various causes. Two died shortly after the inoculation and have been excluded from this group as death occurred too soon after infection. One died on the 79th day from gastroenteritis with no evidence of tuberculosis. Another died on the 95th day with chronic otitis and no tuberculosis. Three others died on the 123rd, 238th and 279th days of generalized tuberculosis. In 1 animal dying on the 264th day the cause of death was due to strangulated gut and tuberculosis was present in the spleen and lymph nodes.

Ten controls were used for Groups III and IV. They were inoculated also with 500 tubercle bacilli of the same origin. A year later 1 is living and 9 are dead. One died on the 97th day with chronic otitis with demonstrable tuberculosis in the spleen, one on the 100th day of peritonitis and no tuberculosis, and 1 on the 251st day of pneumonia with tuberculosis of the spleen. The remaining 6 guinea pigs died of generalized tuberculosis, some living as long as 351 days.

DISCUSSION

In the preceding pages an attempt has been made to bring together some of the outstanding features concerning the method of B.C.G. vaccination. The organism in question was isolated some fifteen years ago or more from a heifer. At the time of isolation it was pathogenic for cattle, rabbits and guinea pigs. By cultivating it in glycerinated ox bile potato during this period, it has almost completely lost its virulence, but has maintained the property of forming localized tubercles, of producing tuberculin, of rendering inoculated animals skin hypersensitive, of producing the formation of specific antibodies and according to the sponsors of producing an immunity against virulent reinfection.

According to the majority of workers, B.C.G. is innocuous for small laboratory animals, lesions once established having a tendency to heal. The experiments of Gerlach,³³ Nobel,³⁴ Kraus,³⁵ Selter,³⁷ and others are not, however, in agreement as to the innocuousness of the organism. Some of them have been able to establish progressive disease in guinea pigs, eventually leading to death, and Nobel and Gerlach were able to pass the lesions from animal to animal. Korschun⁴¹ has been able to increase the virulence of B.C.G. in animals by treating them first with diphtheria toxin.

In two instances we have been able to demonstrate generalized tuberculosis by direct inoculation and in one other instance tuberculosis was established after the second animal passage. In defending their position Calmette and his collaborators state that any positive tuberculosis in animals when inoculated with B.C.G. is due to a con-

tamination with a virulent tubercle bacillus. Accusing any trained worker of carelessness in contaminating cultures is not a justifiable criticism.

An explanation of these discrepancies reported on the virulence of this organism is offered by the recent work on dissociation which has been observed in the majority of bacterial species.

Recently we²² have observed that any culture of tubercle bacillus may contain two types of colonies which can be differentiated by their cultural characteristics and virulence for animals. We have found two types of colonies present in a culture of B.C.G., one "R" colony (rough) * which is non virulent, and the other "S" (smooth) * which is virulent for guinea pigs. The "R" colony grows very well on glycerin bile potato and Sauton's media, while the "S" does not produce any visible growth in bile but grows in Sauton's.† The latter, however, does not die in the bile medium. Scrapings made from the surface of the inoculated culture 1 and 2 months after incubation invariably produce progressive tuberculosis in guinea pigs, involving the lymph nodes and the viscera. The lesions are similar to those seen in guinea pigs inoculated with bovine tubercle bacilli. These scrapings will also yield a profuse growth after cultivation on suitable egg media. From the lesions of this "S" colony we believe that B.C.G. has still the ear mark of a bovine organism but lacks the power of producing progressive tuberculous lesions in rabbits. By continuous subculturing on potato bile media, Calmette has gradually eliminated most of the "S" colony, allowing the "R" to predominate. The virulent "S" colony, however, has never been completely eliminated, and although present in very small numbers, under favorable conditions it may increase in number to such an extent that reversibility of virulence may take place. An observation of this nature is not uncommon with any other bacteria. It cannot be thought that the tubercle bacillus is an exception.

The animal experiments submitted as the basis of vaccination with B.C.G. are unsatisfactory. There is, at most, only weak evidence to show that this organism establishes any appreciable degree of protection in small laboratory animals. The only evidence being that some of the vaccinated animals outlived the controls. Selter²³ believes that some degree of protection can be established, but this is due to the slight degree of virulence still present in the organism. We are inclined to believe that the protection conferred by B.C.G. is very slight and not greater than that obtained with heat-killed organisms where there

* The nomenclature is arbitrary. They are both rough but have a different structure.

† In a recent paper we have been misquoted by Calmette.²³

can be no question of danger. The life cycle of the tubercle bacillus is not completely understood and especially of the B.C.G. We consider its use, at least for the present, should be deferred. After the accumulation of more experimental data we may be brought to modify our position.

We cannot completely ignore the autopsy findings of Tail lens,⁶³ Girod and Debarge⁶⁴ in infants who had been vaccinated, nor the tuberculin reaction observed by Weill-Hallé,⁶⁵ where there was evidence that B.C.G. produces some tuberculous changes in vaccinated infants living in healthy surroundings. The mere fact that 28 per cent of infants vaccinated and living in healthy surroundings reacted to the intracutaneous tuberculin skin test forces us to such a conclusion. It will be interesting to know if any of these infants develop clinical tuberculosis later in life. Of course if such occurrence takes place, there are no means for determining whether the disease is due to B.C.G. or to some exogenous infection.

Further, in regard to the immunity in cattle, the results reported by Guérin, etc., have not been universally accepted by men who have studied this problem in cattle. Watson,⁶⁶ of Ottawa, states that tuberculosis may spread very slowly in one herd and again very rapidly in others and he believes the resistance existing in the former is due to the persistence of the tubercle bacillus in the animal body for many years, causing no clinical disease under normal conditions. If, however, some of the infected but not ill animals were put in with a stock free from tuberculosis, they may infect fatally many cattle of the second herd, the original infected lot outliving the second lot. This author also believes that very little could be gained by vaccinating calves, and even if the vaccinated animals were more resistant to superinfection than the unvaccinated, the former could not completely resist an implantation of a virulent organism. After such implantation takes place, the organism in all probability will be localized in the lymph nodes and remain there for a long time doing no damage, but after years of strenuous milk production the animal's resistance may diminish to a point where disease begins to develop.

Calmette's original cattle experiments in 1913⁶⁷ are also open to criticism. He only uses 1 control in each group with 7 or 8 vaccinated animals. The statement is made that 3 mg. of the Vallée bovine strain invariably killed the control in 5 weeks of generalized tuberculosis, while the vaccinated continued in good health. Watson, however, using the same Vallée strain observed that some control calves which had been inoculated intravenously with 250 mg. of the organism and killed 11 months later showed only lymphatic tuberculosis. Did Calmette

use identical suspensions in his control in each experiment; or did he assume from previous experiments that the Vallée strain always killed in this dose? We now know that unless we cultivate our human H 37 and bovine B 1 tubercle bacilli on suitable media the virulence diminishes. For this reason when testing the resistance of vaccinated animals the same number of controls must always be used.

Uhlenhuth⁴⁰ is inclined to believe that the cattle experiments reported by Calmette where infection was by contact were not carried out as they should have been. The heads of the animals were turned toward the wall, thus preventing the droplet infection. At least the certainty of natural infection was lessened.

We suggest that the success reported by Guérin in cattle experiments was not due to the protection established by vaccination with B.C.G., but to the elimination of the contaminators on the one hand, and to the development of natural resistance on the other. This point seems obvious in the animals killed 7 years after they have reacted positively to tuberculin, the autopsies revealing only few small lesions.

The favorable reports coming from Europe on the vaccination of new-born babies are so amplified that they have reached the point of distortion. Careful analysis of the statistics submitted reveal one outstanding fault, viz., that not a single group of vaccinations has been controlled. We have failed so far to find comparable figures which may lead us to some conclusion. Mortality rates from tuberculosis in infants, in one instance, are quoted as far back as 1889. Have not the conditions and our knowledge of sociological measures been improved in recent years so as to bring the mortality to a lower level? Calmette claims that in France he has reduced the mortality from tuberculosis in the first year of life from 25 per cent before the vaccination to 0.9 per cent after the vaccination. Does this 25 per cent mortality in infants in tuberculous families refer to the group of known infected as detected by the positive tuberculin reaction, or does it represent a percentage from the general mortality? It is not quite clear in our minds.

It must be remembered that most of the vaccinated children born of tuberculous mothers were removed from contact for at least 4 months, thus decreasing the possibility of an infection in this early period of life. This isolation gives the infants an opportunity to adjust the normal mechanism of defense against any infection. No infants in France without vaccination have been submitted to a similar preventive measure early in life. How then can we compare the two groups, the vaccinated and the unvaccinated? Two factors are involved in these studies, vaccination and hygienic preventive measure.

Further, how can we determine the cause of death in infants from tuberculosis without post-mortem examination? There are other forms of tuberculosis in infants besides tuberculous meningitis which are not easily diagnosed. Calmette presents only 3 autopsies, involving a study of several hundred deaths. Many of the vaccinated infants have died of gastroenteritis; in fact, over 30 per cent of the deaths occurring in the vaccinated infants not due to tuberculosis have been recorded as gastroenteritis. Could it not be possible that in some this gastroenteritis was of a tuberculous nature? While it is probable that the organism, by feeding, may find its way into the mesenteric lymph nodes and then be distributed throughout the body, it is conceivable that when such large doses are administered at birth the mucosa may become involved directly. The innocuousness of the organism has been based on the observation that no fatalities have been reported after oral vaccination. Fortunately, contrary to Calmette, the experimental evidence is against any great danger of infection taking place by this route. Findel,⁶⁶ Reichenbach,⁶⁷ Selter,⁶⁸ Brown, Petroff and Pesquera⁶⁹ could not readily infect guinea pigs by feeding. The only misgiving we have is that some virulent type (S) may be carried along with the non-virulent.

Weill-Hallé observed only 2 per cent positive tuberculin reactions up to 3 months in a group of infants vaccinated by the oral route and living in healthy surroundings. When the vaccine was administered subcutaneously 100 per cent of the infants reacted intracutaneously to tuberculin. Is this not sufficient proof that very few of the organisms pass through the intestines of the infants?

In explaining the 0.9 per cent mortality from tuberculosis in infants vaccinated with B.C.G., Calmette⁷⁰ and Surrez⁷¹ do not, as a rule, attribute it to an infection of exogenous character subsequent to vaccination. They profess to believe that tuberculosis occurred in these infants usually as a result of fetal infection with the ultra-microscopic filtrable form of the tubercle bacillus which traversed the placenta, a theory which is still a speculation. In our laboratory we have not yet confirmed the existence of a Berkefeld filtrable form of the tubercle bacillus.

We are further told not to worry about the B.C.G. because it is a bovine organism which is not virulent for human beings; but is it not a false security to depend upon its presence for protection without any knowledge of what immunity, if any, it confers? Infection with the bovine tubercle bacillus in infancy is today a rare occurrence; but what becomes of this organism after puberty in those that have been infected? Does the bovine organism transmute into the human

tubercle bacillus after inhabiting the body for a long time? All evidence up to the present is against such transmutation, but we must not be too dogmatic in completely ignoring its possibility.

The differentiation of the human and bovine cultures has been based on the ability of the organism to produce progressive disease in a rabbit. If a culture inoculated in dosage of 0.01 mg. infected the rabbit and death followed in 60 days, then the organism was bovine, and if it did not, it was human. This holds true probably with the two extreme types; but how about the intermediate ones? If B.C.G. was a bovine tubercle bacillus at the time of isolation, it must possess all conventional biological characteristics, i.e., it must be virulent for rabbits, cattle and guinea pigs and give the alkaline curve on broth as described by Theobald Smith. The dissociated "S" virulent colony of this organism infects only guinea pigs at present with a marked lymphatic involvement comparable to many other bovine tubercle bacilli, is no longer pathogenic in small dosage for rabbits, and the acid base curve is that seen in the human organism. In other words, the organism has some human and some bovine characteristics. Mudd¹¹ also points out that B.C.G. behaves like the human strains studied in his interfacial experiments.

The main object of the present campaign in prophylactic immunization has been to reduce the mortality from tuberculosis during the first year of life. Vaccination with living organisms has been suggested and very extensively used. There is evidence that the general mortality has been reduced and there are indications that some of the infants have been infected, while others, regardless of the prophylactic measures and vaccination, have been reinfected with small numbers of virulent organisms.

It seems advisable and a much safer procedure not to introduce another living organism into the body but rather, by hygienic measures, to eliminate as much as possible the danger of excessive infection from the new-born babies. Such preventive measures are effective, as was pointed out by Grancher some twenty-five years ago, and more recently, Debré and Lelong¹² and others have been able to prevent infection in infants by removing them from their tuberculous mothers. König,¹³ studying the mortality in Prussia, states that in 1925 the general mortality among 246,488 infants under sanitary supervision was reduced from 12 to 5.5 per cent. Among them there were 188 male infants living in tuberculous surroundings of whom only 6.3 per cent reacted positively to tuberculin and 140 females of whom only 5.7 per cent reacted. These remarkable figures have been obtained not by B.C.G. vaccination but by educational and preventive measures.

In the United States and Canada where the campaign against tuberculosis is made very effective by the use of various sociological and health measures, mortality and infection in childhood have decreased to a very low level and we cannot see why such a prophylactic measure as advocated by the French investigators should be introduced at present. We may recall that Friedmann's vaccine which was condemned in 1912 was also a living organism, and the potential virulence of it was probably of lower degree than B.C.G. We believe that watchful waiting is the best position at present in reference to vaccination of infants. We cannot completely ignore the possibility of a prophylactic vaccination method and the one advocated demands our careful consideration. The careless use of poor statistics obtained from a study of human beings is going to lead us nowhere.* Therefore, we strongly advocate experiments in cattle on a large scale in order to confirm or refute Calmette's claims.

Institute for the Protection of Child Health in Soviet Russia

BY government decree there was recently established in Moscow the Government Scientific Institute for the Care of Child Health. The institute, which is doing theoretical as well as practical work, has the following purposes:

- 1 Study of the physical and psychological nature of normal and abnormal children between the ages of 4 and 17 years
- 2 Study of methods for the prevention and treatment of physical and mental disorders in children of these ages
- 3 Training of workers for the care of the health of children and young people

The institute consists of the following four divisions: division of the normal child, division of the physically abnormal child, division of mental and nervous disorders, and the statistical division. A separate section will be devoted to the training of physicians as specialists in child health work.

The following auxiliary agencies are connected with the institute: an experimental dietetic dining room; a clinic for normal children, one for physically defective and one for mentally defective children; a sanatorium, a playground conducted on the principles of physical therapy; a diagnostic clinic, and a museum. The institute is cooperating with other organizations interested in child health.—*Voprosi Zdravoo Khranenia*, Moscow, 1 74, 1928, 4: 81. 1928.

Refugees gathered at Santa Paula immediately after the flood, lined up for typhoid immunization

Sanitation in the St. Francis Dam Disaster*

WALTER M. DICKIE, M. D., FELLOW A. P. H. A.

Director, State Department of Public Health, Sacramento, Calif.

THE St. Francis dam in San Francisquito Canyon of Los Angeles County, impounding more than 12 billion gallons of water, broke about midnight of March 13, 1928. This dam, of concrete construction, had a maximum height of 205 feet, was 700 feet long, and was 175 feet thick at the base. It failed completely, with the exception of a small section near its middle, and the force of the flood water was so great that it broke the structure into great blocks of concrete up to about 10,000 tons in weight, distributing them for a distance of several thousand feet down stream. The flood waters attained a maximum depth of about 125 feet, and traveled, in a solid wall, down San Francisquito Canyon at the rate of 18 miles an hour. The flood followed this steep and narrow gorge for its length of 9 miles from the dam and then down the Santa Clara River $43\frac{1}{2}$ miles to the ocean. It required about 5 hours for the enormous rush of water to travel the 52 miles from the dam to the Pacific Ocean. The Santa Clara River, like so many western streams, is practically an arroyo, containing water only intermittently during the rainy winter seasons. Practically the entire flow of this river is storm water and it is only during periods of heavy rains that it carries any stream whatsoever. It has a well defined channel, however, and the direction of the flood was determined to a certain degree by the topography of the dry bed. This immense volume of water, travelling at a terrific rate of speed, was hurtled from one

This huge block of concrete, 205 feet in height, the central section of the dam, was all that remained standing.

side of the Santa Clara River bed to the other, spreading out where the stream bed was flattened, piling up at its narrow confines, becoming dammed momentarily at bridges where debris had caught, and eventually carrying out all bridges, with the exception of one located not far from the Pacific Ocean.

The dry character of the stream bed and the comparatively short distance traveled by the flood, and its high rate of speed rendered the problems of sanitation far less acute than would have been the case with a flowing stream and a slow rising flood. The fact that there were no levees to break and that comparatively few towns or ranches were located immediately adjacent to the stream bed, made relief work and sanitation associated with the disaster far less arduous than in flood disasters in other parts of the country.

The town of Santa Paula, with a population of 7500, was the largest town involved. Santa Paula and Saticoy were the only towns in the flood which had municipal water supplies and sewage disposal plants. Most of the damage to property was done in Santa Paula and its vicinity. About 300 bodies were recovered, most of which were buried in debris. There are at least 200 missing, all of which are probably covered with many feet of silt. The bodies of individuals who were caught in the flood immediately below the dam were carried like corks on the crest of the flood, and many were recovered on the lower reaches of the Santa Clara River and even on the beach at the Pacific Ocean. Bodies of individuals who were caught in the flood waters farther down stream lodged in tangled masses of brush, trees and other debris caught in groves of willow trees at the banks of the stream.

As soon as word of the disaster was received, representatives of the California State Department of Public Health left Los Angeles and San Francisco simultaneously. The first order issued by these officials upon their arrival in the flood area was that all milk supplies in the entire valley must be pasteurized. Immediately thereafter a regularly organized program was instituted and enforced through the coöperation of the local health officers, physicians, nurses, Red Cross workers, city and county officials, representatives of the Bureau of Light and Power of the City of Los Angeles, and a citizens committee of Santa Paula. The staff of the State Department of Public Health within the flooded area consisted of 2 epidemiologists, 1 district health officer, 1 physician specialist in child hygiene, 3 sanitary engineers, 4 sanitary inspectors and 2 public health nurses. The four main activities carried on by this staff were:

1. Safeguarding water supplies and sewage disposal plants
2. Safeguarding milk supplies
3. Offering immunization against typhoid fever to all individuals within the flooded area
4. Sanitary inspection of towns, ranches and the silt covered river bed

The Safeguarding of Water Supplies and Sewage Disposal Plants—The municipal sewage disposal systems at Santa Paula and Saticoy were washed over and it became necessary to provide emergency chlorination of the Santa Paula municipal septic tank effluent because of the impairment to the efficiency of the plant. Flood water entered the municipal water reservoir at Saticoy, making necessary the immediate disinfection of the water contained therein. Private and irrigation wells along the fringe of the flood, about 100 in number, located both above and below the Santa Paula sewer farm, were inspected and examined bacteriologically for contamination. Field equipment from the Los

Another view of the central section of the dam

Automobiles and wreckage partly buried in silt

Angeles city water department laboratory made possible the making of analyses in the field, speeding up this work immeasurably.

Safeguarding of Milk Supplies—Following the order, which provided for the immediate pasteurization of all milk supplies, the inspection and safeguarding of all such supplies were placed under the direction of the County Sanitation and Milk Inspector. No milk, other than pasteurized milk, was permitted to be used in any of the refugee camps which were in charge of local committees. Following the establishment of the safety of all water and milk supplies at dairies and the establishment of sanitation conditions, the distribution of milk under normal conditions was resumed.

Immunization against Typhoid Fever—Immunization against typhoid fever was offered to the inhabitants of the entire Santa Clara Valley. The representatives of the State Department of Public Health, in coöperation with local health officers, physicians and nurses, established clinics in the various communities: Santa Paula, Fillmore, Piru, Bardsdale and Saticoy, as well as other more isolated communities. A total of 3106 individuals in the flooded district were immunized against typhoid fever. Of these, 1080 were immunized by representatives of the State Department of Public Health, and 2026 were immunized by local health workers at Santa Paula. The state provided the vaccine for all immunizations. On March 23, first injections at immunization clinics were discontinued.

Sanitary Inspections—The work of the state sanitary inspectors, consisted of the cleaning of dairies, the inspection of homes rehabilitated following the recession of flood waters, the inspection of quarters

Temporary fly-tight toilets installed in the refugee camp at Santa Paula

provided for refugees and all labor camps, the proper disposal of carcasses of dead animals, the disinfection of open cesspools and vault toilets, the burning of debris, the inspection of vegetable truck gardens and similar activities.

RELIEF MEASURES

General relief measures were carried on under the direction of the Red Cross, the American Legion and other local organizations. Within a few hours after the recession of the flood waters provisions were made for housing homeless Mexicans in Santa Paula, of which there were between 300 and 400. Clothing was provided and breakfast was served to 168 families at 7 o'clock on the morning of the day of the flood. Hospitalization was provided for the relatively small number who needed such care. A tent city was established for the habitation of those rendered homeless on account of the flood. This community was constructed along sanitary lines and provided adequate temporary accommodations for the homeless. About 400 houses in Santa Paula, located in an area which comprised from 10 to 15 city blocks, were destroyed or so badly damaged that rebuilding was necessary.

As soon as the emergency conditions abated, the City of Los Angeles, which assumed full responsibility for the disaster, dispatched between 2,000 and 3,000 men to clean up, in military fashion, the entire Santa Clara River bed. Tractors and trucks were used to remove debris, in which were found automobiles, human bodies, dead horses and other animals. Most of the debris was moved to safe distances and burned. Arrangements were made by which all crews

working in the river bed were provided with portable toilets. Isolation tents were provided at all labor and refugee camps in order to provide temporary hospitalization facilities for those who became sick or were injured.

In order to coöperate more closely with the health officials, the Los Angeles Bureau of Light and Power appointed local physicians to care for the sick, and the contracting company which carried on this work appointed a sanitary inspector to visit and supervise sanitary conditions in all camps within the flooded area. The district affected by the flood lay entirely within Ventura County, excepting the upper part of the district, the sanitation of which was cared for in an able manner by the Los Angeles County Health Department.

The emergency in the St. Francis dam disaster and the flooding of the Santa Clara river bed constituted an acute emergency. The disaster was characterized by the comparatively high mortality and the short duration of disaster conditions. The work of sanitation was, as a result, completed quickly and a return to normal conditions was effected within a short time. Had the population in the Santa Clara River watershed been larger the loss of life would have been enormous, as there was little time for warning and small chance for escape. No cases of communicable diseases occurred as a result of flooded conditions. The excellent coöperation of local authorities and the City of Los Angeles, as well as that provided by citizens' committees, the American Red Cross, the American Legion, and others, aided materially in the prevention of the occurrence of communicable diseases and brought about the speedy return to normal conditions.

Stream bed of the Santa Clara River after the flood waters had passed. Many bodies of the dead were recovered in the debris which piled up against the willow trees shown in the background.

The Preventorium School

A Factor in the Community Tuberculosis Program

W. P. SHEPARD, M.D., FELLOW A.P.H.A.

and

MARGUERITE L. SPIERS

Berkeley, Calif.

THE Berkeley Sunshine School is an adaptation to the public school system of the preventorium régime. Its plan was inspired by a study of the following:

1. The inadequacies of the so-called open air school
2. The satisfactoriness of the Lymanhurst School of Minneapolis¹
3. The need for preventorium régime of a larger number of children than were being reached
4. The necessity of modifying the school curriculum for the benefit of certain children with organic defects
5. The large number of school days lost by children who were convalescent from acute illness

This school has now been in successful operation in Berkeley for a year and a half. Results being obtained are therefore of interest.

Berkeley, with a school population of 15,000, was found to have continuously in the elementary schools between 100 and 150 children who were in need of preventorium régime, and another 25 to 50 who were in need of curriculum modification because of organic defect or prolonged convalescence from acute illness. Berkeley's quota of beds at the county preventorium was but 8, less than 5 per cent of the number needing this care. Admission to the preventorium was further restricted by limiting such admissions to persons unable to pay a private physician. The preventorium turnover of cases was very slow. Some children became sanatorium candidates before their turn came for preventorium admission. A study of 40 children discharged from the preventorium or sanatorium for 6 months or more showed the following conditions:

Readmitted to sanatorium or preventorium	9
On waiting list for readmission	10
Failing to improve	17
Showing steady improvement	4
Total	40

Further study of the 36 who failed to show steady improvement disclosed the fact that all were being subjected to greater physical strain than they could stand, and they were not receiving sufficient rest.

The Sunshine School was organized to care for children in the following groups:

Convalescents from acute illness

Children with or without known tuberculous infection in danger of developing tuberculous disease

Cardiacs needing increased rest, limited activity, and careful supervision of exercise

Children with other organic defects who would be benefitted by a rest régime

Children discharged from the preventorium or sanatorium who were still in need of increased rest and close medical supervision

For purposes of economy the school was housed in an elementary school building and made an administrative unit of that school. The capacity was limited to 40 children for the first year, and then expanded to 60 children. Space required is two dormitories, (converted classrooms), school cafeteria, (used by entire school), three classrooms, shower and dressing rooms, and a sun platform erected on the school grounds. The project was financed by the Berkeley Board of Education, the Berkeley Health Center, the Alameda County Tuberculosis Association, California Tuberculosis Association, Berkeley Exchange Club, and the Berkeley School Lunch Committee.

The total budget of the Sunshine School for the first year, covering cost of 40 children, is shown in Table I. This budget does not include any part of the overhead of the elementary school in which the Sunshine School is housed.

The maintenance cost per pupil-day at the Sunshine School, based upon figures for the year 1926-27, was 80 cents. This is 17 cents per day in excess of the cost per pupil-day in the regular elementary school in which it was housed. The saving over the per diem cost at any preventorium is apparent.

TABLE I
FIRST YEAR BUDGET OF SUNSHINE SCHOOL

Item	Source of Income		Total Amount
	Board of Education	Coöperating Agencies	
Original Equipment	\$1,682.00	\$1,496.95	\$3,178.95
Maintenance	3,706.50	2,332.84	6,039.34
Total	\$5,388.50	\$3,829.79	\$9,218.29

Staff of Health Workers—In addition to the usual school staff, the following persons carry out the health program under supervision of the Director of Health Education for the Berkeley Schools, who also holds the position of City Health Officer, and Medical Director of the Berkeley Health Center:

School Physician—The school physician is in charge of admissions, medical supervision and follow-up. He is also chief of pediatrics and

conducts the Sunshine School admission clinic at the health center.

Adviser in Tuberculosis—This worker also holds the position of superintendent of social service for the health center. She represents the medical director in health administration of the school.

Teachers—There are 3 teachers, who in addition to their teaching, supervise rest periods, and the lunch hour.

School Nurse—The school nurse is on duty at the school half time. She takes charge of sun and air treatments, and general health supervision under direction of the school physician. She also correlates the Sunshine School with the public health nursing staff of the city.

School Dietitian—She is in charge of the school cafeteria, and plans the menus.

Requirements for admission specify that applicants must be Berkeley residents, from the first 6 grades. Their financial status does not determine eligibility, this being determined by physical need.

They must be examined in the health center pediatrics department, where each case is worked up medically. Each child must be rendered free from any condition which will prevent improvement in the Sunshine School, and treatment is arranged through the family physician or in health center clinics.

In addition to medical findings, the health center social service department reports on home conditions, and determines the ability and willingness of the family to carry out the school program in the home.

Sun Treatment

Case work is done if there are social conditions which interfere with the patient's physical improvement.

The amount of school work is limited to 3 hours daily—time enough to cover only the essentials. This amount of time has enabled practically all children to keep up with their school grade.

School hours are from 8:45 a. m. to 4:00 p. m., and lunches must be eaten in the cafeteria under supervision. The following schedule is used:

8:45	Temperatures taken and inspection made by nurse for communicable diseases
9:00-10:00	School
10:00-11:00	Sun or air exposure
11:00-12:00	Rest hour
12:00	Temperatures taken
12:45- 1:00	Lunch
1:00- 2:00	Rest hour
2:00- 4:00	School

A mid-afternoon lunch of crackers and milk is served before the children go home.

Children are weighed once a week, and a complete record of weights, temperatures, sun exposure, and other medical data, is kept by the nurse, and is gone over each week by the school physician.

Further details of the medical régime have been described by Potter.³

RESULTS OBSERVED

Table II shows medical needs were met in 62 out of 79 children, or 73 per cent. This table also shows complete success to date with the group of ex-sanatorium and ex-preventorium children. For the entire group of convalescent, malnourished and tuberculosis observation cases, totalling 48, the Sunshine School régime was successful with 33, or approximately 70 per cent. In these percentages the number of

TABLE II
MEDICAL OUTCOME AFTER 3 SEMESTERS

Medical Problems	Improved sufficiently to be transferred to regular school	Improved but remaining in Sunshine School	Unimproved but remaining in Sunshine School	Medical Outcome Unimproved and transferred to an institution	Discharged for poor coopération	Total
Convalescent or malnourished	5	6	0	2	1	14
Tuberculosis observation cases	11	11	2	6	4	34
Cardiacs	0	3	0	1	1	5
Asthmatics	1	4	0	0	0	5
Ex-sanatorium or ex-preventorium children	12	9	0	0	0	21
Total	29	33	2	9	6	79

*Rest Hour*

children discharged for poor coöperation are considered treatment failures for the reason that coöperation might have been obtainable if the children had been removed from the home to a preventorium.

There is a marked reduction in the number on the preventorium waiting list. This has been reduced from 60 to less than 10.

An increased turnover is shown at the preventorium. Many children are discharged from the preventorium to the Sunshine School with satisfactory results.

There is a continued gain in children discharged from the preventorium, whereas, previously, many of these children showed retrogression.

A more effective means of health education of parents is available than would be possible if the child were removed from the home.

A greatly increased interest is shown in child hygiene and school health work by the community at large. This type of health activity very easily sells itself to the community because of its tangibility. In spite of early difficulties in financing this institution, it is now safe to say that a number of agencies would volunteer support for its continuance if necessary.

CONCLUSIONS

1. A school of this kind carefully operated along sound health, social and educational lines is a necessary adjunct to the tuberculosis program of a community.
2. Such a school is one solution for the economic difficulty of providing adequate preventorium space in the average community.
3. This type of school is superior to the so-called open air school because:
 - a. Health work is more intensive.
 - b. Rest receives more emphasis.
 - c. Sun and air exposure are made part of the program.
 - d. It calls for a complete break from the child's past routine which tends to impress both child and parents and thereby obtain better coöperation.
4. Such schools will not replace the preventorium, but are best regarded as an

auxiliary to the preventorium and sanatorium, as well as to the school health program. If future experience bears out our observation that 73 per cent of these children can be cared for without subjecting the community to the expense of putting them in a preventorium, then it is felt that such a plan is justified. On the other hand, some provision must still be made for the 27 per cent who are not improved by the preventorium school.

5. Such a school should be centralized in one building rather than generalized in a preventorium room in each of several schools because:

a. The plan will usually need financial support in addition to what the Board of Education can supply. This is much more easily obtained by operating a centralized plant which can be visited and described with ease.

b. A centralized school removes the possibility of stigmatizing children who would otherwise be segregated for health reasons in a regular school.

c. Curriculum modifications are so drastic that success depends upon a high degree of cooperation from the school principal. Such coöperation is much easier to obtain from one school principal and his teaching staff than from 15 or 20.

d. This school requires a decided change in the child's routine which impresses parents and assures better coöperation from the home.

e. Coordination of health centers, preventoria and sanatoria, and school health program is easier to attain through one such school than for numerous schools.

What Will Probably Cause Your Death?

WILLIAM H. DAVIS, M. D., FELLOW A. P. H. A.

Chief Statistician for Vital Statistics, Bureau of the Census, Washington, D. C.

HAVING reached any given age, what is the probability that a person will die of cancer? the probability that he will die of heart disease, etc.? These are questions of real interest to every woman and man.

In the tables given, at specified ages, the per cent probabilities of dying eventually of certain specified causes of death.

Epidemic or Endemic Diseases—The probability of a white male dying of such a cause ranges from 4.9 per cent at birth to 2.5 at ages 50 to 60 years, and is 3.0 per cent at age 90. The corresponding probabilities for white females are fractionally higher throughout life but still closely parallel the male probabilities, ranging from 5.3 at birth to 3.0 at ages 50 to 60 years and to 3.3 at age 90.

For the colored, the percentages range from 7.2 for colored females at birth to 3.9 for colored males aged 50, 60 and 90 years.

Tuberculosis—For white males at birth, the probability figure is 6 per cent and the highest probability of dying of this disease (6.7 per cent) appears at age 15, after which there is a continuous decline until at age 90 the figure is 0.2 per cent; for white females at birth the figure is 5.7 and the highest probability is at ages 1 to 15 (6.1 per cent), followed by a continuous decline to 0.2 per cent at age 90.

For colored males, the figure at birth is 11.4 and the highest probability, 13.0, appears for children 5 and 10, after which the trend is downward to 0.7 per cent at age 90, the probability figures at each age, however, always being much higher than those for white males of the same age; for colored females at birth the figure is 12.3 and the highest probability, 13.8, is for children aged 5 years after which there is a downward trend to 0.5 per cent at age 90, the probability figures at each age being much higher than for white females of the same age.

Cancer—For white males at birth the figure is 7.6 and the highest probability is at age 50 (10.1 per cent). After that age the figures steadily decline to 3.4 per cent at age 90; for white females at birth the figure is 10.6 and the highest probability figure is at age 40 (13.1 per cent) after which the trend is downward to 3.8 per cent at age 90.

For colored males the figure at birth is 2.5 and the highest proba-

bility per cent is 4.0 at age 50, and for colored females the figure at birth is 5.4 and the highest probability per cent is 8.0 at age 40.

Diabetes—For white males the figure is 1.4 at birth and 1.6 at ages 40 to 60, after which the trend declines gradually until it reaches 0.4 per cent at age 90; for white females the figure at birth is 2.1, the highest probability figure is 2.6 per cent for age 50 and the lowest figure is 0.3 per cent for age 90.

For colored males the figure at birth is 0.6 per cent, the highest probability figure is 0.8 per cent for ages 40 to 60, and the lowest, 0.3, for age 90; and for colored females the figure at birth is 0.9, the highest probability figure is 1.3 per cent for ages 40 to 50, and the lowest, 0.4, for age 90.

Cerebral Hemorrhage—For white males at birth the per cent figure is 9.1 and the probability of dying of this disease increases to 14.1 at age 70 and then decreases to 10.4 at age 90; for white females the per cent figure is 10.5 at birth followed by a trend upward to 15.4 at age 70 and then a downward trend to 11.5 at age 90.

For colored males the figure is 5.8 at birth, 10 at age 60, and 6.2 at age 90; for colored females the figure is 7.6 at birth, 13.3 at age 60 and 8.6 at age 90.

Heart Disease—For white males at birth the per cent figure is 18.2 and the probability of dying of this disease increases to 25.6 at age 70 and then decreases to 21.5 at age 90; for white females the per cent figure is 18.5 at birth followed by a trend upward to 25.4 at age 70 and then a downward trend to 21.9 at age 90.

For colored males the figure is 13.7 at birth, 20.8 at ages 50 and 60 followed by a decline to 14.5 at age 90; for colored females the figure is 14.2 at birth, 21.3 at age 50 followed by a decline to 14.6 at age 90.

Pneumonia—For white males at birth the probability figure is 7.6, the trend is then downward to 6.2 at age 60 and then upward to 7.1 at age 90; for white females the probability trend starts with 7.5 at birth, declines to 6.7 at ages 5 to 20 and then increases to 7.9 at age 90.

For the colored at birth the figure for males is 9.2 and for females 7.4 and the trend for each sex is downward to 4.7 for males aged 80 and 4.8 for females aged 90.

Nephritis—For white males the figure is 9.1 at birth, 13.1 at age 70 and 11.2 at age 90; for white females, 9.1 at birth, 11.4 at age 60 and 8.4 at age 90; for colored males, 10.3 at birth, 18.0 at age 70 and 13.2 at age 90; for colored females, 9.0 at birth, 13.5 at ages 50 to 60 and 9.2 at age 90.

Automobile Accidents—At birth, the highest probability of dying from this cause (1.5 per cent) appears for white males; at age 2 years this probability has increased to 1.7. From that age the trend is downward until at age 90 it is 0.2 per cent.

Other Forms of External Violence—For white males the figure is 8.0 at birth and 8.7 at age 2. There is then a downward trend until at age 70 the figure is 3.4 and then an upward trend to 4.4 at age 90; for white females the figure is 3.8 at birth and 4.0 at ages 1 and 2; then

Less than one-tenth of 1 per cent

there is a downward trend to 3.4 at age 50 and then an upward trend to 6.4 at age 90.

For colored males the figure at birth is 8.3 and 9.2 at ages 2 to 5 and then a continuous downward trend to 2.1 at age 90; for colored females the figure is 3.2 at birth and 3.4 at 1 year. Then follows a downward trend to 2.0 at ages 40 to 50 and an upward trend to 2.5 at age 80.

To avoid too lengthy a presentation of this subject, no further discussion will be made of the figures for white females and of the figures for the colored of both sexes beyond calling attention to the very much greater probability that the colored will die of old age or of some indefinite cause.

Commenting briefly upon a few of the figures for white males: at age 50 the probability of having the cause of your death certified as old age is 2.0 per cent, at age 70 the probability figure has risen only to 3.4 per cent, at age 80 it has reached 6.2 per cent and at age 90, 13.4 per cent.

The probability of having some ill-defined disease given as the cause of your death is never great, the figure remaining at 0.6 or 0.7 from age 1 to age 80, inclusive.

For the group, *All other causes*, the probability figure ranges from 9.9 to 9.7 from 1 year to 30 years, inclusive, after which there is a slight downward trend until the figure 8.9 is reached at age 70 and then an upward trend to 9.5 at age 90.

Some very interesting facts—and I may add some very comforting facts—are disclosed by Table II, for example:

1. The probability of dying of heart disease, cerebral hemorrhage or nephritis increases up to and including the age of 70.

On the other hand:

2. After the age of 2 years, the probability that a male will die from an automobile accident continually diminishes.

3. After the age of 2 years, the probability that a male will die from external violence continuously diminishes until up to and including the age of 70.

4. After the age of 15, the probability that a man will die of tuberculosis continually diminishes.

5. After age 50, the probability that a man will die of cancer continually diminishes.

6. After age 60, the probability that a man will die of diabetes continually diminishes.

Comparative Studies in Typhoid Stool Examinations

FRED BERRY and R. E. DANIELS

Division of Laboratories, Ohio State Department of Health, Columbus, O.

THE data presented herein were obtained during our studies to determine the relative merits of mediums recommended within recent years for typhoid stool examinations. The necessity for utilizing any method which offered an advantage was rather urgently brought upon us in the study of a milk-borne epidemic of typhoid fever in which epidemiological evidence pointed to a carrier on whom bacteriological proof was lacking. The suspected carrier had been examined in 1925 in connection with another epidemic, with negative results, and a number of specimens obtained from him in 1926, at the beginning of a second epidemic, were negative. This situation might be explained on the basis of the intermittency of many carriers, and yet the importance of this case made it necessary for us to know just what significance should be attached to our negative findings.

Furthermore, previous studies of typhoid carriers in Ohio have been largely restricted to immediate investigations of epidemics, no state-wide survey, such as Minnesota and Alabama have conducted, having been undertaken in this state. The possibility of such a survey being inaugurated made it very desirable to have data on methods of collecting and examining feces specimens which might be shipped to the laboratory. It has been customary in our laboratory when investigating a suspected carrier to have the fresh specimens forwarded by messenger or by mail to avoid undue delay. Such specimens are then examined promptly by direct plating on Endo or easin-methylene-blue agar. We have appreciated the shortcomings of such a method, especially when there was any delay in delivery of the specimen, and yet in attempting to choose a different method we were somewhat in doubt as to the respective merits of one or another procedure recommended for such work.

Teague and Clurman¹ in a study of methods for preserving typhoid stools recommended 30 per cent glycerine in saline. Wade, Kelly, and Giblin² reported very favorable results with this method, and in an extensive series of comparative tests by plating direct, and by plating from the glycerinized specimens, they found a very close agreement in

the number of positive findings of both typhoid and paratyphoid bacilli by the two methods. A number of laboratories are using the plain glycerine-saline. Havens,⁷ utilizing a brilliant green bile medium in a state-wide survey of carriers, obtained very satisfactory results. However, the use of Havens' original formula by Wade, Kelly, and Giblin⁸ did not seem to give them as favorable results as a mixture of brilliant green-glycerine-saline which they tried out in a comparative study. Later studies by Havens⁷ indicated certain improvements in his original method of preparing the brilliant green bile medium. This change was made by Havens because of the quality of brilliant green then available, and of its inferiority as compared with dyes which he used in his earliest studies.⁹

The question of a suitable brilliant green appears to be an important factor in the bile medium. This matter of variation in the effectiveness of dyes has recently been given careful study by Rakieten and Rettger¹⁰ and, as will be shown later, our own limited experiments emphasize the desirability for further study of this particular question.

One of the advantages claimed for the brilliant green-glycerine-saline by Wade and associates is that it permits a larger amount of stool to be added, a factor of considerable importance where inexperienced persons may collect the specimen. The principal advantage noted for the brilliant green bile by Havens is that it apparently permits multiplication of typhoid bacilli, thereby offering more opportunity for recovery of such organisms even when the original inoculum contains but small numbers. Because of the different results reported with these mediums, it seemed advisable to give this matter further study, especially since the question of their relative sensitiveness, as compared with direct plating, could be applied to specimens from the carrier in question, and to specimens from a considerable number of convalescents in an epidemic of typhoid fever involving more than 100 cases.

In deciding upon plating mediums for such a comparison, a selection may be made from several varieties, all of which have apparently given satisfactory results. Our choice of brilliant green Endo was based largely on the fact that it combines the universally used Endo with the brilliant green feature utilized with much success by Krumwiede and others, and because this modified Endo had given very good results in Havens' work. We selected E. M. B. agar as a second plating medium because we have found it to be so satisfactory in routine work with the colon-aerogenes group, and also because it has become widely used in this country, and is a very stable stock medium.

As already stated, this study was begun in connection with a typhoid epidemic. The stools from the convalescents who were awaiting negative laboratory tests before final discharge were utilized as experimental material. Through the coöperation of a local county laboratory,* arrangements were made to prepare direct plates from the fresh stools from these convalescents as soon as possible after collection of specimens and at the same time to inoculate each of the two fluid mediums with about $\frac{1}{4}$ gm. The latter tubes were held at room temperature and were plated at 24, 48, and 72 hours on B. G. Endo or E. M. B. agar. All cultures obtained from suspicious colonies on these plates were transferred to triple sugar slants and brought to the central laboratory for final identification. Any cultures showing typhoid or paratyphoid-like reactions on the triple sugar were tested for agglutination. If the agglutination was negative on the first test, the culture was tested again after several transfers on agar. We encountered no cultures which were inagglutinable after such transfers and which otherwise gave typical cultural tests for *B. typhosus*.

The amount of each specimen collected did not always permit making a complete comparative test, but in a total of 132 stools, the procedure outlined in Table I was carried out.

TABLE I
COMPARISON OF DIRECT PLATING AND ENRICHMENT OF STOOLS FROM RECENTLY
RECOVERED CASES OF TYPHOID FEVER

	Direct Plates		Brilliant Green Bile	Brilliant Green Glycerine-saline
	B. G. Endo	E. M. B. Agar		
Positive	15	14	20	14
Negative	117	118	112	118
Total	132	132	132	132
Per cent positive	11.3	10.5	16.9	10.5

A total of 21 additional specimens from these cases were examined but on account of insufficient material, only three mediums were used, viz., direct Endo & E. M. B. plates, and B. G. bile enrichment. In 3 of these specimens positive results were obtained in all three mediums. One was positive on direct Endo only, one was positive on direct E. M. B. and on B. G. bile, and two were positive in B. G. bile only.

The foregoing figures show that there is little choice between B. G. Endo and E. M. B. as direct plating mediums, as based on the number of positive findings. The B. G. bile and B. G. glycerine-saline show very satisfactory results as compared with the direct platings. It should perhaps be noted that the amount of inoculum was practically the same in both mediums, and that we did not attempt to study fully

* We are indebted to C. H. Waite, Bacteriologist, Lorain County, O., Health Department Laboratory for his valuable assistance, and to Dr. I. C. Riffin, Health Commissioner, for his cooperation in this work.

the question of over-inoculation which might occur under the usual field conditions. However, in order to check this point we selected a few specimens of known positive stools and inoculated B. G. glycerine-saline lightly, and heavily from the same specimen. In general, the number of typhoid colonies on the plates from these mixtures was proportionate to the amount of inoculum. The same test, applied to the B. G. bile showed overgrowth by other intestinal organisms which either obscured or prevented development of typhoid colonies when more than about $\frac{1}{4}$ gm. was used. Havens cautions against over-inoculation of his medium.

SPECIMENS FROM KNOWN CARRIER

A series of specimens from a known carrier were examined in the same manner as above except that only B. G. Endo was employed for plating. This man was under our direct supervision so that all specimens were delivered promptly and ample material was available. A total of 50 feces specimens collected within a period of several months were examined with the following results:

Total feces specimens from carrier	50
Total number found positive, one or all methods	35
Positive on direct plates, B. G. Endo	26
Positive in B. G. bile	27
Positive in B. G. glycerine	24

Classifying these still further on the basis of individual mediums, we have the following:

Direct plates	+	+	+	+	-	-	-	-
B. G. Bile	+	+	-	-	+	-	+	-
B. G. Glycerine	+	-	-	+	+	+	-	-
Number	17	5	4	0	3	4	2	15

Comparing the total positive findings on each medium we see a very close agreement between direct plating and the two fluid mediums. However, if we classify the results in the manner immediately preceding, we find that there was an advantage in using one or another of the fluid mediums along with the direct platings since there were a total of 9 specimens positive with the fluid mediums but negative with the direct plates, and 4 specimens in which the reverse was true. One cannot estimate the extent to which chance selection of material from a feces specimen might influence the result in one or another medium. It is reasonable to assume that by elaborating on the number of mediums employed, we might expect a few additional positive findings because of this chance selection and the larger amount of the original stool examined, and yet the employment of more than one fluid medium in transporting specimens would be impractical. Furthermore, our results would not justify such a plan. There were 6 specimens positive in B. G. bile which were negative in B. G. glycerine-saline

as compared with 4 specimens giving the opposite result. Both mediums were about equally reliable in this series.

Bact. aerogenes was present in practically every specimen obtained from this carrier and was a disturbing factor on direct plates and the bile medium, particularly on the 48-, and 72-hour plates. The 30 per cent glycerine-saline medium in most instances controlled any tendency to overgrowth by this organism. On the other hand, while the appearance of so many aerogenes colonies on plates from the bile medium was early noted as quite objectionable, this fact did not seriously affect the number of positive findings, especially on the plates made from the bile at 24 hours. It should also be noted here that *Bact. aerogenes* develops more rapidly and forms larger colonies on E. M. B. plates than on B. G. Endo, and for that reason the former is somewhat less desirable in specimens containing this organism.

We attempted to control the overgrowth of aerogenes by using glycerine in the bile in a concentration which preliminary tests had shown to be sufficient to partially restrain this organism as well as *Bact. coli*. This required about 14 per cent of glycerine. A small series of specimens collected weekly from this carrier were examined with direct plates, B. G. bile and B. G. bile + 14 per cent glycerine. At this time his stools contained rather large numbers of typhoid bacilli so that it is perhaps not surprising that we obtained positives by all three methods on the 12 specimens examined. In only one instance during this period were there less than about 100 typhoid colonies on direct plates.* On this day only 2 typhoid colonies were found on direct B. G. Endo, but we were successful in isolating the organisms from both liquid mediums. This was somewhat surprising in view of experiments to which we will refer later. While on the basis of these figures there was little apparent difference between the efficiency of the bile, with and without glycerine, it should be noted that whereas the former was uniformly positive on the three successive platings and kept the aerogenes organisms somewhat in check, the bile without glycerine was negative in 1 specimen at 48 hours and in 3 specimens at 72 hours, the plates from these tubes showing almost all aerogenes colonies.

ADDITIONAL COMPARATIVE TESTS

A further comparative series was carried through direct platings, B. G. bile, B. G. glycerine-saline, and B. G. bile + 14 per cent glycerine. For this study both naturally infected stools from carriers and active cases, artificially inoculated stools, and specimens obtained

* Estimates based on gross appearance of colonies, a few representative ones being selected for confirmation.

in routine examinations for possible carriers, were utilized. The results are shown in Table II.

TABLE II

	ARTIFICIALLY INFECTED STOOLS			
	B. G. Endo Direct	B. G. Glycerine- saline	B. G. bile	B. G. bile + 14 per cent glycerine
Positive	12	11	10	11
Negative	2	3	4	3
Total	14	14	14	14
	NATURALLY INFECTED AND ROUTINE STOOLS			
	B. G. Endo Direct	B. G. Glycerine- saline	B. G. bile	B. G. bile + 14 per cent glycerine
Positive	16	17	14	17
Negative	40	39	42	39
Total	56	56	56	56

This series again emphasizes the close agreement between direct plating and both of the enrichment methods employed in our earlier series as well as a rather close agreement between results in the B. G. bile with, and without glycerine. A few specimens in this series represent positive stools which were held several days after the first test, to determine the relative efficiency of the methods where the number of typhoid bacilli would presumably be constantly decreasing. In 2 specimens held 3 and 4 days respectively, the direct plates were negative and all three liquid mediums gave positive results, while in 1 specimen held 8 days, the opposite was true.

In 20 of these specimens we used the original Teague and Clurman method of 30 per cent glycerine-saline, in addition to the methods shown in Table II. Direct plates from this medium gave the same percentage of positives as the B. G. glycerine-saline, but it was noted in the majority of these positive specimens that the second and third day's platings from the plain glycerine-saline gave more typhoid colonies than the G. B. glycerine-saline.

QUANTITATIVE EXPERIMENTS

In order to determine the approximate minimum number of typhoid bacilli which could be detected by the different methods, the experiment outlined in Table III was performed. This experiment was then duplicated, using a specimen with a different content of typhoid bacilli for the inoculum. The results of the two experiments agreed as closely as one might expect when dealing with such mixtures as fecal suspensions.

It is of interest to note that with two exceptions, no positive results were obtained with the technic we employed, in any of the liquid mediums when less than about 4500 typhoid bacilli were added to 15 c.c. of each medium. It is difficult to make accurate calculations on such mixtures but in the specimen used, the ratio of typhoid colonies to other fecal types which developed on direct Endo plates was about 1-50. There

was no evidence of multiplication of typhoid bacilli in any of the liquid mediums but a gradual decrease of these organisms and a more rapid decrease of other forms. On this basis it is not so surprising, therefore, that a considerable number of typhoid bacilli must be present in the original inoculum to compensate for the dilution. A rough theoretical calculation based on the amount of sample added and the size of the loop used for plating indicated that the figures given in Table III are approximately what one might expect in the absence of any multiplication of typhoid bacilli. In short, these calculations indicate that there should not be a wide difference between positive findings by direct plates and by the use of these liquid mediums. The quantitative tests and calculations appear to confirm our results in the qualitative series.

RAKIETEN AND RETTGER METHOD

In the midst of this experiment the recent studies by Rakieten and Rettger¹ on a brilliant green enrichment medium came to our attention. Their results are indeed striking as compared with our experience in direct plating. For example, these authors report that in 204 specimens of artificially inoculated stools not a single positive was obtained on direct plates while 93 per cent of the specimens gave positive results

TABLE III
RESULTS IN DIFFERENT MEDIA INOCULATED WITH INCREASING DILUTIONS

after enrichment in brilliant green peptone broth. Although no numerical data are shown to indicate the probable density of typhoid bacilli in their specimens, it would appear that by inoculating the stools "lightly" with a typhoid culture, the bacilli were much below the concentration we have found necessary to obtain a positive result by direct plates. The Rakieta and Rettger medium is not suitable for field use since a very light inoculation is necessary, but their enrichment method might prove valuable for secondary inoculation from feces suspensions preserved and transported in glycerine. That is, one might recover typhoid bacilli from such suspensions by using their brilliant green peptone broth where direct plating from the glycerine was negative due to the small number of bacilli in the glycerine. We are making a further study of this question. In our limited experiments we have been unable to obtain a dye which gave the favorable results they have reported but we have recently received from Dr. Rakieta a sample of two lots of brilliant green which gave satisfactory results in his work. We have not had an opportunity to test these samples completely in comparison with ten other brands we had previously tried, all of which gave rather discouraging results.

PLATING MEDIUMS

Although a considerable variety of plating mediums have been recommended by different workers, it appears that Endo and E. M. B. agar have gained most favor. However, in view of the recent report of Rakieta and Rettger, it seemed advisable to make a few comparative tests with several mediums in order to determine the relative value of the two mediums we had employed. To this end in several experiments the mediums listed below were inoculated with the same amount of fecal suspensions containing typhoid bacilli, both natural and artificial mixtures. Our results, based on number of typhoid colonies, number of colonies of associated bacteria, the general type of typhoid colonies, ease of recognition, etc., may be briefly summarized as follows: Plain Endo, B. G. Endo, Plain E. M. B., Levine E. M. B., Robinson and Rettger Endo, Krumwiede B. G. agar, and Conradi-Drigalski agar plates were inoculated as uniformly as possible from the same suspensions. All plates were incubated at 37° C. and readings were made at 24 and 48 hours.

All these mediums gave reasonably satisfactory results in the development of typhoid colonies, the Conradi-Drigalski showing somewhat less colony differentiation than the other plates. The Krumwiede agar showed a tendency to more luxuriant growth of *Bact. aerogenes* in two specimens containing this organism.

The Robinson and Rettger Endo produces very pretty typhoid colonies and there is less tendency to diffusion of the red color from the acid producers. However, when compared with B. G. Endo on the basis of prevalence of other colonies and the general differentiation of these from typhoid colonies, we have not observed enough superiority of any of the other mediums to justify adoption of them in preference to the B. G. Endo. This question is largely one of personal choice based on wide experience with one or another type of medium. There is some advantage in using more than one plating medium and in this event one might utilize both the B. G. Endo and Robinson and Rettger Endo.

BRILLIANT GREEN DYES

Since so much depends on brilliant green in many of the mediums used in typhoid work, it is of great importance to have reliable and fairly uniform supplies of this dye. There is apparently considerable difference in the efficiency of different lots of brilliant green. Most workers have noted the necessity for careful titration of such dyes when added to solid or liquid mediums and have commented on these variations. Havens pointed out his inability to get uniform lots and was compelled to modify his original formula for the B. G. bile to meet this situation. Rakieten and Rettger have recently shown that only a few samples out of a number tested gave satisfactory results. These authors have also shown the necessity of controlling the pH of their peptone broth medium in order to get the most effective brilliant green action.

SUMMARY

Comparative studies were made to determine the efficiency of preservative or enrichment mediums as based on results obtained by direct platings from the same specimens. Specimens employed consisted of stools from recently recovered cases, a few active cases, a permanent carrier, and routine examination for detection of carriers, as well as artificially inoculated stools.

Very close correlation in positive results was obtained with the direct platings on B. G. Endo, B. G. bile medium, and B. G. glycerine-saline. Both of the latter mediums were found to yield about the same number of typhoid colonies although the number of associated forms was much less in the glycerine mixture. No apparent multiplication of typhoid bacilli was noted in our bile preparations.

Quantitative tests further indicated a close degree of efficiency between bile and glycerine mediums, and showed little, if any, multiplication of typhoid in the former. These tests indicated that about 4500 typhoid bacilli must be added to 15 c.c. of either medium in order to recover them at the end of 24, 48, or 72 hrs.

Comparisons of various types of plating mediums showed close agreement in the percentage of positive findings. There are, however, some other factors which influenced us in continuing the use of B. G. Endo, principal, among which is its restraining action on related forms without seriously affecting the number and character of the typhoid colonies.

Our experience parallels that of other workers in respect to the variation in different lots of brilliant green dye and emphasizes the necessity for further study of this dye as to its selective action on typhoid bacilli, and the uniformity of different lots.

ART INSTITUTE, CHICAGO, ILL.

Canned Foods and the Public Health*

YOUR committee, following up last year's report¹ on food preservation legislation in the United States, has sought to continue for the present year, the general subject of preserved foods with special reference to fruits and vegetables.

Powell² states:

The canning and preserving of food products is an important factor in household management and of even greater importance in national economy, since the conservation of foodstuffs, from the time of production and natural time of consumption to a later time, makes for a more varied and adequate diet, and that secured at a lower economic cost.

Since the interest in this subject is almost universal, some statistics relating to canned food production were gathered. In addition to analyzing these data, a very brief summing up of the present status of canned foods based on recent contributions to the subject has been attempted.

The statistics given in Table I will no doubt prove enlightening to many in that they portray the huge magnitude of the canning industry. We have included foods other than fruits and vegetables in this com-

TABLE I
COMMERCIAL CANNED FOODS
APPROXIMATE PRODUCTION IN THE UNITED STATES *
(Quantities in millions of pounds)

** Includes only products packed in slaughtering and meat packing establishments

*** Includes Alaskan production

pilation, though they come, of course, outside the scope of this committee. Many soups are partly of vegetable composition and may properly be considered a vegetable product. Some marine products are also canned with tomato sauce, olive or cotton seed oil or mustard, all manufactured plant products. Fabricated foods such as pickles, catsup, mayonnaise, jams, jellies, etc., and many glass packed foods,

* Report of the Committee on Fruits, Vegetables and their Products, delivered before the Food and Drugs Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 21, 1927.

are purposely omitted from the table because of the difficulty of obtaining reliable data concerning the amounts annually packed.

Both exports and imports of canned foods have been considered. The amount exported^{*} in 1925 was 605,000,000 lbs. or 8 per cent of the total. Milk alone makes up about one-fourth of this volume. These amounts are insignificant when compared with the domestic consumption. Other countries, except Canada, fall far behind the United States in the production and consumption of canned foods. Imports^{*} totaled 165,000,000 lbs. in 1925.

The per capita consumption of commercially canned foods using the data in Table I after allowance had been made for exports and imports and considering the population of the United States as 115,000,000, is 62.1 lbs. The per capita consumption of commercially canned fruits is 9.0 lbs. and of vegetables 28.4 lbs. Hollingshead^{*} states that canned fruit and vegetable production was 9.7 *cans* per capita in 1905; 15.1 in 1914 and 24.9 in 1925. After converting these figures to pounds they agree closely with ours.

It is estimated that the home canned food production in the United States is a billion lbs., of which 200 million lbs. are fruits and 550 million lbs. are vegetables.* The total per capita consumption of home canned foods would be 8.7 lbs.—1.7 lbs. of fruits and 4.8 lbs. of vegetables.

We do not believe we are justified in separately treating commercial and home packed foods. For all practical purposes they are similar in nutritive value, palatability and cost. Considering them together we reach a total of canned foods annually consumed per capita of approximately 70 lbs.

What effect, if any, has the consumption of this tremendous amount of canned fruit, vegetables, etc., upon the nation's health? The annual production and consumption of these foods has been rapidly increasing since the Civil War, yet we know of no impairment to the general well-being of the people resulting from it. Canned foods are cooked in hermetically sealed containers which prevent recontamination until opened. The nutritive and calorific values of the same fruit or vegetable, fresh and canned, are essentially the same. Prescott^{*} states:

While it is possibly true that dehydrated vegetables like canned vegetables, contain less antiscorbutic material than the original vegetables in the fresh condition, this does not appear to constitute an argument against their use, as, so far as can be determined, they supply the same roughage value as fresh vegetables, the same salts and the same fuel values.

To quote an editorial in our own JOURNAL:

^{*} Based on Census reports, cost of living studies conducted by Bureau of Home Economics, U. S. Dept. Agr., Reports of the Extension Service on 4-H Club Work in various states and from data compiled by the Dept. of Agricultural Econ. Mass. Agr. College.

While fresh food is, of course, the ideal, it will probably never be available as a general thing, but we can be assured that with the knowledge we have at present and are constantly acquiring, practically all foods can be preserved not only with safety, but with their nutritive properties only slightly altered.

A greater degree of heat is usually used in the canning operation than in kitchen preparation, though an increase in the temperature of cooking alone has not been shown to impair the wholesomeness of fruits and vegetables. On the contrary the heating of fruits and vegetables in a closed container without access to atmospheric oxygen serves to prevent the loss of certain accessory food factors such as the antiscorbutic vitamin. The recent investigations of Eddy¹⁰ and others have demonstrated that although different vegetables and fruits act differently, in most cases vitamins A, B, D and E are relatively uninjured while C is impaired to a greater or lesser extent by the canning process. Eddy¹⁰ in discussing his studies on canned spinach, cabbage and apples, states:

In cooking the foodstuff, the canner has not increased vitamin destruction over that produced by the home cooking of these vegetables and fruit, but has actually accomplished his purpose with less destruction in the case of the antiscorbutic factor.

The subject of food poisoning has been much discussed and investigated during the past ten years and there are several papers on this subject to be presented at other sessions of our section by specialists who have carefully studied the problem.

Outbreaks of botulism from canned foods have apparently been effectively checked by scientific investigation and control of sterilizing processes in commercial canning, and by the revision of directions for home canning so that pressure cooking is advocated for non-acid foods. The National Canners Association¹¹ has received no reports of botulism from commercially canned foods since 1925. Savage¹² in England and others have reported the presence of thermostable toxins of the paratyphoid-enteritidis group in canned foods. Due to this group's inability to form spores, it appears unlikely, except accidentally, that living cells of this group of bacteria could survive in such foods. Geiger and Benson¹³ as well as Koser¹⁴ demonstrated that this group of organisms may proliferate and even elaborate toxin in certain artificially inoculated canned vegetables, meats and marine products. Your committee feels strongly the need of further investigations upon this group of bacteria in their relation to foods.

The investigation on effect of salts of tin upon the human health has been admirably handled by the Bureau of Chemistry, U. S. Department of Agriculture, and these findings will go a long way to clear up the long existing haze surrounding this question.

Likewise the question of adulterations, either with or without public health significance, in canned or fresh fruits, vegetables and their products is being constantly investigated by various municipal, state and federal agencies. The violations are becoming less numerous than formerly. Some of the regulations have little or no bearing upon the public health. For example, the Commissioner of Agriculture for Massachusetts reported, "The percentage of adulterated or misbranded food that is produced in or brought into New England is practically negligible." Campbell, Director of Regulatory Work, U. S. Department of Agriculture, likewise has reported a reduction in the number of prosecutions brought under the Federal Food and Drugs Act from 818 in 1920, to 258 in 1927 and in seizure cases from 1407 in 1920 to 695 in 1927.

Great progress is being made on the subject of infant feeding. Accurate and dependable information should be given to the public regarding dietetics. The knowledge of the kinds, quantity and values of each food used for human consumption is eminently desirable and education along these lines is fully as important as a wholesome supply. Because of their moderate cost, average quality, accessibility and ease of preparation, canned fruits and vegetables have greatly facilitated the use of correct, palatable diets, particularly for children.

Canned foods, whether prepared in the home or in commercial canneries, regardless of the type of container, are sound, wholesome, and safe. Their continued use is commended. The advantages to the American health from the use of canned foods in the diet can hardly be over-estimated. Improvements are possible and with the aid of research and intelligent regulation, it is believed that the future of the industry is bright. The nation may have faith in its canned foods.

Test for Phenolic Tastes and Odors in Water After Chlorination

W. L. STEVENSON, FELLOW A. P. H. A.

Chief Engineer, Pennsylvania Department of Health, Harrisburg, Pa.

THE extensive installation of by-product coke ovens in the United States during the war and since, has introduced a new problem in public health work in the matter of control of disposal of phenolic waste waters produced at such plants.

Even in dilutions of 1 to 50,000,000, these wastes are capable of producing offensive tastes and odors in public water supplies derived from streams containing them.

It has been continuously observed that the consumers of such offensive water supplies refuse to drink such water even though it be bacterially safe and in lieu thereof use palatable waters obtained from springs and other sources, which in several instances have been the cause of outbreaks of typhoid fever.

Practically all of the health departments of states in the Ohio River Basin are parties to the Ohio River Inter-State Stream Conservation Agreement,* the basic principle of which is to provide for coöperation between these state health departments in the protection of public water supplies.

The outstanding instance of success of this agreement is in the installation at a large percentage of the by-product coke oven plants on the Ohio River Basin, of either works for the complete elimination of the phenolic waste waters by their use for coke quenching or the substantial treatment of the waste waters where it is not practicable to use them for coke quenching.

On February 6 the Pennsylvania State Department of Health called a conference in Pittsburgh which was attended by representatives of most of the by-product coke oven plants and some state sanitary engineers from the Ohio River Basin, the purpose being to effect more perfect coöperation between the industry and the various state health departments.

One of the important matters considered at the conference was the establishment of a tentative standard technic for testing samples of

* For report of October 18 meeting at Cincinnati, see *A. J. P. H.*, 18, 1:104 (Jan.), 1928.

water containing these phenolic wastes, and the meeting appointed a committee of expert chemists, all of whom are experienced in this work, to prepare such a technic.

Their report which is given here may prove of interest to public health workers.

REPORT OF MEETING CALLED BY PENNSYLVANIA DEPARTMENT
OF HEALTH

At a meeting held in Pittsburgh, Pa., February 6, 1928, there were representatives of the following:

Pennsylvania State Department of Health
Ohio State Department of Health
Kentucky State Board of Health
Carnegie Steel Company
Youngstown Sheet and Tube Company
Republic Iron and Steel Company
Jones and Laughlin Steel Corporation
Bethlehem Steel Company
United Gas Improvement Company
The Koppers Company

W. L. Stevenson, Chief Engineer of the Pennsylvania State Department of Health, chairman of the meeting, appointed a committee to consider the test proposed by J. W. Ellms of Cleveland, O., and report their opinion. The committee as appointed consists of F. W. Sperr, Jr., Director of Research, The Koppers Company; W. H. Fulweiler, Chemical Engineer, The United Gas Improvement Company; F. E. Daniels, Chief, Industrial Waste Section, Pennsylvania Department of Health; and O. O. Malleis, Chief Chemist, The Koppers Company.

The committee has considered the method as presented and is of the opinion that while in principle the method may be satisfactory for water works practice, it should be substantially modified to render it generally applicable. It is believed that in general a method of this sort should embody the principle of systematic dilutions with a test of each dilution, so that quantitative results can be secured. On this basis the committee has therefore drawn up a tentative method which is herewith submitted, not as final and binding, but for the purpose of inviting trial and comment. It is hoped that this method will be thoroughly examined and tried by all who are interested in the subject, and the committee would appreciate having reports of the results obtained together with any suggestions for modification or improvement that may be considered necessary.

The tentative method proposed by the committee is as follows:

1. This test is designed as a measure of the so-called phenolic tastes and odors in water after chlorination.

2. Take 500 c.c. of the material under examination, acidulate with sulphuric acid until acid to litmus, and distil off 250 c.c. Catch the distillate in a 500 c.c. volumetric flask, make up to mark with distilled water and dilute as follows: 1 to 10; 1 to 100; 1 to 1000; etc., preparing as many dilutions as may be necessary.

3. Take 200 c.c. of the distillate in the volumetric flask after making up to mark (this representing the original material undiluted) and a like amount of each successive dilution. Treat with a slight excess of chlorine water (a total of 0.3 p.p.m. of chlorine is usually sufficient). Let the sample stand for 15 minutes and then boil until excess of chlorine is removed as evidenced by test with orthotolidin.

Make the odor test by smelling the hot liquid. Make the taste test after the liquid is cooled. In the taste test, swallowing a small quantity of the liquid is the best method for revealing the presence of taste producing substances.

4. Results shall be expressed as the lowest dilution in which the taste and the odor are negative.

Pittsburgh, Pa.

February 27, 1928.

Committee

F. W. Sperr, Jr.

W. H. Fulweiler

F. E. Daniels

O. O. Malleis

NOTE: Communications relative to the method may be addressed to F. W. Sperr, Jr., Mellon Institute, Pittsburgh, Pa.

Welfare Measures for Young Workers

FOR the protection of the health of young workers in Austria, who suffered as the result of the wartime and post-war conditions, a series of measures are now in effect. A law provides 2 weeks of annual vacations with pay for all workers under 16 (1 week is required for workers over 16). Vacation houses for young workers, supported mainly by public social welfare agencies, have been established by the Ministry of Social Welfare. Persons unable to pay are maintained free of charge; others pay a nominal fee. Medical supervision is provided free.

The municipalities and the continuation-school authorities provide arrangements for athletics, hiking, and other health promoting activities, for young workers. An extensive system of vocational guidance has been established in many places. Supervision over the working conditions of apprentices and young industrial workers is exercised by workers' organizations and by factory inspectors.—*Lehrlingsschutz. Jugend-und Berufsfürsorge*, Vienna, Apr., 1928, p. 9.

WHY SMALLPOX?

FROM the point of view of relative mortality rates, smallpox has not in recent years has been of great importance in this country. In the 7 years 1921-1927 there were registered in 47 states and the District of Columbia, 3929 deaths from smallpox. (Rhode Island had no deaths from the disease during the period.) That number means an average of 561 per year, ranging from 135 in 1927 to 894 in 1924; and it is a small fraction of the total number of deaths. Moreover, each of several diseases, as well as the automobile, is annually responsible for many times the deaths due to smallpox. Nevertheless, health officers and health workers generally make more ado about the relatively few smallpox cases and deaths than they do about the much more serious measles, or pneumonia, or whooping cough.

The reason for this emphasis is clear enough to every informed person. While we do all we can to prevent these more destructive diseases, we cannot do much more than isolate patients and watch contacts. With smallpox, however, every case proclaims the failure to use well understood and practicable means of prevention. This disease, in proportion to the number of cases, is a constant reproach to the intelligence of any civilized community, since it is virtually 100 per cent preventable through systematic universal vaccination and re-vaccination. It is for these reasons that we consider it worth while to survey the smallpox situation from time to time, and to take account of our accomplishments or failures.

A compilation of the returns for 1927 shows that for the fifth successive year this country leads the world, outside of India, in the number of smallpox cases. We had 38,498 cases of smallpox as against 33,343 in 1926. And in the first 3 months of this year there were 17,242 cases as against 14,655 in the corresponding period of 1927.

Those interested in promoting the use of vaccination as a preventive of smallpox have relied for their arguments upon the striking preponderance of smallpox among the unvaccinated. For years the available records in this country show consistently about 91 per cent of all smallpox cases to be among the unvaccinated, about 7 per cent among those vaccinated more than 7 years previously, and 2 per cent among those vaccinated within 7 years, including vaccinations after exposure. Records of this kind are now available from less than half the states. It would be desirable to have all smallpox reporting include vaccinal history.

Smallpox history in this country has added to the experience of European countries another indication of the protective value of vaccination. Before the introduction of vaccination, smallpox was generally a children's disease—in severe epidemics it was often a disease of infancy. With the spread of vaccination the incidence of smallpox passed to progressively higher age levels. In recent years, however, communities in which vaccination has been neglected show a steady decline in the age level of smallpox cases. This would seem to be of sufficient significance to warrant the trouble of compiling smallpox statistics by ages as well as by vaccinal history, and by administrative areas.

The importance of suitable vaccination laws may be inferred from a comparison of the records for our various states on the basis of the different types of regulation that obtain. In 12 states with a total population of 36,680,000 (1926 census estimate), in which vaccination is required as a condition of school attendance, there were in the 7-year period 1921-1927, 25,124 cases of smallpox with 205 deaths. This is an average annual case rate of 9.8 per 100,000 of population. In 8 states in which the requirement of vaccination by officials is explicitly prohibited by law, there were, during the same period, 79,281 cases with 1277 deaths in a population of 12,133,000. This means an average annual case rate of 93.3 per 100,000, or nearly ten times as high in one group of states as in the other. In the states that leave vaccination requirements optional with local school or health authorities, or that permit "compulsory" vaccination during an epidemic, the case rate was 49.9 per 100,000.

Legislation alone, however, does not solve the problem. Last year Kentucky and West Virginia had respectively 350 and 320 times as many smallpox cases per capita of population as had Massachusetts, with similar statutes. On the other hand, Maine, with a relatively poor law, from the standpoint of public health protection, has for years maintained a low incidence of smallpox because it has not been

seriously exposed to an epidemic. Consistent law enforcement is as important as suitable statutes, but under the individualistic tradition that prevails in many parts of our country, universal vaccination, including systematic revaccination, must wait upon a better education of the public at large to an understanding and appreciation of preventive measures.

MAN'S LAST SPECTER—MENTAL DISEASE

PUBLIC health workers, in common with other observant persons, are regarding with mounting concern both the vastness of the problem created by mental diseases in this country and the meagerness of the resources for combating it. The statistics of the situation are impressive:

For example, there are virtually as many beds in hospitals and institutions for mental disease in the United States as there are beds in hospitals *for all other kinds of sickness combined*. The exact percentage is 44,* and not only is every bed occupied, but most institutions are from 20 to 35 per cent overcrowded.

Fifty thousand men and women never before mentally sick enter hospitals for the insane every twelve months.

From ten to twenty-one cents of every dollar collected by each state for taxation goes to the maintenance of public institutions for the mentally ill.

There is much more to the same effect. But these figures refer only to the institutional aspects of mental disease—the end results so to speak—an aspect many have suspected is probably of less importance than the extramural portion of the problem. In the offices of general practitioners and in the dispensaries of general hospitals are countless men and women whose ailments, given physical expression perhaps, are nevertheless really due to worries, fears, disappointments, disturbing memories, unsatisfied cravings, and the like. Their happiness and their business efficiency is frequently much impaired, and if they fail to receive early treatment, many of them later will have to be cared for in mental disease hospitals.

Still earlier in life are to be found countless children in our schools, our homes and some already in our juvenile courts, who display to the trained observer the signs of mental disease in the making. From a preventive point of view, obviously, most can be done with this latter group. For the great majority of them it is not yet too late to divert unhealthy personality traits and habits into more wholesome channels,

* As ascertained recently by the American Medical Association and others.

or to adjust the maladjusted so that tendencies towards delinquency (always a sure sign of maladjustment) or other anti-social displays of behavior may be corrected.

The difficulty in sidetracking towards health these potential victims of mental disorder is twofold: first is the obstacle of identifying them at an age when prophylactic measures can be applied with greatest hopes of success; second is the troublesome and highly complicated task of actually applying such measures. In the field of mental hygiene, identification of the potentially maladjusted means essentially *education*—education of physicians, nurses, social workers, teachers, and others, in the significance of symptoms that often enough are disguised as physical disorders, or are interpreted as manifestations of anything from “badness” or “sheer cussedness” to “original sin.” It also means education of parents, for it is the fathers and mothers usually who, with excellent intentions, create the undesirable personality traits and difficulties that characterize the “problem” child. Public health workers will do well to bear in mind that “problem children mean problem parents.”

Fortunately mental hygiene educational programs are increasing rapidly. For physicians and technical workers, fellowships and special training courses are being instituted in many of the larger medical centers. Psychiatry, with special emphasis on its social and community aspects, is making inroads on the curricula of numerous medical schools. For parents and the general public, parent-teacher organizations, mothers’ clubs and similar agencies are conducting many courses of a non-technical nature designed to bring to their audiences some of the simpler and more firmly established facts about mental hygiene and child training.

The actual measures of attack, however, in a preventive program call for the highest professional skill and special training. Child guidance clinics and similar clinical agencies, when properly conducted, probably represent the highest point yet reached in the development of machinery for dealing with maladjusted children. By the same token they also represent one of the most complicated pieces of machinery. It is no simple matter to deal wisely and efficiently with “problem” children, although it is admitted there often has been given a deceptive coloring of simplicity to the description of certain pieces of work accomplished.

Physicians, social workers, and psychologists specially trained in psychiatric technic are indispensable for such clinics, and the case load (all too often the determining factor in other types of clinics) is bound to be low if good work is to result. Of course, there are some types of

mental hygiene clinics that serve a useful purpose as diagnostic centers alone, but when treatment is included in a clinic's function, the number of cases to be effectively dealt with will necessarily remain small. This handicap has been surmounted in many of the larger child guidance clinics by making their educational possibilities second only in importance to their primary function of service to patients. Thus such clinics aid other case-working agencies in the community to acquaint individual workers with the methodology of child guidance work in order that numerous of the less complicated cases may in the future be handled directly by the non-psychiatric agency with a modicum of technical supervision. Under such a plan the low case load and comparatively high cost of a child guidance clinic are justified.

A fertile and responsive field awaits cultivation by public health workers who interest themselves in mental hygiene, especially at first in its educational aspects. The layman, often well informed about typhoid fever, diphtheria or hookworm, knows little of mental disorders, their prevention and their early treatment. To instruct him is not easy; there may be no bacilli to show under the microscope; no change in the brain to demonstrate. The causes are complex and elusive; preventive measures will not bring immediate returns, but new weapons of attack have been forged; much technical information awaits public interpretation; and renewed hope that "Man's Last Specter—Mental Disease" may some day also be vanquished is warranted by the progress already made.

CHICAGO DAILY NEWS SANATORIUM

CHICAGO—THE MEDICAL CENTER

CHICAGO'S medical institutions are among the most interesting and valuable places to be visited by public health workers, who attend the 57th Annual Meeting October 15-19. During the ten years which have passed since our last meeting in that city, vast strides have been made there not only in the development of institutions for medical treatment, education and training, but also in the facilities for and contributions to medical research of profound importance.

Long before Chicago attained prominence as a great industrial and commercial city, it became well known for achievement in the field of medicine by members of the faculty and staff of Rush Medical College, which was founded by the State of Illinois in 1837. Here Professor James V. Z. Blaney in 1847 first used "laughing gas" as an anesthetic, to be followed the next year by Professor Daniel Brainard in his successful use of chloroform.

MEDICAL SCHOOLS IN CHICAGO

Today Chicago has 4 Class A medical schools with an enrollment of students, graduating over 350 annually. These are:

- 1 Northwestern University School of Medicine
- 2 University of Chicago (Rush School of Medicine)
- 3 University of Illinois College of Medicine
- 4 Loyola University School of Medicine

On the McKinlock or downtown campus of Northwestern University and among a group of unique and modern educational buildings is the new Montgomery Ward Memorial Medical-Dental center which was opened last fall. It is housed in a mammoth 14 story building with 6 additional stories in the tower, and cost about \$8,000,000 to erect and equip—the gift of the late Mrs. Montgomery Ward. This is the tallest educational building in the world. The architecture is modern Gothic in style, and the various units are thoroughly equipped for rendering splendid service to humanity. The first 7 floors house the medical school, the next 6 the dental school. The medical clinic which now occupies the lower 3 floors will later be incorporated in the new General Hospital and Clinic to be built on the campus immediately south.

The new Medical Unit recently completed at the University of Chicago is one of the best equipped medical institutions to be found anywhere, costing in the neighborhood of \$5,000,000. It is located on the Midway on the University Campus, and is destined to be a center for medical education and research of far reaching importance and influence.

The College of Medicine of the University of Illinois has made rapid strides in recent years. The new campus is

located on Polk Street immediately adjacent to Cook County Hospital. When the projected additions to the present plant are completed, there will be a student capacity of approximately 800. The new buildings are of Gothic style in brick. The Research Hospital, the Research Laboratory, the Psychopathic Hospital and the Orthopedic Hospital have been completed. The Nurses Home is under construction; the student laboratories and dental infirmary, as well as the teaching amphitheatres are now being planned. At the present time the Research Hospital has approximately 150 beds available. The dispensary is one of the largest in the city and forms an invaluable aid for instruction of students in practical medicine. The library of the medical school is one of the largest in the country.

HOSPITAL FACILITIES IN CHICAGO

There are 135 hospitals of all types in greater Chicago, with a capacity of over 18,000 beds. About 80 per cent of these are operated for general hospital service. It is estimated that at the free

medical and dental clinics in Chicago more than 200,000 of the city's poor are treated annually.

Cook County Hospital, with 3,000 beds, is one of the largest general hospitals in the world. It is the center of Chicago's well known medical center on the near west side. Of the private hospitals St. Luke's with 650 beds is the largest. This hospital in 1927 admitted approximately 15,000 patients, of which 4,153 were qualified free cases. There were over 30,000 visits to its outpatient department. Other large hospitals in the city are Michael Reese, Presbyterian, and Mercy. The last named was established in 1849 and has been to Chicagoans all that its name implies.

The Municipal Tuberculosis Sanitarium is the largest public organization of its kind anywhere, devoted to the control of a single disease. It is located on a 160-acre tract in the northwest section of the city and has at the present time capacity for 1,225 patients. It has the most modern laboratory, hospital and surgical treatment. As a special feature it has a division devoted exclusively to

*Courtesy of
Kaufmann & Fabry Co.*

UNIVERSITY OF CHICAGO HOSPITAL

children suffering from tuberculosis. At its 8 dispensaries about 47,000 cases are registered for treatment at the present time, of which 3,000 are so-called open cases. The sanitarium has a staff of over

of the Health Department, is a 330-bed model isolation hospital with excellent equipment and doing a valuable health service.

1,100 employees and a revenue from taxation of about \$2,000,000 annually.

The Daily News Fresh Air Fund Sanitarium in Lincoln Park, where each year over 30,000 babies and about one-quarter as many mothers are treated, is a most interesting institution and worthy of study by all interested in child welfare work.

Of the strictly maternity hospitals, the Chicago Lying-In Hospital with its excellent facilities and dispensary service is the largest and probably best known in the city.

The Contagious Disease Hospital operated by the city under the supervision

ous and mental cases is operated by the State of Illinois. This is an institution which ranks among the best in America. It has about 3,000 beds.

The Illinois Central Hospital with 200-bed capacity is a splendid example of an industrial hospital.

MEDICAL RESEARCH

Some very important medical research work is being conducted in Chicago hospitals and institutions of learning. The famous discovery of the Dick test for scarlet fever susceptibility and a preventive antitoxin was made by Drs. George and Gladys Dick at the McCormick Institute of Infectious Diseases.

*Courtesy of
Kaufmann & Fabry Co.* MEDICAL-DENTAL BUILDING, NORTHWESTERN UNIVERSITY

At Cook County Hospital research work on diabetes, pernicious anemia, stomach ulcers, diseases of the heart, and the feeding of children were among the most important studies conducted last year.

In the investigative work of the scientific staff at the College of Medicine of the University of Illinois public health

problems and disease prevention are emphasized. In coöperation with the State Department of Public Health, the college staff is carrying out a series of highly important studies dealing with the adjustment of the normal body to climatic conditions; with the State Psychopathic Institute the research staff of the college has developed a new method

and treatment for tabes and paresis. The Research Laboratory has an animal hospital with complete surgical facilities, an art department for medical illustrations and a plastic studio for research workers and clinicians.

At the Chicago Lying-In Hospital extensive studies on embryology are being conducted. Valuable investigations of the use of X-ray diagnosis in obstetrics are being carried out at Northwestern.

Among the more important pieces of research being conducted at the University of Chicago Medical School are those on the metabolism of nervous tissue, infantile paralysis, the value of crystallized protein in tuberculin in combating tuberculosis, and the electrical measurement of the virility of pneumonia germs.

St. Luke's Hospital maintains a research laboratory where probably more research work is done than in any private hospital of like size in America.

DR. SCHMIDT, CHAIRMAN OF A. P. H. A. CHICAGO LOCAL COMMITTEE

THE acceptance by Louis E. Schmidt, M.D., F.A.C.S., of the chairmanship of the Local Committee for the Fifty-seventh Annual Meeting is highly gratifying to all. Dr. Schmidt has for many years been an active worker for the advancement of public health and is known as a man who does big things well. He has already effected an organization from among our Chicago and middle west members which assures us of a most successful meeting.

Dr. Schmidt is Senior Attending Urologist at St. Luke's Hospital; Professor of Genito-urinary Surgery, Northwestern University Medical School; President and Chief of Staff, Illinois Social Hygiene League; and Consulting Urologist for Michael Reese and Grant Hospitals. During Dr. Bundesen's administration as Health Commissioner for Chicago Dr. Schmidt was in charge of the Bureau of Social Hygiene and also served as a consultant for the department. He has taken active interest in all types of public health work, especially venereal diseases, tuberculosis and cancer, and has given freely of his time in advancing this work through legislation, organization and administration.

Dr. Schmidt has been a member of the American Public Health Association since 1923. He is also a member of the American Clinical Association

Moffet Studio

LOUIS E. SCHMIDT, M.D.

of Genito-Urinary Surgeons, American Urological Association and Chicago Urological Society, as well as International French and German Urological Associations.

Among those assisting Dr. Schmidt are: Arthur E. Gorman, Secretary, Isaac A. Abt, M.D., Volney S. Cheney, M.D., Thomas R. Crowder, M.D., Wm. A. Evans, M.D., Edwin O. Jordan, M.D., Arnold H. Kegel, M.D., Jacob M. Loeb, and Isaac H. Rawlings, M.D.

A. J. Chesley, M.D. (1928)

C. Hampson Jones, M.D. (1928)

E. L. Bishop, M.D. (1928)

Homer N. Calver

Sub-Committees of Committee on Administrative Practice

Executive Committee

C.-E. A. Winslow, Dr.P.H., *Chairman*, Yale University, New Haven, Conn.

Louis I. Dublin, Ph.D., *Secretary*, Metropolitan Life Ins. Company, New York, N. Y.

Homer N. Calver

Record Forms

To devise standard record forms for the use of health departments, prepare the essential records only, and attempt to group these so that the facts can easily be taken from them for statistical purposes.

George C. Ruhland, M.D., *Chairman*, 419 City Hall, Syracuse, N. Y.

I. F. Thompson, M.D.

Ira V. Hiscock

George T. Palmer, D.P.H.

Walter M. Brunet, M.D.

Mary Brownell, R.N.

Merrill E. Champion, M.D.

Advisory Member

Jessamine Whitney

Industrial Health Service

To prepare a form for the collection of the essential data with respect to health conditions and health services of industries, and to keep in touch with progress in this field.

W. S. Rankin, M.D., *Chairman*, Johnston Bldg., Charlotte, N. C.

Leonard Greenburg, Ph.D., *Secretary*, Yale University, New Haven, Conn.

Lloyd Noland, M.D.

E. R. Hayhurst, M.D.

A. J. Lanza, M.D.

Public Health Nursing

To act in an advisory capacity on surveys and assist in formulating schedules for field studies and other record forms in which nursing service is involved.

Sophie C. Nelson, R.N., *Chairman*,

John Hancock Mutual Life Ins.
Company, Boston, Mass.

Mary Laird, R.N.

Amelia Grant, R.N.

Jane C. Allen, R.N.

Rural Health Work

To prepare the Appraisal Form for Rural Health Work and its revision, at stated intervals. It is also supervising and directing a study of rural health work, which will be made during 1928 and 1929.

E. L. Bishop, M.D., *Chairman*,
State Board of Health, Nashville,
Tenn.

S. W. Welch, M.D.

John A. Ferrell, M.D.

Huntington Williams, M.D.

Joseph W. Mountin, M.D.

George T. Palmer, D.P.H.

W. S. Leathers, M.D.

Appraisal Form for State Health Work

To prepare an Appraisal Form for State Health Work along lines similar to the Appraisal Forms for City and Rural Health Work.

W. F. Draper, M.D., *Chairman*,
U. S. Public Health Service,
Washington, D. C. (To coopt
members)

Revision of Appraisal Form for City Health Work

To revise the 1926 edition of the Appraisal Form and prepare the revised form for publication in 1929.

George T. Palmer, D.P.H., *Chairman*,
370 Seventh Ave., New
York, N. Y.

James Roberts, M.D.

Allen W. Freeman, M.D.

E. L. Bishop, M.D.

George D. Lummis, M.D.

Henry F. Vaughan, D.P.H.

Philip S. Platt, Ph.D.

Organized Care of the Sick

To define the problems and guide the scope and methods of survey, which include studies of hospitals and other

organized facilities for care of the sick.

Michael M. Davis, Ph.D., *Chairman*,
370 Seventh Ave., New York,
N. Y.

George C. Ruhland, M.D.

Haven Emerson, M.D.

D. L. Richardson, M.D.

W. S. Rankin, M.D.

Advisory Members

William G. Norton

W. C. Rucker, M.D.

Model Health Ordinances

To prepare for publication an outline for a model health ordinance for the use of health officers.

Henry F. Vaughan, D.P.H., *Chairman*,
Health Commissioner, De-
troit, Mich.

Haven Emerson, M.D.

E. L. Bishop, M.D.

Huntington Williams, M.D.

James A. Tobey, Dr.P.H.

Standard Health Department Reports

To prepare an outline for Annual Health Department Reports with suggested tables and forms for presenting other pertinent data.

C. Hampson Jones, M.D., *Chairman*,
Commissioner of Health,
Baltimore, Md.

Ira V. Hiscock

Committee on Cancer

To consider the subject of cancer from a public health viewpoint.

George A. Soper, Ph.D., *Chairman*,
25 West 43d St., New York,
N. Y.

George H. Bigelow, M.D.

Henry F. Vaughan, D.P.H.

Committee to Confer with American Medical Association

To confer on relationship of practice of medicine and public health work.

Herman N. Bundesen, M.D., Chi-
cago Sanitary District, 910 S.
Michigan Ave., Chicago, Ill.

Committee on Cleanliness and Health

To review the literature preparatory to planning future studies.

Ira V. Hiscock, *Chairman*, Yale University, New Haven, Conn.

F. P. Gorham

Edward S. Godfrey, Jr., M.D.

Committee on Census of Public Health Workers

To stimulate definitions of what constitutes public health workers and conduct a census of all workers who fall within the determined classifications.

John L. Rice, M.D., *Chairman*, Department of Health, New Haven, Conn.

John F. Norton, Ph.D.

Arthur E. Gorman

C. E. Turner

George H. Van Buren

Committee on Training and Personnel

To represent the Governing Council in the matter of public health education, and to make such recommendations as may appear pertinent to the interests intrusted to this committee.

C. E. Turner, *Chairman* (1930), Mass. Institute of Technology, Cambridge, Mass.

J. G. Fitzgerald, (1928)

W. H. Welch, M.D., (1929)

John Sundwall, M.D., (1931)

C.-E. A. Winslow, Dr.P.H., (1932)

Section Representatives:

John F. Norton, Ph.D.—*Laboratory*

Thomas F. Kenney, M.D.—*Health Officers*

W. J. V. Deacon, M.D.—*Vital Statistics*

Abel Wolman—*Public Health Engineering*

E. R. Hayhurst, M.D.—*Industrial Hygiene*

F. C. Blanck, Ph.D.—*Food, Drugs and Nutrition*

Walter S. Cornell, M.D.—*Child Hygiene*

E. G. Routzahn—*Public Health Education*

Gertrude Hodgman, R.N.—*Public Health Nursing*

Sub-Committee on Health Education in Colleges

John Sundwall, M.D., *Chairman*, University of Michigan, Ann Arbor, Mich.

M. P. Ravenel, M.D.

John W. Bowler, M.D.

Harold L. Lang

J. R. Earp, M.D.

H. G. Rowell, M.D.

Glenadine C. Snow, M.D.

Ethel Perrin

Lillian A. Hudson, R.N.

Sedgwick Memorial Medal Committee

To award annually for distinguished service a memorial medal commemorating Professor William T. Sedgwick.

M. J. Rosenau, M.D., *Chairman* (1930), 65 Naples Road, Coolidge Corner, Mass.

B. L. Arms, M.D. (1928)

Lee K. Frankel, Ph.D. (1928)

E. O. Jordan, Ph.D. (1929)

Robert Spurr Weston (1929)

M. P. Ravenel, M.D. (1931)

Charles V. Chapin, M.D. (1931)

Homer N. Calver, *Secretary* (1930), 370 Seventh Ave., New York, N. Y.

Committee on Eligibility

To recommend to the Governing Council the election of Honorary Fellows, applicants for Fellowship and of State Societies for affiliation, and to perform such other duties as may be assigned by the Governing Council.

Section Representatives:

Kenneth Allen (1928)—*Public Health Engineering*

C. E. Turner (1928)—*Child Hygiene*

Philip S. Platt, Ph.D. (1928)—*Public Health Education*

H. W. Redfield, Ph.D. (1929)—*Food, Drugs and Nutrition*

Wade Wright, M.D. (1929)—*Industrial Hygiene*

Frederick F. Russell, M.D. (1929)—*Laboratory*

W. J. V. Deacon, M.D. (1930)—*Vital Statistics*

F. J. Osborne (1930)—*Health Officers*

Alta E. Dines, R.N. (1930)—*Public Health Nursing*

Committee on Membership

To elect members, associate members and Sustaining Members.

(The Committee on Eligibility has been designated by the Executive Board as the Committee on Membership.)

Committee to Coöperate with Committees of the American Engineering Council and the American Society of Civil Engineers to Secure the Commissioning of Sanitary Engineers in the U. S. Public Health Service

George W. Fuller, *Chairman*, 170 Broadway, New York, N. Y.

George T. Palmer, D.P.H.

Sol Pincus

Haven Emerson, M.D.

Committee on Dairy Products

To develop a uniform and standard procedure for the necessary protection of public health in the production, processing and distribution of these commodities, and to develop in its work contact with all other agencies having similar aims.

Henry C. Sherman, *Chairman*, Columbia University, New York, N. Y.

William H. Park, M.D.

H. W. Redfield, Ph.D.

H. A. Whittaker

Isaac A. Abt, M.D.

William H. Welch, M.D.

Committee on Federal Health Legislation

To bring the matter of correlation to the attention of President Coolidge and appropriate committees of Congress, and to coöperate with other groups studying or promoting federal health correlation, and to represent the Association in all matters pertaining

to federal health legislation.

Lee K. Frankel, Ph.D., *Chairman*, Metropolitan Life Ins. Co., New York, N. Y.

James A. Tobey, Dr.P.H.

Milton J. Rosenau, M.D.

S. J. Crumbine, M.D.

S. W. Welch, M.D.

C. Hampson Jones, M.D.

Committee on Finance

To assist the Treasurer in an advisory capacity.

Louis I. Dublin, Ph.D., *Chairman*, Metropolitan Life Ins. Company, New York, N. Y.

George W. Fuller

Michael M. Davis, Ph.D.

Editorial Committee

To assist and advise the Managing Editor of *The American Journal of Public Health*.

M. P. Ravenel, M.D., *Chairman*, University of Missouri, Columbia, Mo.

C. C. Young, D.P.H.

Louis I. Dublin, Ph.D.

E. R. Hayhurst, M.D.

James A. Tobey, Dr.P.H.

E. G. Routzahn

C.-E. A. Winslow, Dr.P.H.

Walter S. Frisbie

Merrill E. Champion, M.D.

Henry F. Vaughan, D.P.H.

Sophie C. Nelson, R.N.

Arthur P. Miller

Committee on Journal Advertising

To advise the Managing Editor in the acceptance of advertising.

Alec Thomson, M.D., *Chairman*, 1313 Bedford Ave., Brooklyn, N. Y.

Sally Lucas Jean

Charles V. Craster, M.D.

Council on Standards

To act upon reports involving standards submitted to it by the Governing Council.

George W. Fuller, *Chairman* (1931), 170 Broadway, New York, N. Y.

Henry F. Vaughan, D.P.H., *Vice-Chairman* (1928), Commissioner of Health, Detroit, Mich.

Haven Emerson, M.D. (1929)

E. O. Jordan, Ph.D. (1930)

Merrill E. Champion, M.D. (1932)

Committee on Permanency of Tenure

To take an active part in changing the method of appointments of health officers and in securing for them permanency of tenure.

S. J. Crumbine, M.D.

Matthias Nicoll, Jr., M.D.

W. H. Howell, M.D.

John L. Rice, M.D.

Committee to Coöperate with Director of Census

To act as an advisory committee to coöperate with the Director of the Census in regard to vital statistics.

Charles V. Chapin, M.D., *Chairman*, Superintendent of Health, Providence, R. I.

Haven Emerson, M.D., *Secretary*, 437 W. 59th St., New York, N. Y.

Irving Fisher, Ph.D.

Committee on Ventilation

To study the relationship of ventilation to health, particularly in schools.

Louis I. Harris, M.D., *Chairman*, Commissioner of Health, New York, N. Y.

Thomas Duffield—*Public Health Engineering Section*

Joel I. Connolly—*Public Health Engineering Section*

Leonard Greenburg, Ph.D.—*Industrial Hygiene Section*

C.-E. A. Winslow, Dr.P.H.—*Industrial Hygiene Section*

S. Josephine Baker, M.D.—*Child Hygiene Section*

Charles H. Keene, M.D.—*Child Hygiene Section*

Committee on Chautauqua Health Program

To represent the Association in the organization of a rural health program in coöperation with Chautauqua sys-

tems, the Milbank Memorial Fund and others.

S. J. Crumbine, M.D., *Chairman*, 370 Seventh Ave., New York, N. Y.

H. E. Kleinschmidt, M.D.

Bertrand Brown

E. H. Marsh, M.D.

Donald B. Armstrong, M.D.

Temporary Organizing Committee for the West

To develop organization and to advise on problems particularly affecting the Western members of the A. P. H. A.

W. C. Hassler, M.D., *Chairman*, Department of Health, San Francisco, Calif.

E. T. Hanley, M.D., *Vice-Chairman*, 300 Public Safety Building, Seattle, Wash.

John J. Sippy, M.D., *Secretary*, Health Department, Stockton, Calif.

J. L. Pomeroy, M.D.

George Parrish, M.D.

Robert A. Peers, M.D.

H. B. Hommon

William P. Shepard, M.D.

H. E. Young, M.D.

F. D. Stricker, M.D.

W. F. Cogswell, M.D.

Advisory Member

James J. Waring, M.D.

Central Program Committee

To prepare programs for annual and other meetings of the Association and to establish standards for these programs.

Herman N. Bundesen, M.D., *President*, 910 S. Michigan Ave., Chicago, Ill.

Homer N. Calver, *Secretary*, 370 Seventh Ave., New York, N. Y.

Section Representatives:

C. C. Young, D.P.H.—*Laboratory*

C. Hampson Jones, M.D.—*Health Officers*

George H. Van Buren—*Vital Statistics*

Arthur E. Gorman—*Public Health Engineering*

Eugene L. Fisk, M.D.—*Industrial Hygiene*

J. H. Shrader, Ph.D.—*Food, Drugs and Nutrition*

H. H. Mitchell, M.D.—*Child Hygiene*

Ira V. Hiscock—*Public Health Education*

Mary Laird, R.N.—*Public Health Nursing*

SECTION COMMITTEES AND SECTION COUNCILS

The following is a list of the section committees. Where information has been supplied by the section secretaries an indication of the purpose of the committee is given.

HEALTH OFFICERS SECTION

Section Council

C. Hampson Jones, M.D., *Chairman*, Commissioner of Health, Baltimore, Md.

A. J. Chesley, M.D., *Vice-Chairman*, Old Capitol, St. Paul, Minn.

E. L. Bishop, M.D., *Secretary*, State Health Commissioner, Nashville, Tenn.

Alton S. Fell, M.D. (1928)

Louis I. Harris, M.D. (1928)

A. J. Douglas, M.D. (1928)

F. G. Curtis, M.D. (1929)

James Roberts, M.D. (1929)

H. L. Rockwood, M.D. (1929)

LABORATORY SECTION

Section Council

C. C. Young, D.P.H., *Chairman*, Department of Health Laboratory, Lansing, Mich.

W. H. Frost, M.D., *Vice-Chairman*, 615 N. Wolfe St., Baltimore, Md.

W. D. Stovall, M.D., *Secretary*, State Hygienic Laboratory, Madison, Wis.

Leonard M. Wachter (1928)

Friend Lee Mickle (1928)

E. Marion Wade (1929)

T. G. Hull (1929)

Committee on Standard Methods

E. O. Jordan, Ph.D., *Chairman* (1929), University of Chicago, Chicago, Ill.

John F. Norton, Ph.D., *Secretary*

(1929), University of Chicago, Chicago, Ill.

Norman MacL. Harris, M.B. (1929)

Roger G. Perkins, M.D. (1928)

William H. Park, M.D. (1928)

George W. McCoy, M.D. (1928)

W. H. Frost, M.D. (1930)

Leonard M. Wachter (1930)

Augustus B. Wadsworth, M.D. (1930)

Referees

A. M. Buswell, *Chemical Water Analysis*

Chester T. Butterfield, *Bacterial Water Analysis*

W. C. Purdy, *Microscopical Water Analysis*

Robert S. Breed, Ph.D., *Bacterial Milk Analysis*

F. P. Gorham, *Shellfish Analysis*

G. F. Reddish, Ph.D., *Methods for Testing Disinfectants*

T. R. Crowder, M.D., *Air Analysis*

W. A. Manheimer, *Bacterial Examination of Swimming Pools*

S. DeM. Gage, *Chemical Examination of Swimming Pools*

Anna W. Williams, M.D., *Diagnosis of Diphtheria—including virulence, intracutaneous tests, etc.*

Ruth Gilbert, M.D., *Wassermann Test*

Committee to Confer with A. P. H. A. Committee on Dairy Products

Robert S. Breed, Ph.D., *Chairman*, N. Y. Agricultural Experiment Station, Geneva, N. Y.

S. H. Ayers

W. D. Dotterer

Committee on Appraisal Form

Friend Lee Mickle, *Chairman*, State
Department of Health, Hartford,
Conn.

C. C. Young, D.P.H.

Ruth Gilbert, M.D.

Aubrey H. Straus

E. K. Kline, Dr.P.H.

Committee on Abstracts in the Journal

C. C. Young, D.P.H., *Chairman*,
Department of Health Labora-
tory, Lansing, Mich.

Ruth Gilbert, M.D.

I. S. Falk, Ph.D.

W. D. Dotterrer

Charles Krumwiede, Jr., M.D.

Committee on Program

C. C. Young, D.P.H., *Chairman*,
Department of Health Labora-
tory, Lansing, Mich.

W. D. Stovall, M.D.

Friend Lee Mickle

*Committee to Draw Up Curriculum in
the Education of Laboratory Workers*

C. C. Young, D.P.H., *Chairman*,
Department of Health Labora-
tory, Lansing, Mich.

W. R. Stokes, M.D.

T. G. Hull

VITAL STATISTICS SECTION

Section Council

George H. Van Buren, *Chairman*,
Metropolitan Life Ins. Company,
New York, N. Y.

F. M. Register, M.D., *Vice-Chair-
man*, Bureau of Vital Statistics,
Raleigh, N. C.

John O. Spain, *Secretary*, Bureau
of the Census, Washington, D. C.

E. S. MacPhail (1928)

W. A. Plecker, M.D. (1928)

Haven Emerson, M.D. (1929)

W. Thurber Fales, Sc.D. (1929)

*Committee on Forms and Methods of
Statistical Practice*

To suggest revised standard certi-
ficates of births and deaths for each
decade and outline a few standard
tables to promote uniformity in the

presentation of data.

William H. Davis, M.D., *Chairman*,
Bureau of the Census, Washing-
ton, D. C.

William H. Guilfooy, M.D.

Sheldon L. Howard

F. M. Register, M.D.

J. V. DePorte, Ph.D.

A. W. Hedrich

*Committee On Accuracy of Certified
Causes of Death and Its Relation to
Mortality Statistics and the Interna-
tional List*

To study the reliability of statements
of causes of death and make recom-
mendations concerning the decennial
revision of the International List.

Haven Emerson, M.D., *Chairman*,
437 West 59th St., New York,
N. Y.

William H. Guilfooy, M.D.

E. H. Lewinski-Corwin, Ph.D.

Louis I. Dublin, Ph.D.

Charles Norris, M.D.

William H. Davis, M.D.

George H. Van Buren

Wilmer R. Batt, M.D.

W. J. V. Deacon, M.D.

John O. Spain

Advisory Members

W. T. Longcope, M.D.

W. R. Williams, M.D.

Committee on Registration Affairs

To report on the progress made in the
registration of births and deaths.

William H. Davis, M.D., *Chairman*,
Bureau of the Census, Washing-
ton, D. C.

Carl F. Raver, M.D.

Stewart G. Thompson, D.P.H.

W. Thurber Fales, Sc.D.

A. A. Whittemore, M.D.

Committee on Public Health Climatology
To review studies of the influence of
climate on health and encourage in-
creased efforts in this field.

E. W. Kopf, *Chairman*, Metropoli-
tan Life Ins. Company, New
York, N. Y.

Kenneth Allen
 John S. Fulton, M.D.
 Lowell J. Reed, Ph.D.
 I. S. Falk, Ph.D.
Advisory Member
 R. B. Watson

Committee on Contributory Causes of Death

To analyze statistics on this subject and study methods in selecting the contributory cause in cases where three or more causes are reported on the same death certificate.

George H. Van Buren, *Chairman*,
 Metropolitan Life Ins. Company,
 New York, N. Y.

John O. Spain
 W. A. Plecker, M.D.
 John W. Trask, M.D.
 M. O. Heckard, M.D.
 Stewart G. Thompson, D.P.H.
Advisory Member
 Albert G. Love

Committee on Vital Statistics Training

To serve principally in an advisory capacity for any person seeking information regarding a course of instruction in vital statistics.

W. J. V. Deacon, M.D., *Chairman*,
 Dept. of Health, Lansing, Mich.
 Raymond Pearl, Ph.D.
 C.-E. A. Winslow, Dr.P.H.
 Edwin W. Kopf
 William H. Davis, M.D.
 James S. Elston

Committee to Aid Completion of Registration Area Before 1930

To make extensive efforts to improve the registration of births and deaths in states where the registration is not now up to the standard required for admission into the registration area.

Louis I. Dublin, Ph.D., *Chairman*,
 Metropolitan Life Ins. Company,
 New York, N. Y.
 Frederick L. Hoffman, LL.D.
 William H. Davis, M.D.
 Wilmer R. Batt, M.D.
 Blanche M. Haines, M.D.

R. C. Williams, M.D.
Advisory Members
 Jessamine S. Whitney
 W. R. Redden, M. D.
 George W. Ehler

Committee on Joint Causes of Death

To consider ways of improving and making more uniform the methods used in selecting one cause of death from a group of two or more causes reported on the same death certificate

William H. Davis, M.D., *Chairman*,
 Bureau of the Census, Wash-
 ington, D. C.

George H. Van Buren
 William H. Guilfooy, M.D.
 John O. Spain

Committee on Proper Allocation of Records

To consider the working out of a plan whereby births and deaths will be charged according to the usual place of abode instead of the place of birth or death.

J. V. DePorte, Ph.D., *Chairman*,
 N. Y. State Department of
 Health, Albany, N. Y.
 William H. Davis, M.D.
 Stewart G. Thompson, D.P.H.
 W. J. V. Deacon, M.D.
 Walter F. Willcox, Ph.D.
 William H. Guilfooy, M.D.
 George H. Van Buren

FOOD, DRUGS AND NUTRITION SECTION
Section Council

J. H. Shrader, Ph.D., *Chairman*,
 901 Municipal Building, Balti-
 more, Md.
 Henry C. Sherman, *Vice-Chairman*,
 Columbia University, New York,
 N. Y.
 Carl R. Fellers, Ph.D., *Acting Sec-*
retary, Massachusetts Agricul-
 tural College, Amherst, Mass.
 J. C. Geiger, M.D. (1928)
 Carl R. Fellers, Ph.D. (1928)
 Harry W. Redfield, Ph.D. (1929)

Committee on Beverages

All beverages except milk are con-

sidered as falling within the scope of this committee. Sanitation, adulteration, food value, container sterilization, and methods of manufacture and laboratory examination of beverages are considered.

T. J. King

M. J. Dooling, D.V.M.

Committee on Fruits, Vegetables and Their Products

Raw and preserved fruits and vegetables, as well as their products may properly be considered under this committee. The public health aspects of the production, transportation, marketing and consumption of raw, canned, dried or refrigerated fruits and vegetables are very important.

Henry M. Loomis, *Chairman*, 1739

H. St., Washington, D. C.

Carl R. Fellers, Ph.D.

Chester A. Darling, Ph.D.

Committee on Cereals and Their Products

The production, manufacture, distribution, food value, adulterations, bacteriological and chemical studies of cereals and such products as flour, starch, malted and prepared breakfast foods and their public health aspects are important.

F. C. Blanck, Ph.D., *Chairman*,
Bureau of Chemistry, Wash-
ington, D. C.

E. V. McCollum, Ph.D.

D. B. Jones, Ph.D.

Committee on Meat, Fish and Shellfish

The usual health aspects of meats, fish and shellfish, such as sanitation, disease transmission, purity, decomposition, food value and laboratory examination are of the greatest importance in the work of this committee.

Carl R. Fellers, Ph.D., *Chairman*,
Mass. Agricultural College, Am-
herst, Mass.

F. A. Korff

A. C. Hunter, Ph.D.

Committee on Dairy Products and Eggs
Milk, butter, ice cream, cheese, milk drinks, malted milk, evaporated and condensed milk, dried milk powders, baby preparations, shell eggs, frozen and desiccated eggs and all kinds of egg preparations properly come within the scope of this committee.

Harry W. Redfield, Ph.D., *Chair-
man*, R. F. D. No. 1, Mendham,
N. J.

D. B. Peck, M.D.

E. M. Pickens, D.V.M.

Martin J. Prucha, Ph.D.

W. B. Palmer

W. H. Price, M.D.

Committee on Nutritional Problems

The food value, calorific, vitamin, and other basic studies on all kinds of foods; effect of adulterants, minerals, etc., on food value; nutritional diseases and metabolism disturbances are the problems of this committee.

Henry C. Sherman, *Chairman*,
Columbia University, New York,
N. Y.

E. L. Fisk, M.D.

D. B. Jones, Ph.D.

T. P. B. Jones

C.-E. A. Winslow, Dr.P.H.

PUBLIC HEALTH ENGINEERING SECTION

Section Council

Arthur E. Gorman, *Chairman*, 6743
Olympia Ave., Chicago, Ill.

Stephen DeM. Gage, *Vice-Chair-
man*, 310 State House, Provi-
dence, R. I.

George W. Putnam, *Secretary*, De-
partment of Health, Chicago, Ill.

INDUSTRIAL HYGIENE SECTION

Section Council

Eugene L. Fisk, M.D., *Chairman*,
25 W. 43d St., New York, N. Y.

Frank L. Rector, M.D., *Vice-Chairman*, 823 Case St., Evanston, Ill.

Emery R. Hayhurst, M.D., *Secretary*, Ohio State University, Columbus, O.

A. J. Lanza, M.D. (1928)

T. R. Crowder, M.D. (1928)

Volney S. Cheney, M.D. (1929)

Carey P. McCord, M.D. (1929)

George M. Price, M.D. (1929)

Elizabeth B. Bricker, M.D. (1929)

Committee on Industrial Anthrax

To keep close watch on human anthrax in America and report to the Section.

Henry F. Smyth, M.D., *Chairman*,
University of Pennsylvania, Philadelphia, Pa.

Volney S. Cheney, M.D.

S. Dana Hubbard, M.D.

Stanley H. Osborn, M.D.

Committee on Industrial Morbidity Statistics

To report at the Annual Meetings.

Wade Wright, M.D., *Chairman*,
Metropolitan Life Ins. Company,
New York, N. Y.

Frank L. Rector, M.D.

George H. Van Buren

Committee to Assist in Extension of Interstate Control of Poisons and Hazardous Substances Other Than Foods

Henry F. Smyth, M.D., *Chairman*,
University of Pennsylvania, Philadelphia, Pa.

Leonard Greenburg, Ph.D.

Frank L. Rector, M.D.

Committee on Standard Practices in the Problem of Compensation of Occupational Diseases

A. J. Lanza, M.D., *Chairman*, Metropolitan Life Ins. Company,
New York, N. Y.

Henry K. Kessler, M.D.

Bernard S. Coleman

George M. Price, M.D.

May R. Mayer, M.D.

Elizabeth B. Bricker, M.D.

R. R. Sayres, M.D.

E. R. Hayhurst, M.D.

J. G. Cunningham

Committee on Lead Poisoning

To report annually to the Section on the status and control of lead poisoning.

Carey P. McCord, M.D., *Chairman*, 62 Groton Bldg., Cincinnati, O.

Robert A. Kehoe, M.D.

Committee on Industrial Fatigue

To report at the Annual Meetings.

Eugene L. Fisk, M.D., *Chairman*,
25 West 43d St., New York, N. Y.

Wade Wright, M.D.

Derric C. Parmenter, M.D.

L. R. Thompson, M. D.

Frederick B. Flinn

E. R. Hayhurst, M.D.

Committee on Volatile Solvents

To report at the Annual Meetings.

Alice Hamilton, M.D., *Chairman*,
Harvard School of Public Health,
Boston, Mass.

Elizabeth B. Bricker, M.D.

Committee on Silicosis

To report at the Annual Meetings.

E. R. Sayres, M.D., *Chairman*, U. S. Bureau of Mines, Washington, D. C.

E. R. Hayhurst, M.D.

A. J. Lanza, M.D.

Committee on Skin Irritants

To report at the Annual Meetings.

Henry F. Smyth, M.D., *Chairman*,
University of Pennsylvania, Philadelphia, Pa.

CHILD HYGIENE SECTION

Section Council

Harold H. Mitchell, M.D., *Chairman*, 370 Seventh Ave., New York, N. Y.

J. H. Mason Knox, M.D., *Vice-Chairman*, 16 W. Saratoga St., Baltimore, Md.

Carl E. Buck, Dr.P.H., *Secretary*,

ASSOCIATION NEWS

DR. GEIGER RETURNS TO CALIFORNIA

J. C. Geiger, M.D., formerly epidemiologist of the U. S. Public Health Service and Assistant Commissioner of Health in Chicago, Ill., has been appointed Associate Professor of Epidemiology in the University of California Medical School and Hooper Foundation for Medical Research. During 1913-1916 Dr. Geiger was epidemiologist for the California State Board of Health. While in Chicago, Dr. Geiger also served on the faculty of the University of Chicago.

Dr. Geiger is a Fellow of the A.P.H.A. and a member of the council of the Food, Drugs & Nutrition Section. He has made valuable contributions to the research field on botulism and food poisoning.

DR. WILINSKY HONORED

Friends of Dr. Charles F. Wilinsky gave a dinner in his honor in Boston, Mass., the evening of May 22. The occasion was Dr. Wilinsky's appointment as director of the new Beth Israel Hospital, Boston. He has taken a leave of absence from the Health Department where he has been serving as Deputy Health Commissioner, and he has resigned as president of the Boston Health League. Dr. Wilinsky is a Fellow of the A.P.H.A.

Dr. George Bigelow was a stimulating

and gracious toastmaster. Brief addresses were made by those who have been associated with Dr. Wilinsky in his work in the Health Department, the Health League, the Medical Society, and in the new hospital.

Ex-Mayor Curley on behalf of his friends, presented Dr. Wilinsky with a magnificent colonial clock.

DR. BINGHAM DIES

Arthur Wallace Bingham, M.D., president of the medical board of the Willard Parker Hospital, New York, N. Y. for the last 5 years, and since 1923 a member of the A.P.H.A. died June 10 at his home in New York City of heart disease after an illness of 3 months. Dr. Bingham was 55 years old. He was graduated from Yale University in the class of 1896 and later obtained his medical degree from the College of Physicians and Surgeons, Columbia University. For 10 years he was visiting surgeon to Willard Parker Hospital. Dr. Bingham received high commendation from the public health committee of the New York Academy of Medicine in its report of 1925 for his success in the care of contagious diseases. The May, 1927, issue of the *American Journal of Public Health* carried an article by Dr. Bingham, "Community Control of the Acute Infections," written in collaboration with Joseph J. Gallagher.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Health Program Following Mississippi Flood—The total area affected in the spring of 1927 by the flood waters of the Mississippi and its tributaries represents 20,000 square miles inhabited by approximately 908,200 people. Emergency sanitation was provided by the American Red Cross in 149 concentration camps caring for 330,000 people. Assistance was rendered by the various state health departments, U. S. Public Health Service, the Rockefeller Foundation, and by neighboring states. It is estimated that in all the states in the flooded area 469,442 individuals were immunized against typhoid fever, receiving three inoculations, and 137,340 individuals were vaccinated against smallpox, before July 1, 1927.

During the spring and early summer of 1927 an effort was made to control malaria by means of screening the homes of malaria carriers. Nearly 7000 homes were screened in a period of approximately 90 days.

Since July, 1927, 78 counties have established health departments, and over 200 full-time health workers have been employed in such departments. Training schools were organized for the practical teaching of field public health work to prospective health officers, nurses and inspectors. The principal school was located at Indianola, Miss. The health program in each case was instituted along the same standard lines as enjoyed elsewhere.

The diseases which showed the greatest increase during the postflood period were pellagra and malaria. To combat the increase in pellagra dried brewer's yeast was distributed, and to control malaria the screening of homes occupied

by carriers was attempted, as was likewise, the free distribution of quinine.—J. G. Townsend, *The Full Time County Health Program Developed in the Mississippi Valley Following the Flood. Pub. Health, Rep.*, 43: 1199, (May 18), 1928.

Rabies Control in Kansas City—The Health Department in Kansas City, Mo., immunized, free of charge, from January 27, 1927, to April 1, 1928, 19,486 dogs. There were immunized by the veterinarians in this city, perhaps, 5,000 or 6,000 dogs. We have used the single injection method. Two hundred and eighty persons were given antirabic treatment in our clinic in 1925; 331 in 1926; 132 in 1927, and 12 the first 4 months of 1928. Our laboratory made the examination of 189 heads in 1926; 150 in 1927, and 5 in the first 4 months of 1928.

Our Department of Inspection and Sanitation, in coöperation with the laboratory and veterinary department, have recently completed a study or recheck and it is their opinion that the single injection is very successful and the cases of rabies developing in animals, after treatment, are practically unknown to this department. We have 2 reported cases, but in each of these cases the dog had been exposed before being given treatment.—Ernest W. Caviness, Personal communication, May 10, 1928.

Inoculation Against Diphtheria—The winter's epidemic of diphtheria in Paris has clearly shown the value of Ramon's anatoxin. This is obtained by heating diphtheria toxin and adding to it 40 per cent commercial formalin in the

proportion of 1 in 2000. Treated in this way the toxin becomes atoxic, while keeping its antigenic properties. Antitoxin is obtainable in boxes of three ampules each containing 2.0 c.c. the liquid being tinted green. Either two or three injections are given, the first being 0.5 c.c. and the second 1.0 c.c. given a fortnight after the first. In 87 per cent of cases the Schick reaction becomes negative after the second, which makes a third injection unnecessary; if required it is given after an interval of a week. In case of urgency it may be desirable to produce a passive immunity with purified serum.

Zoeller and Ramon now recommend vaccination via the nasal mucous membrane for patients who object to subcutaneous inoculation. Against diphtheria they protect the patient by instilling concentrated glycerinated antitoxin into the nose every second day. Two and sometimes three courses of treatment, lasting 6 days with intervals of a week to a fortnight between them, have proved sufficient to convert a positive into a negative Schick reaction. The method has the advantage of being easy to apply and of not provoking any vaccinal reaction, but it is less precise than subcutaneous inoculation and fairly large doses of antigen are required. Local vaccination is said to be as suc-

cessful in preventing dysentery, tetanus, and scarlet fever, as it is in the prophylaxis of diphtheria. Inoculation Against Diphtheria, *Lancet*, CCXIV: 1041 (May 19), 1928.

Serum Reactions—A study was made of a series of 237 patients with diphtheria and scarlet fever who received antitoxin at the Willard Parker Hospital, New York, N. Y. Of this number 171 were diphtheria cases and 66 were scarlet fever cases, and 164 gave a history of never having had any serum injections; while 45 had had a previous therapeutic dose, and 28 had been immunized with diphtheria toxin-antitoxin. Of those who had not had previous serum injections, 22 or 13.4 per cent, experienced a serum reaction. Of the 45 who had received antitoxin previous to the present illness, 8 or 17.8 per cent, had serum reactions. Of the 28 patients who gave a history of having been immunized against diphtheria, 4, or 14.3 per cent, gave serum reactions. These were all cases of scarlet fever. Previous administration of toxin-antitoxin appears to have little or no effect on subsequent serum treatment.—Sophie Spicer, The Effect of Previous Administration of Antitoxin and Toxin-Antitoxin on Serum Reaction, *J.A.M.A.*, 90: 1778 (June 2), 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Relation of Atmospheric Humidity to the Deterioration of Evaporated Apples in Storage—The work recorded here was undertaken for the purpose of studying the effect of the humidity of the storage room on the keeping quality of dried fruits, in particular evaporated apples. Five well known varieties were collected having uniform moisture content. These were stored at temperatures of 20° to 30° C. (68° to 86° F.) under conditions of humidity varying from complete saturation to complete dryness. In all cases the fruit absorbed or gave up moisture until equilibrium with the surrounding air had been maintained. It was found that with relative humidities of 18.8 per cent or less the fruit retained the original color, odor and flavor throughout the entire storage period of three years. Relative humidities between 47 and 80.5 per cent resulted in brownish discoloration, rancid odor, and bitter flavor. These changes were evident within one year with fruit having a moisture content between 9 and 10 per cent. If it is assumed that these changes are the result of enzymic action, the enzymes are evidently not destroyed by treatment of the fruit with sulphur dioxide, sodium chloride or by heating to 80° C. before drying. Relative humidities higher than 80.5 per cent resulted in the rapid development of molds and yeasts sufficient to destroy the material within a few months. Treatment preliminary to drying, such as sulphur fumes, dipping in 2 per cent salt solution, or heating in steam to 80° C. did not eliminate discoloration at low humidities or the development of yeast and mold growth at higher humidities. It was also found that deterioration was

much more rapid in apples which contained highest acidity and lowest content of sugar. Fruit with a moisture content of 24 per cent (a maximum recognized by the U. S. Department of Agriculture for evaporated apples) is in approximate equilibrium with air having a relative humidity of 75 per cent at 30° C. (86° F.). Moisture is rapidly absorbed when the relative humidity rises beyond this point.—Charles W. Culpepper and Joseph S. Caldwell, *J. Agri. Res.*, 35:889 (Nov. 15), 1927.

Nutritional Anemia on Whole Milk Diets and Its Correction With the Ash of Beef Liver—Reference is made to an earlier article (*J. Biol. Chem.* 72:299, 1927) showing the correction by the addition of the ash of lettuce or cabbage of experimental anemia induced in rabbits by feeding whole milk—Fe₂O₃ diet. The present work records experiments using the ash of beef liver as the corrective. Rats of 50–60 g. in weight were placed on screens on a sole diet of whole milk until hemoglobin readings indicated that the animals were anemic. Since a whole milk diet results in depriving the animals of iron, a chemically pure solution of ferric chloride was made from standard iron wire and this was fed at a level of 0.5 mg. of Fe per animal per day without correcting anemia. Then beef liver and beef liver ash were tried. The former was dried at 65° C. for 67 days and then ground to powder which was fed by suspending it in whole milk and in amounts such as to introduce 0.5 mg. of iron, equivalent to that fed as FeCl₃. The ash of the liver was incinerated in a furnace at 650°–750° C., after which it was digested in

hydrochloric acid, diluted and filtered from insoluble residue. The filtrate, after concentration, was fed at a level of 0.5 mg. of iron daily and administered by stirring it into the milk. It was found that when iron in this amount obtained from liver was fed in either of the materials prepared prompt correction of anemia resulted and the hemoglobin was restored to normal, indicating that nutritional anemia of this type is due to an inorganic deficiency. A more detailed paper is to be prepared later.—J. Waddell, C. A. Elvehjem, H. Steenbock and E. B. Hart, *Science*, 67:139 (Feb. 3), 1928.

Vitamin A Deficiency and Urolithiasis—The author calls attention to the statement of Osborne and Mendel to the effect that out of 857 autopsies on rats on a vitamin A deficient diet they found calculi 81 times. McCollum and Simmonds found that calculi have occurred frequently in animals whose diets contained an abundance of vitamin A but were faulty in other respects and attributed the formation of calculi to general debility rather than to specific nutritional deficiency. These conclusions led the author to observe the rats in the laboratory of the Netherlands Institute of Nutrition as to the presence of calculi in the kidneys, the urinary tract and the bladder. The results of examination of 886 rats, 405 males and 481 females, are given. Among them were 241 which never suffered from vitamin A deficiency and in which no cases of calculi were recorded. The balance, 645 yielded 197 cases of calculi and these rats had been fed on vitamin A deficient rations as evidenced by chemical examinations. In addition to phosphate calculi were found those composed of calcium, ammonium magnesium phosphate and calcium oxalate, the latter occurring with McCollum's rachitogenic diet. It was observed that calculi on a vitamin A deficient diet formed rapidly, for example, after exper-

imental diets of 9 days, 12 days, 17 and 19 days, and 3 weeks the formation of calculi proved very common. The author concludes that there is a connection between vitamin A deficiency and the formation of phosphate calculi.—E. C. van Leersum, *J. Biol. Chem.*, 76:137 (Jan.), 1928.

Nature of the Protein Surrounding the Fat Globules in Milk—Details are given of the methods employed by the authors to determine the identity of the substance or hull surrounding the fat globules in milk. The result indicated a protein substance of rather constant composition having a low ash content and very closely related to, if not identical with casein. This relationship is supported by the determination of sulfur, phosphorus and tryptophane content of the hulls which agree almost exactly with the casein content of these substances. A significant difference between the character of the hull-protein and the casein is the lower solubility and the darkening of the hulls when dissolved in sodium hydroxide which indicates the possible contamination of the hulls with some unknown substance.—R. W. Titus, H. H. Sommer and E. B. Hart, *J. Biol. Chem.*, 76:237 (Jan.), 1928.

Antiricketic Substances. VII. Biochemical and Spectroscopic Studies on Purified Cholesterol—Work recorded here as a result of biological tests and the examination of absorption spectra led to the conclusion that the ergosterol-like substance in cholesterol which is readily activated is in fact ergosterol itself. A description is given of the Shipley line test and the position of the three absorption bands of cholesterol and ergosterol are confirmed—293.5, 282, and 270 mu. A fourth band common to each was discovered at 260 mu. Activation by ultra-violet rays was possible in the case of cholesterol specially treated with charcoal or bro-

mine for the removal of ergosterol. The activatability is due either to cholesterol itself or to an impurity persisting after three purifications with bromine. Details of the biological and spectroscopic technic are given, together with a plate showing the absorption spectra of cholesterol and ergosterol selected from 200 exposures.—Charles E. Bills and Edna M. Honeywell, *J. Biol. Chem.*, 76:251 (Jan.), 1928.

Vitamins in Canned Foods — Strawberries—Previous papers on this subject indicated that the chief factor in destroying vitamin C in the canning of foods is oxidation, and that after the preliminary destruction subsequent heating has little effect. Four experimental lots of strawberries were canned; stemmed strawberries being put into the cans filled with water boiled and subsequently cooled to 120° F. Cans were then exhausted at 190° F. for 12 minutes, closed, cooked in boiling water for 8 minutes and then cooled in cold water. The four lots, before processing, varied in temperature and the manner in which they were kept. These lots were tested for vitamin C content approximately 15 months after the date of canning. Growth curves of 3 guinea pigs are shown indicating the value as a source of vitamin C of canned tomatoes, raw strawberries and canned strawberries. It was found that strawberries are a rich source of vitamin C similar to tomatoes, furnishing a protection against scurvy in guinea pigs in daily amounts of 2 to 3 g. Canned strawberries, after having been canned a year had a similar vitamin C content to the fresh berries. The explanation ascribed is that strawberries contain considerable oxygen. Compared with tomatoes, strawberries are only about one-fortieth as rich in vitamin A and about one-fourth as rich in vitamin B.—E. F. Kohman, W. H. Eddy, and Nellie Halliday, *J. Indust. & Eng. Chem.*, 20:202 (Feb.), 1928.

Biological Values of Certain Types of Sea Food. II—Vitamins in Oysters—Vitamins A, B, and D in oysters were studied by feeding tests on albino rats. The oysters were obtained from Chesapeake Bay, ground while frozen and kept frozen during the period of experimentation. It was found necessary to feed in this form owing to the fact that experiments indicated that dehydrated fresh oysters had lost nearly all of the original vitamin B property and a very significant proportion of vitamin A during the dehydration which apparently also changed the chemical composition of the oysters. In the case of rats which had developed xerophthalmia, raw frozen oysters were fed at the 3.5, 2 and 1 g. level daily. The 3.5 g. level caused a growth response and the chart indicated that the 2 g. level is sufficient to cure xerophthalmia, although more slowly than the higher amount. The 1 g. level had little effect either on the growth or on curing xerophthalmia. The vitamin B content of frozen oysters was determined by curative and prophylactic methods and the feeding was conducted at 1, 2, 3.5 and 5 g. level daily. Five g. resulted in excellent and uniform growth rate but somewhat slower rate with the 3.5 portions, lower levels being inadequate to maintain weight. By the prophylactic method, the 5 g. level maintained a satisfactory growth rate for 60 days but failed to maintain it for a longer period. The animals suffered a rapid decline at the end of 12 weeks. This was shown to be due to insufficient vitamin B which affords a comparison of results obtained by the curative and prophylactic methods.

The "line test" method was used to determine vitamin D. Five g. of oysters daily for 10 days resulted in slight calcification comparable with that produced by 4 mg. of a good grade of cod liver oil. This daily quantity of oysters resulted in complete calcification in 20 days. Ground, dried oysters were

used in experiments to determine the presence of the reproductive factor. As a result of this investigation the oyster was found to be deficient in this respect.

The article contains a discussion as to the reasons for the destruction of vitamins A and B during dehydration which is ascribed either to bacterial or enzymic action during the time required, usually about 30 hours, or to the effect of traces of certain metallic elements since oysters are known to contain copper, lead, arsenic, and zinc.—D. Breese Jones, J. C. Murphy and E. M. Nelson, *J. Indust. & Eng. Chem.*, 20:205 (Feb.), 1928.

Growth-Promoting Value of Cod Liver Oil Irradiated by Sunlight and the Mercury Vapor Lamp—In order to obtain further evidence as to the possibility of increasing the antirachitic potency of cod liver oil, three groups of six young rats each were fed a basal rachitic ration supplemented by 1 per cent of Norwegian cod liver oil dissolved in 2 per cent of corn oil. The cod liver oil for one group had received no treatment, for another had been exposed to direct solar rays, and for a third had been irradiated with a mercury vapor lamp at a distance of 2 ft. for 20 minutes. Two other groups serving as controls received the basal ration alone, in one case untreated and in the other irradiated with a mercury vapor lamp in the same manner as the cod liver oil.

As judged by the growth of the different groups through the experimental period of 8 weeks, the irradiated cod

liver oil was no more effective than the untreated oil. That growth was a measure of antirachitic vitamin rather than vitamin A was thought to be demonstrated by the fact that the group receiving the irradiated basal ration made the greatest gains in growth.—A. L. Daniels and L. M. Brooks, *Proc. Soc. Exper. Biol. & Med.*, 24 9:971,972, 1927. Abstr., *Exper. Sta. Rec.*, 58:90 (Jan.), 1928.

Influence of the Age of a Milk, on the Result of Pasteurization—Cultures on gelatin and agar-agar were made of samples of fresh milk and of the same milks after sterilizing by heating for $\frac{1}{2}$ hr. at 62–63° F., followed by rapid cooling, and a comparison was made of the total number and of the relative proportions of the different kinds of bacteria in the fresh and sterilized milks. Similar tests were made on the milk after keeping for periods varying from 2 to 8 hrs. at temperatures from 8° to 30° F. The results show that the number of bacteria surviving pasteurization, as well as the percentage of these calculated on the total number present in the unpasteurized milk, are greater for the milks which have been kept for a time than for those which were sterilized at once in practice, it is therefore preferable to sterilize a milk as early as possible and then to keep it cool, rather than to keep it in cold storage and sterilize later.—A. Wolff, *Milch. Zentralb.* 11:233–238, 1927. Abstr. *Brit. Chem. Abstr.*—B, 47:33 (Jan. 6), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

Progress Reports on Two Studies
—It cannot be denied that there is urgent need for more intensive studies of the principles on which public health is based. Consequently it is encouraging to follow the course of two such studies, preliminary reports of which will be briefly summarized below.

The first, entitled "Principles of Measurement Used in the School Health Study" is by Dr. Raymond Franzen, Research Director, School Health Study, American Child Health Association. Dr. Franzen first discusses observation and interpretation and points out that every judgment must have some kind of measurement as its basis and illustrates by three possible ways of estimating the nutritional status of a child:

1. A physician may consider various aspects of the child and come to a general rating which unconsciously summarizes all of his considerations.

2. The physician may estimate each of about fifty items, such as "subcutaneous tissue over the biceps," "subcutaneous tissue over the triceps," "size of calf muscles," and so forth, as being satisfactory or unsatisfactory, and then base his judgment upon a conscious summary of these estimates.

3. He may measure each of the items that he wishes to consider with some instruments like caliper and steel tape and then base his judgment upon the material secured by this investigation.

Passing to measures which have been used to evaluate school health experience, enumeration is made of three: First, available records; this is unsatisfactory on the score of inaccuracy and lack of adaptability. Second, rating scales and appraisal forms, is unsatisfactory as measuring practices and not results. The third consists of tests "constructed in order to achieve particular ends." Such tests must meet cer-

tain criteria: (1) different examiners must be able to obtain the same results with the same children; (2) "the items which together form a particular test should be alike in the essential we are measuring and different in all unimportant and chance ways"; (3) "each item of the test must have a known diagnostic emphasis"; and (4) "the quality measured must serve a useful purpose."

The second study is one carried on in Syracuse, N. Y., by the New York Commission on Ventilation during the school year 1926-27. The summary of results is given by Mr. Duffield under the title "Effects of Mechanical and National Ventilation on the Health of School Children."

Six schools were chosen—3 ventilated by modern mechanical methods and 3 by forty- and fifty-year old furnace-heated, naturally ventilated buildings.

Various records were kept: a temperature record; and an attendance and health record covering (a) the pupils on the active roll, (b) the pupils present, (c) the pupils present with respiratory illness, (d) the pupils absent with respiratory illness—the latter term including coryza, pharyngitis, tonsillitis, laryngitis, bronchitis, pneumonia, tuberculosis, grippe, etc.

Without going into details, which should be read in the original report, it may be sufficient to say that Duffield considers the "gross or crude results" of the study show: that the mechanically ventilated schools showed excesses of 47 per cent in total absenteeism, 67 per cent in absenteeism due to respiratory illness, of 80 per cent in the pupil sessions attended with respiratory illness; and of 77 per cent in respiratory illness among the pupils present and absent.

The summing up in the form of conclusions follows in the words of the writer of the paper:

If our original data had been based on the more reliable foundation of diagnosis of respiratory illness by competent persons, and had our follow-up of absentees been such as to preclude the possibility of falsification of cause of absence, and had the numbers of individuals included in our study been greater, we should be warranted in making the unqualified assertion of what this preliminary study strongly suggests, namely, that natural ventilation has some inherent virtue which mechanical ventilation does not possess, or that mechanical ventilation involves some harmful influence from which natural ventilation is free.

The high correlation between respiratory illness absenteeism in the mechanically ventilated schools and precipitation has been shown. For those interested in the mathematical relationship, it should be stated that with the seasonal trend of respiratory illness removed, the correlation ratio for the period February 4 to April 14 is $+0.82 \pm 10$, apparently both reliable and significant, whereas the corresponding figures for the naturally ventilated schools are $+0.35 \pm 0.27$, demonstrating no significant correlation.

It shall be our endeavor through further studies to remove the doubts that cloud the findings of this preliminary study and to demonstrate whether the high rate of air change is the causative agency in the excess of respiratory illness absenteeism in the mechanically ventilated schools.—

Raymond Franzen, Ph.D., *Child Health Bull.*, Jan., 1928; Thomas J. Duffield, reprinted from *J. Am. Soc. Heat. & Vent. Eng.*

Dental Prophylaxis—The January issue of the *Journal of the American Dental Association* includes a symposium of four papers by Drs. Quinby, Adair, Charters and Spalding on Dental Prophylaxis, presented at the Seventh International Dental Congress in 1926. Excerpts appear below:

It may be of interest to quote the opinions of a number of men recognized as leaders in the field of preventive dentistry:

It was because the profession did not clean teeth that the dental hygienist has come into existence. (T. P. Hyatt).

I have considered the future of the dental hygienist only in connection with the public schools Thus it seems that the public schools . . . which reach all the children of all the people offer the largest contact with the public. It is safe to say that 90 per cent of all constructive health work for the future will be done through this agency.

From this conception of the interdependence of mouth health and general health . . . the field of the dental hygienist must be twofold:

First—There is the . . . prophylactic treatment and instruction in the hygiene of the mouth to aid in prevention of dental caries and gingivitis as far as it is possible, by cleanliness and artificial gum stimulation.

Second—There is educational service concerning these laws of general hygiene which promote the development and growth of a normal healthy body.

It is this work that must eventually influence the coming generation. Only through education can we hope to secure better teeth and a higher degree of immunity to dental disease. (A. C. Fones).

Conclusion: Periodic cleaning of the teeth is an important part of the program of preventive dentistry for both children and adults among the American population.

Gum massage is an important agency for the building of oral health.

The introduction of the child to dental service should be such as will enlist his coöperation.

All three of these things can be accomplished as well by the dental hygienist as by the dental practitioner, and at less expense to the community.—

The Dental Hygienist, E. Melville Quinby, D.M.D., *J. Am. Dental Assn.*, Jan., 1928.

Prophylaxis has been of such tremendous import and has given such far-reaching results that the work has spread and expanded until it is almost outside the dental ranks, and is almost as big as our profession itself.

The dental hygienists are conquering the children and grown people where we failed, but some of us will be laid on the shelf with the great dominating idea which has gripped the disciples of Smith, that prophylaxis is the greatest thing in dentistry and the best thing which could be done for the patient; that its proper application requires more skill and knowledge of conditions than any other branch, and it should, for this reason, be administered by the dentist himself.

Oral prophylaxis, as often practiced, is a complete and miserable failure. This declaration but analyzes the fact that, when properly practiced with a spirit of knowledge and

enthusiasm, it is the greatest success of all things yet embodied in our profession.

If we find a dentist with a dirty, stained set of teeth, and the same condition in his wife and children, he knows prophylaxis is a failure. If we find an office where no talk or demonstration on preventive dentistry is given the patients, or the dentist has a hygienist in a corner of his office, just for a side-show, we know that no interest in the subject exists here. If you see a dentist or hygienist who uses a pot of ordinary pumice with a dental engine, you will probably see why prophylaxis is a failure. If you see a dentist or hygienist who fails to teach oral hygiene facts to his patients, you will also view another failure.—

Oral Prophylaxis as Practiced—A Failure or Success? Robin Adair, D.D.S., *J. Am. Dental Assn.*, Jan., 1928.

Today, we are in an era of preventive dentistry, when the most important dental procedures are cleaning, and the use of methods planned to produce sound teeth and to save them, rather than to repair them or provide substitutes after irreparable damage. In such preventive work, I believe that we are beginning to appreciate what the toothbrush can do more than we have ever done in the past.

It is my opinion that more good can be accomplished by the dentists, in this present age at least, in teaching patients how to clean the oral cavity correctly, than dietitians can possibly accomplish in trying to regulate the diet to such an extent that the toothbrush will not have to be used nor will it be considered a necessity.

The attention of the patient should be called to the fact that there are five surfaces to every tooth that should be brushed, mesial, distal, occlusal, buccal and lingual. The average person brushes two surfaces, namely, the buccal and lingual, and firmly believes that he has done a perfect job, when in reality he has not even started. The majority of people have learned incorrectly how to brush their teeth through instructions from the platform and toothbrush drills, or by reading toothbrush or tooth paste advertisements.—

Immunizing Both Hard and Soft Mouth Tissue to Infection by Correct Stimulation with the Toothbrush, W. J. Charters, D.D.S., *J. Am. Dental Assn.*, Jan., 1928.

Cleaning Teeth, as such, by the dentist, having in mind as an objective, clean teeth only, is a menial task, unworthy the time of any refined or educated person, and for which there could be no commensurate compensation. However, if the process is a step in the

education of the patient in personal mouth hygiene, or in the establishment of oral health, or the treatment of oral disease, or for the sick, it assumes a different aspect, that of a dignified professional service. Repetition of this service is not justifiable after a state of health is once established. Everyone should do this work for himself, and patients ought to be impressed with their own obligations in this matter. Until we recognize these facts, we will always be looking for a way out of the task, being especially enthusiastic about passing the responsibility on to others.

If the individual dental hygienist is more interested and better qualified to impart knowledge concerning these subjects than the individual dentist, by all means allow her to do so, since thoroughness, a natural teaching ability and a broad training in psychology and hygiene are requisites.

The fundamental character of dental prophylaxis is made up of the following principles: It is inseparable from other branches of dentistry. Education in dental prophylactic measures is of prime importance. An operation on the teeth involves a consideration of the periodontium. The correction of incipient dental and periodontal lesions is essential. Thoroughness is indispensable. Perseverance is a requisite; as is also a consciousness of the truth of prevention in dentistry.—

The Fundamentals of Dental Prophylaxis, Grace Rogers Spalding, D.D.S., *J. Am. Dental Assn.*, Jan., 1928.

Maternal Damage—Dr. Louise McIlroy, Royal Free Hospital, London, in her address on Maternal Mortality, as reported in *National Health*, emphasized the much neglected topic of maternal damage from childbirth, claiming that maternal mortality figures could never be other than "misleading so long as no mention was made either of the women whose health was irretrievably ruined by childbearing or of those who died a few months after confinement from causes to which the conditions of labour had directly or indirectly contributed. What had to be considered was not merely whether the death rate rose or fell, but whether the damage rate was higher or lower as the years went by."

Maternal death is a tragedy always, but to send a mother home from the hospital broken in health, totally unable

to meet home conditions with any success, is surely almost equally serious.

Dr. McIlroy was very decided in her belief that needed dental attention should not be postponed until after confinement—both because of the “very definite danger of general toxemia arising from neglected teeth,” and because if left until confinement is over it is apt to be again neglected.

Pregnancy occurring in the tuberculous can rarely be allowed to continue in her opinion, because of rapid deterioration of health after confinement.

Cancer of the cervix was included among the dangerous conditions resulting from unskilled obstetrics. Statistics showed that cancer of the cervix was almost wholly confined to women who had borne children, though there were no figures available to show that the danger was increased by the number of pregnancies.—*National Health*, Jan., 1928.

Bacteriology of Dried Powdered Milk Preparations Used in Infant Feeding—It would seem that we have an undue feeling of security as to freedom from bacteria of dried powdered milk preparations.

The Dicks report an investigation undertaken in connection with a study of an epidemic of enteritis which occurred in an institution in which the infants received artificial feeding composed largely of dried protein milk.

The method of taking the cultures from the samples of the preparations of dried milk is given in detail.

A feeding prepared for one institution of protein milk contained 22,000 bacteria per c.c., of which 11,000 were green-producing streptococci.

In the feeding prepared in the other institution from protein milk there were 9,000 bacteria per c.c. with 7,000 green-producing streptococci.

The conclusions are that the methods of manufacture do not destroy the bacteria in the milk and that bacteria remain

viable in the product; also the preparation of the powdered milk feeding without boiling or pasteurization allows the bacteria in the product to persist in living form in the feeding.—George F. Dick, M.D., and Gladys H. Dick, M.D., *Am. J. Dis. Child.*, Dec., 1927.

Incidence of Tuberculosis Among New Zealand School Children—In 1926 a valuable investigation of the incidence of tuberculosis in 1,268 school children (ages 4 to 15 years) from country and town schools was undertaken in two districts in New Zealand. The objects of the piece of work were as follows:

1. To find the amount of tuberculosis occurring.
2. To learn what association exists between subnormal nutrition and latent tuberculosis.
3. To select groups of children requiring special provision.
4. To estimate the treatment necessary, either prophylactic or curative.

The children were given the Moro percutaneous tuberculin test. Positives were further investigated by means of the X-ray and chest examination by a specialist. Comparisons made with other data which are given in some detail “show the figures obtained to be trustworthy.”

There were 14.1 per cent who gave a positive reaction to the Moro test; 8.3 per cent of the European country children were positive as against 15.8 per cent in town children. The last showed marked difference also. Twenty-five per cent of the Maoris, all of whom lived in the country, gave a positive reaction apparently because of the close association with infected persons.

In the Wellington district the country children under 7 years were all negative, while 7.3 per cent of the town children under 7 years were positive. The influence of family history and exposure to infection, past history and environment were all gone into in considerable details.

"There was no indication of the influence of milk supply, about half the children having been supplied with pasteurised milk and half from private dairies."

As to nutrition, the positive and negative groups showed subnormal nutrition to be equal. Twenty-six per cent of the cases were 5 per cent or more below normal in each group but the positive group gave a slightly higher figure for superior nutrition—8.9 per cent whose nutrition was 10 per cent or more above normal. (The term "normal" was used rather than average in this connection.)

The parents of each positive child were personally interviewed and in those cases requiring treatment special lines of

treatment were laid down at a further interview.

Open-air régime, health camps, immunization by inunction with tuberculin ointment (already started in the Canterbury district) and ultra-violet light are recommended in appropriate cases.

Conclusions:

This work is yet in its infancy, but we have been able to select a group of children who will require watching until the age of twenty-five, and a smaller group requiring special care by the means most appropriate to the individual cases. This, if carried out more extensively in the future, should constitute a valuable means of prophylaxis, whereby the incidence of tuberculosis may be considerably lessened.—Mary Champtaloup, M.D., *Med. Off.*, Dec., 1927.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

New York State Public Health Nursing—Mathilde S. Kuhlman, R. N., says "coöperating with nurses of various charitable, industrial, and private organizations, the division of public health nursing gives the citizens the best of nursing care."

The public health nursing division in the state of New York in 1913 consisted of 4 nurses. It is now made up of a nurse director, assistant director, 63 supervising nurses, and an office force of 3 stenographers and 1 clerk. This expansion is commensurate with the increasing number of public health nurses in the state, there now being 1200 instead of the 135 in 1913.

Many of the public health nurses throughout the state are supported by funds from cities, towns, and counties under the health officers or boards of education. Every public health nurse employed from public funds must meet certain educational requirements. Each one must be a graduate nurse, not less than 21 years of age, registered by the

Board of Regents of the New York University, and shall have had a postgraduate course in public health nursing. To be in the state's service, she must also have had a year's experience in actual public health nursing. Civil service examination is required for county and state service and for some cities.

The state is divided into 15 sanitary districts, and a supervising nurse is assigned to each district to assist the nurses in that territory, and to know the nursing service in her district. Some of the remaining nurses connected with the State Department of Health are assigned to the various divisions for special work connected with these departments. Sheppard-Towner funds employ 8 full-time and 30 part-time nurses in 29 communities for maternity, infancy, and pre-school child work for a demonstration period.

An attempt is made to keep the state nurses and other public health nurses in public positions informed as to any new, approved methods of work. To this end

the staff nurses of the State Board of Health observe individually the work as it is carried on by such centers as the Maternity Center Association, the East Harlem Nursing and Health Demonstration, and others. Moreover, through federal funds the State Department of Health maintains a teaching center for maternity, infancy and child hygiene nursing. Nurses who are to take care of this work for the state must spend two or more weeks here for observation and training. (Other qualified public health nurses in or out of the state may avail themselves of this center.)

To help nurses to keep informed, there is a correspondence reading course, conducted by the New York University and the Bellevue Hospital Medical College. Each public health nurse is also provided with all the literature pertaining to maternal and child hygiene, communicable diseases, and social hygiene, published by these different departments.

To interest her still further in her chosen profession, there is held once each year a conference of health officers and public health nurses called by the State Health Commissioner. Needless to say, other conferences are held locally.

The incidence of poliomyelitis has given rise to special problems, that of caring for those unfortunate individuals afflicted by paralysis. For this purpose, the state has a staff of nurses under the direction of an orthopedic surgeon for follow-up work.

Not only does a close relationship and fine spirit of coöperation exist between the public health nurses employed by official agencies and the state Division of Public Health Nursing, but this is also found between the nurses employed by private organizations and the state. Thus, throughout all New York State, public health nurses work together to promote the health of the people.—Mathilde S. Kuhlman, "New York State

Public Health Nursing," *Nation's Health*, Nov., 1927. B. J. B.

New Social Hygiene Agency—
The importance of venereal disease is a public health problem of great magnitude. Too often voluntary agencies are handicapped by the absence of a specified local, social hygiene association to which to turn, and the result is that this phase of public health nursing is inadequately dealt with, or disregarded entirely. Health workers in New York City have been faced with situations where their health efforts would have been of more avail had there been such an association.

The adoption of a social hygiene program by the New York Tuberculosis and Health Association has been announced, with a statement of the proposed objectives. The objectives are summarized as follows:

To discover infected cases and keep them under qualified treatment by aiding physicians, clinics, hospitals, and institutional and social agencies, and by maintaining an information service to the public.

To discourage and prevent treatment by medical charlatans, druggists, and unqualified practitioners.

To support the health department in securing the reporting of venereal disease and data, in epidemiological studies, in studies of adequacy and distribution of facilities, and in securing adequate appropriations.

To promote health education in coöperation with sex educational agencies.

To supplement law enforcement agencies by advice and authoritative information.

Nurses who have been asking themselves how best to aid those working for the prevention and control of venereal diseases have here perfectly definite, clear-cut answers to their questions.—*J. Social Hyg.*, Nov., 1927.

The Thirteenth Annual Report—
One of the stabilizing forces in Public Health Nursing in the State of Massachusetts is the Association of Directors of Public Health Nursing Organizations. The thirteenth annual meeting was held in Boston, November 16, 1927, and ac-

According to the *Annual Report*, 71 organizations were represented by 251 board members, this being the largest attendance since the association was organized.

The developments of public health nursing in its relation to the duty of the board members and the recognition by board members for the opportunity for discussion and exchange of experiences, is a need which this association has tried to meet, both in county and annual meetings. Following the trend of the times, a committee was appointed by the Public Health Section, Massachusetts State Nurses Association, to meet with a similar committee appointed by the Massachusetts Association of Directors of Public Health Organizations, to consider ways and means of effecting closer relations and affiliations.

The Report of the Study of Child Welfare questionnaires for the entire state is included with brief statements of the subject matter dealt with by those who gave the addresses. The report may be obtained from Agnes T. Marvin, Secretary, Hingham, Mass.

NOTE: Similar organizations exist in a few other states. The value of such organizations to public health nursing is inestimable. We call attention to the fact that the invitation to the directors to participate in nursing activities came from the public health nurses of the state of Massachusetts.

The Types and Treatment of Heart Disease—As long as heart disease yearly exacts its toll, interest is naturally attracted to this subject. Samuel A. Levine, M. D., has made a valuable contribution to the literature on this subject.

Dr. Levine discusses briefly the various important types of heart disease; points out the essential differences between them; and mentions some of the principles of treatment. The important types of heart disease in the order of their development during life are congenital heart disease, rheumatic, thyroid, syphilitic, and degenerative or senile heart disease.

In congenital heart disease certain portions of the heart, or main blood vessels leading to it, may be incompletely or imperfectly formed. Some of the deformities may not cause any sign of heart disease. Again, they may cause dyspnea, spells of suffocation, weakness, or even poor mental or physical development. Little can be done to prevent or treat congenital heart disease. However, as such children are very susceptible to infections, they should be carefully guarded from exposure to infectious diseases.

The second type of heart disease results from rheumatic infections. This usually manifests itself by acute inflammatory rheumatism or Saint Vitus's dance. Sometimes the signs are not so noticeable, being only tonsillitis, sore throat, or the pains familiarly known as "growing pains." Acute inflammation of the heart may be the first symptom of heart disease. While damage to the heart does not always result from rheumatic infection, many times serious organic changes are produced. In many cases, the patient may recover from the infection with no apparent damage to the heart, but this may show itself twenty years or more afterwards.

There are two parts to the problem of the treatment of rheumatic heart disease.

1. The care of the acute attack of rheumatic infections.
2. Care where congestive heart failure occurs.

In the first case, the patient is kept in bed and the parts affected and the patient made as comfortable as possible. Some form of salicylates is generally given for the rheumatic pains. The treatment of the second class is mostly concerned with the proper administration of digitalis. Restful nights are necessary. When edema exists, it is well to start the patient on 200 c.c. of milk four times a day, which may be increased to a soft or semi-solid diet. The use of salt should be restricted. Ordinary nurs-

ing care is an important part of the treatment, as anything which aids in the diminution of the physical and mental burden of the patient aids his recovery.

Once the diagnosis of thyroid heart disease is made, a course of treatment follows which will prepare the patient for surgery. All the measures advocated for the treatment of heart failure should be applied with the addition of the administration of Lugol's solution.

Syphilis produces a certain type of heart disease. It usually affects the aortic valves causing aortic insufficiency. This results, usually, years after the initial infection. The outstanding feature of this disease is pain in the chest and also dyspnea. When this aortic type of patient shows heart failure, he is not able to live much longer than a year or two. Treatment is the same as that for any kind of heart failure with the addition of the measures which will treat the underlying disease, syphilis. Marked distress in breathing may be relieved by hypodermic injections of morphine or caffeine.

Degenerative or senile heart disease is the last to be considered. This is usually caused by the changes going on in the blood vessels. "When the arteriosclerosis is essentially limited to arteries, there results a condition called angina pectoris. When angina pectoris is not present, the generic term 'chronic myocarditis' is used to describe the condition." In cases of angina pectoris, death frequently takes place suddenly. However, this is not always the result. Treatment then depends upon the sever-

ity of the attack and the economic status of the patient. He is better off in bed for a month or so. Some form of nitrites or the inhalations of an amyl nitrite pearl should always be used for an attack. The patient should rest, particularly after meals.

In chronic myocarditis the heart gradually becomes inefficient. The strength of each beat is impaired. Dyspnea, edema of the organs, engorgement of the liver, and an accumulation of blood in different parts of the body develop. The patient should be kept in bed and the usual nursing care given.

Not much is known about the prevention of heart disease. Improved general nutrition will probably diminish the instance of rheumatic fever in the young. It would be well for children and adolescents to be over normal weight and for adults after 40 to be below normal weight.—The Types and Treatment of Heart Disease, Samuel A. Levine, M. D., *Am. J. Nurs.*, Nov., 1927. B. J. B.

State Aid for Connecticut Towns—Westbrook is the first town to start a new public health nursing service under the new state law which gives state aid in proportion to the amount of town tax receipts. Westbrook has appropriated its pro rata share for this service; a public health nurse has been appointed; and the work is now functioning.

The town of Cornwall has made application for the subsidy for public health nursing, its share having already been appropriated.—State of Connecticut *Health Bull.*, Nov., 1927.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Talking and Planning for the Section—Members of the Section Council with other interested members of the Public Health Education Section gathered in New York for a day and a half in February. Plans were laid for the Chicago program and exhibits, and for other section activities. All present were enthusiastic over the value of talking over program possibilities and plans for extending the services of the section. It is hoped to hold such a conference every year.

Public Health Education Institutes—The Section Council agreed to conduct a limited number of one- or two-day institutes or conferences. These might be held under the auspices of state health organizations or by university extension departments. A moderate fee will be charged to secure regular attendance and to reduce the expense to the sponsoring body. Invitations to hold institutes should be addressed to the chairman, Professor Ira V. Hiscock, Yale University, New Haven, Conn.

Talking It Over Among Yourselves—The round tables being conducted by the New York Committee on Publicity Methods (see *A. J. P. H.* Feb., 1928, p. 242) have been so interesting and practical that we hope health workers in different cities will adopt the idea. And at least one such session might be held in connection with any state meeting of health workers. Details will be supplied by Evart G. Routzahn, 130 East 22d St., New York, N. Y.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

"Media of Publicity" for Medical Societies—The following were offered by Dr. Frank C. Hammon, Chairman, Committee on Lay Education, Medical Society of Pennsylvania: "Newspapers (distributed direct and through syndicates and county societies; magazines, distributed through agencies or direct); labor organizations; fraternal organizations; ministerial organizations; men's clubs and service organizations; women's clubs; churches, radio; movies; stores, libraries; schools and colleges; trolley cards; industrial corporations; coöperation with insurance companies; inauguration of 'Health Week' by county medical societies; health-examination clinics in connection with 'Health Week'; county fairs and other exhibits; state farm show; coöperation with Anti-tuberculosis Association, welfare federations, cancer and heart associations, and any health organization; coöperation with state, county, and city health departments; coöperation with nurses, druggists, and dentists' associations; inauguration by county societies of permanent health-examination clinics; coöperation with hospitals and hospital associations." —*Atlantic M. J.*, Aug., 1927.

Education Against Cancer—"Not only must the laity and the medical profession be educated, but dentists and nurses must be informed of what they should know," says *Campaign Notes*, American Society for the Control of Cancer, 25 West 43d St., New York, N. Y., Jan., 1928. Under "Suggestions for a State Campaign for the Control of Cancer," the following methods are listed: "For the public: newspaper articles and editorials; lectures; moving

pictures; exhibits; radio talks; pamphlets, posters and booklets; personal instruction of patients by physicians, dentists and nurses; clinics. For the medical profession: papers read before meetings of societies; lectures by speakers from a distance; conference of members of hospital staffs; clinics; pamphlets, reprints, etc." *Free*.

Small Type in Books—"Is there any way of 'getting under' or making war against publishers who produce books with small type? As a seller of books for boys and girls, I have been literally bombarded with complaints from customers about them. Many refuse to consider books with excellent material just because of poor print. . . . The printers of such books are not only defeating their own purposes as to sales, but they are sacrificing the eyes of boys, girls, and grown-ups."—Letter from Bookshop for Boys and Girls, Boston, in *Saturday Review of Literature*.

Write protests to publishers of books issued in too small type. Get material for a press story (or suggest the idea to a local editor) by interviewing book sellers as to the relative saleability of books in small type. Use large type in your own leaflets and booklets.

Education in a Measles Epidemic—Observations in the midst of measles epidemics in a number of cities prompted the following educational or publicity suggestions:

Enlightening information as to the nature of measles, reasons for changing former regulations, etc., should be given out and the responsibility of the public in the prevention of deaths made clear.

What may be expected of the health department by way of help—such as free medical attention if the family cannot afford a physician, visiting nursing service, and hospital facilities—should also be publicly known.

If any foreign newspapers are available they should be used freely.

A special effort should be made to reach

parents of preschool children through educational visits and by pamphlets.

—Measles a Community Emergency, by Bee S. Hoiles. *Pub. Health Nurse*. Feb., 1928.

Social Hygiene Workers Believe in Education—"How much of the budget ought to go into educational measures? In the association budget for the last two years it has been about three-eighths. Anything up to 100 per cent was the consensus of opinion."—*Social Hygiene News* (Jan. 30, 1928) reporting some of the practical questions discussed at the annual meeting of the American Social Hygiene Association.

Health Propaganda in France—"With the assistance of the voluntary national health organizations a general propaganda committee was formed" by the Office National d'Hygiene Sociale. "This committee has endeavoured to organize a vast campaign of popular education throughout the country, through the press, posters, pamphlets, tracts, wireless talks, films, lectures, etc. It has also been active among large bodies of workers such as railway employees, the merchant marine and present and future teachers. In 28 departments it has carried on intensive campaigns in the form of Health Weeks and Health Fortnights, has supported health organizations and in a general way has contributed to the development of public health services or associations.

"One point which deserves special mention is the organization during the past year of a nation-wide propaganda campaign against venereal diseases, the results of which have been most satisfactory. . . . The Office has completely fused the various activities in the field of health education, which have hitherto lacked unity. Thanks to universal propaganda and to concentration on certain activities, the General Propaganda Committee has succeeded in awakening

a health intelligence among the public, thus advancing the cause of public health."—*World's Health*, 2 Avenue Velasquez, Paris, France, Jan., 1928. With reproductions of six French health posters strikingly different from any produced west of the Atlantic.

Why Do They Get Diphtheria in Detroit?—As is true everywhere because they lacked protection. In an attempt to learn why they were not protected the Detroit Department of Health

... made a study of 100 recent cases of diphtheria, the results of which are given below. Inasmuch as practically all the cases were among children, the question, as to why toxin-antitoxin had not been given, was answered by the parents.

In 45 cases toxin-antitoxin had not been given because of plain neglect—putting it off—on the part of the parents. In 14 instances parents had never heard of toxin-antitoxin. In 9 instances the parents did not believe in toxin-antitoxin. In 9 cases parents stated that the child had never been ill and that they thought it was not necessary to give toxin-antitoxin to a child who had never been ill. In 9 cases either the parent or the child was afraid that the giving of toxin-antitoxin might cause a little pain, that is, that it would hurt. In 6 instances the mother said that she did not have the time nor facilities for taking her children to a physician or clinic. In 3 cases the parent did not think it was necessary to have a child of preschool age protected against diphtheria.

There were the reasons given in 95 per cent of the cases studied. The remaining 5 did not have toxin-antitoxin because the child had been sick a great deal and the parents were afraid to have toxin-antitoxin given; the parents did not believe that toxin-antitoxin and vaccination against smallpox should be given in the same year, and as the child had just been vaccinated they were waiting until the following year to give diphtheria immunization; and because another child in the family had had a severe reaction and the mother was therefore unwilling to have the second child immunized.

Here are real ideas for the Detroit health workers to meet in their educational publicity. Would not such a study be worth while in other communities?

STATISTICS

Bar charts versus circle diagrams is discussed in the *Journal* of the American Statistical Association (Columbia University, New York, N. Y.) in the issues of June, 1926; March, 1927; and Dec., 1927. The last is devoted solely to "accuracy of judgment," disregarding "popularity and appeal," and other points. The conclusions do not seem to be sufficiently convincing to be quoted.

The not altogether convincing estimates of the economic waste through deaths by tuberculosis are improved on in *Health-grams*, Illinois Dept. of Public Health. Feb. 15, 1928. *Free*.

Snap, zip, vigor or kick may get into a diagram of statistical data after reading "Add a Picture to Your Sales Curve," by E. P. Hermann. *The Poster*, 307 South Green St., Chicago, Ill., Oct., 1927. 22 illus. 30 cents. (If it does not "take" with you, mail the copy you buy to the editor and he will buy it from you and refund the 30 cents.) *We wish to exhibit specimens of picture diagrams or diagrams with pictures at Chicago in 1928.*

RADIO

A series of radio talks has been given during the past two months by Dr. George K. Pratt and other members of the National Committee on Mental Hygiene staff on the subject of "Why Men Fail," from Station WEA. The talks were based upon a series of articles under this general title which appeared in the *New York Herald Tribune* and twenty other newspapers.

What does this mean? The opening paragraph of a radio talk: "It is the general opinion of scientists that cancer is at first a local disease. Something goes wrong with the regulating mechanism of the body and as a result the unwholesome persistent growth begins and once begun it cannot stop itself, but must be removed or destroyed." *Will someone re-write this for the radio audience?*

MOTION PICTURES

The Connecticut State Department of Health now offers 43 health films "covering almost every phase of health. These include science films all of which are valuable for use in the upper grades and in high schools, there are many popular films suitable for showing in public moving picture houses, some of which can compete easily with the best in the 'movies.'"—List *free*.

Pictures on child welfare, general hygiene, tuberculosis, malaria and sex education are supplied by the League of Red Cross Societies, 2 Avenue Velasquez, Paris, France. Catalogue *free*.

The series of motion pictures being produced for the American College of surgeons by the Eastman Kodak Co. are outlined in *The Motion Picture*, 469 Fifth Ave., New York, N. Y. No. 10. *Free*.

"Teaching with Motion Pictures in Nursing Schools and Hospitals," by Priscilla Bernard. *Trained Nurse*, 468 Fourth Ave., New York, N. Y. Oct., 1927. 35 cents.

LISTS

"Directory of State and Insular Health Officers, 1927." *Public Health Reports*, U. S. Public Health Service. Nov. 11, 1927. 5 cents, from Superintendent of Documents, Washington. Includes main budget items, and publications issued.

EXHIBITS

Small cut-out photographs, 6, 8 or 10 inches high, have been effective for window display or exhibit use. In Toledo the Community Chest placed groups of 8 inch figures in an open-front box or theatre 16 by 26 inches, and 6 inches deep. By having the mounting and cutting done by the children of one of the member agencies the cost was but a few cents for each figure.

"A Museum Illustrating Welfare Work for Cripples in Germany," by Dr.

Hellmut Eckhardt. *World's Health*, Nov., 1927.

"What a Health Department Could Do for Suffolk County" was graphically sketched in attractive colors at the Suffolk County (N. Y.) Fair on a map 3 by 6 feet. Reproduced in *S. C. A. A. News*, 105 East 22d St., New York, N. Y., Oct., 1927. *Free*. They hid the modest 20-cents per capita in small letters in a corner! Why not at the top: "for only 20 cents per capita," or "What Two Dimes Apiece Would Do for Suffolk County Citizens."

HONORABLE MENTION

International Health Board: for an illustrated, readable, comprehensive, condensed annual report, with table of contents and index (the latter, unfortunately, with legibility lessened by the use of capital letters).

PUBLIC SPEAKING

Audiences totaling 250,000 were reached in 1927 by 1,125 lectures given through the American Social Hygiene Association.

Whom Shall we Have as Speaker? Council of Social Agencies, 312 West 9th St., Cincinnati. 30 pages. 4 cents for postage. Suggestive where health and social agencies are planning a common speakers' service. Health topics are grouped as "general" on group and community health problems and needs, and "instructive" on how to preserve health and prevent disease. Then there are talks on child health and mental hygiene.

POPULAR HEALTH ARTICLES

"Food, the New Medicine," by E. R. Stevenson. *High School Service*, American National Red Cross, Washington. Dec., 1927. 15 cents. Vitamins simplified.

"For Longer and Healthier Lives." *Literary Digest*. Jan. 28, 1928.

"How's Your Cold?" by Ruth F. Wadsworth, M.D., *Collier's*, New York,

N. Y. Jan. 28, 1928. "The prevalence of the common cold is an indictment of our civilization." Good popular booklet copy. Read to see how the subject *can* be made readable.

among the reviews in *World's Health*, 2 Avenue Velasquez, Paris, France, seems too small. Scientific and popular books, reports of demonstrations, and reports of special studies would be welcomed by the editor.

OFFICE

Many hints, helps and hunches on office practice are to be found in "Over My Desk," a monthly page conducted by Elwood Street in *The Survey*.

Minor distinction through postage stamps: In place of a one and a half cent stamp use three half cent stamps; again place the three stamps end for end instead of side by side; watch for the special commemorative stamps sold from time to time—sometimes one must send to one of a few post offices to which the sale is limited.

"The magazines (received at national headquarters of the American Red Cross) will be routed to anyone wishing to see them regularly." Are the professional periodicals and other helpful publications routed to all members of our staff who might be interested? Have we ever sent to all staff members a list of the periodicals received regularly? Do we list periodicals received in a department or by an individual staff member who would be willing to loan them to others?

"Personal" on letters may be unfortunate if not used with discretion. A Philadelphia publishing house is unwise enough to add "personal" to the address on envelopes containing book circulars.

OPPORTUNITIES

Five posters were reproduced in *The Poster*, 307 South Green St., Chicago, Ill. Nov., 1927, from a heart poster contest conducted by the Tuberculosis Society of Detroit, Mich. *The Poster* editor will welcome advance information and photographs of the prize winners from other competitions.

* The proportion of public health books from the United States and Canada

REGRETTABLE

That the interesting health reading in the *Monthly Bulletin* (Galveston) is always *after* the uninteresting though significant statistical material which is given the choice first pages in every issue.

That one city health department has been written 3 times (without results) suggesting that the street number be added to the address of the monthly bulletin sent to a reader in New York City. Every month, without the street address, the bulletin must be passed on to a post office worker who looks up that street address.

AWARDS

Awards for good publicity will be made by the Committee on Publicity Methods at Memphis, May 2, 1928. The conditions for entering examples in Newspaper Publicity, Letters, Folders and Booklets are supplied by the Committee at 130 East 22d Street, New York, N. Y. Material issued since March, 1927, may be entered.

Somewhat similar awards may be made by the Public Health Education Section of the A. P. H. A. at Chicago in October, 1928.

The awards in both groups of contests will be made for specific good features: for the lead of an article, for the cover of a report, etc.

TITLES

"Conquerable—But Unconquered."—*Weekly Health Review*, Racine. Diphtheria.

"Where Do You Suppose I Could Have Caught It?"—*Weekly Health Review*, Racine.

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

Surgeon General Cumming Reappointed—Appointment of Dr. Hugh S. Cumming for his third term as Surgeon General of the U. S. Public Health Service was confirmed by the Senate on January 27, 1928. Dr. Cumming became Surgeon General in 1920, succeeding Dr. Rupert Blue.

Progress on the Parker Bill—At the hearings on H.R. 5766, the Parker Bill for coördination of federal health activities, held by the subcommittee of the House Committee on Interstate and Foreign Commerce on January 11 and 12, 1928, considerable opposition was expressed to the first and second sections of this measure. These important sections would empower the President to transfer executive bureaus doing health work to the U. S. Public Health Service by executive order, or direct that scientific personnel of the U. S. Public Health Service be detailed to other bureaus to assist or supervise public health activities. The opposition came from agricultural and dairy interests, who seem to feel that the U. S. Public Health Service already has too much power and would get too much more by the passage of such a law. A new bill, H.R. 11026, has been introduced in place of H.R. 5766 and this new one, with the former first section deleted, was reported to the House on February 21, 1928.

While the remainder of this bill contains many important matters, the first two sections were the ones which would really bring about the necessary correlation of federal health work, which sanitarians have been urging for half a century or more.

Milk Import Act in Force—Funds made available by the First Deficiency Act, signed by the President on December 22, 1927, have made possible the enforcement of the Federal Import Milk Act, which became a law on May 15, 1927. The Food, Drug and Insecticide Administration of the Department of Agriculture has organized a staff and arranged to issue the permanent permits required. Since the passage of this law, milk and cream have been coming into the United States under more than 3,800 temporary permits. The Canadian authorities are coöperating by conducting tuberculin tests and making sanitary inspections of dairies in the Dominion. Our government has placed an inspection service at Rouses Point in New York and will establish other stations.

An investigation into the costs of production of milk and cream was ordered by the U. S. Tariff Commission on March 4, 1926, and hearings were scheduled for this purpose, beginning February 23, 1928.

An appropriation of \$10,000 for expenses of an American delegation of ten to attend the Eighth International Dairy Congress in London next July was voted in the House on January 26, 1928, and in the Senate on February 21.

Amendments to the Sanitary Code of New York with reference to milk are given in *Health News* of that state for January 2, 1928.

Federal Subsidies for Rural Health—A million dollars a year from the national treasury for rural hygiene—This is the object of a bill, H.R. 7005, introduced in Congress by Representative Bankhead of Alabama, and referred

to the Committee on Interstate and Foreign Commerce. This same measure, which is similar in principle to the so-called Sheppard-Towner Law, has been before the last two or three Congresses, but so far without action. The U. S. Public Health Service is designated as the executive agency to administer the act and to approve state plans for rural hygiene. Federal grants would be made only to those states accepting the act and matching the federal money with a state appropriation.

An Emergency Fund—Another million would be appropriated by the national government as an emergency fund to cope with unusual perils to the public health, according to S. 2691, introduced in the Senate by Dr. Cope-land. This bill recites that it shall be the duty of the Surgeon General to present to the President any situation where there is great and imminent peril to the public health by reason of impending pestilence, and if the President is convinced of its existence, the Surgeon General would be directed to take such measures and incur such expenditures, in coöperation with state health authorities, as might be necessary.

To Make May Day Official—May Day would be officially designated as national child health day by a joint resolution, H.J. Res. 184, entered in the House by Representative Greenwood of Indiana, and in the Senate by Mr. Barkley as S.J. Res. 89.

Other Bills Before Congress—Hearings on a bill to grant \$50,000 toward the maintenance of the Gorgas Memorial Institute in Panama were held on January 20, 1928, before the Judiciary Committee of the House. A resolution (H.J. Res. 175) has been introduced to change the name of the Ancon Hospital in the Canal Zone to the General Gorgas Hospital and this was

referred to the Committee on Military Affairs of the House. An appropriation of \$310,000 for construction at Walter Reed Hospital in the District of Columbia is provided by H.R. 9676, passed by the House on January 26. The measure (H.R. 5658) to allow the rank and pay of a colonel in the Medical Corps of the Army came up in the House on January 16, 1928, but was passed over on objection by Mr. Blanton. A bill (H.R. 10078) to strengthen the immigration laws provides for deportation of aliens who violate the white slave and narcotic laws. There are several bills for a federal department of education (H.R. 7, H.R. 5693, H.R. 5790, S.1584). The Department of Agriculture would be enriched and probably enlivened by a Federal Alcoholic Liquor Board, according to H.R. 8131. There are a number of bills to regulate chiropractic, osteopathy, and other cults in the District of Columbia.

The Message of Governor Smith—More than half of the famous 100-page message transmitted by Governor Alfred E. Smith to the Legislature of New York on January 4, 1928 is concerned with public welfare. Health comes in for a fair share of comment, for, says Governor Smith, "Proper attention to the preservation of the public health will produce a strong, healthy, vigorous people. There is no greater state asset." He then goes on to say that there is abundant reason to be well pleased with progress in this field in New York during the past ten years, and he proceeds to outline some of the activities of the Department of Health.

With respect to the Federal Maternity and Infancy Law, the Governor says, "Although upon questions of political principle there existed considerable opposition to the state taking advantage of the federal government offer of funds under the Maternity and Infancy Aid

Act, the state adopted a wise course and allowed the political debate to be carried on in its proper place, but meanwhile made provision to meet the contributions of the federal government for maternity and infancy care."

After discussing the Physically Handicapped Children's Law, by which judges of the Children's Court are authorized to issue orders covering the physical care and treatment and the education of physically handicapped children, the Governor devotes some attention to public health nursing. "One of the most important factors in health work is the public health nurse," he says, pointing out that there has been an increase from 500 such nurses in the state ten years ago to 1200 today.

The importance of the county health law, which was passed in 1921, is stressed in the message: "Our knowledge of preventive medicine has reached the point where for best results its administration should be in the hands of a qualified full-time expert in this field." Although towns and villages can seldom afford such service, only one county has taken advantage of it, and the Governor rightfully believes that New York is laggard in this respect.

Much attention is devoted in the message to the Mental Hygiene Department. There is also considerable discussion of the workmen's compensation law, in connection with which it is pointed out that provision has been made for compensation for 23 distinct forms of occupational diseases.

Among the 29 recommendations, are several affecting public health. These include suggestions for extension of the Physically Handicapped Children's Law to cover physical handicaps other than orthopedic defects; establishment of a minimum wage board to study the problem of wages paid to women; provision for compensation for all occupational diseases arising out of and in the course

of employment; and increased facilities for after-care.

From the standpoint of public health, this document from the pen of Governor Smith has all the marks of statesmanship.

State Health Laws in 1926— Approximately 110 new laws and 60 regulations pertaining to public health were passed and adopted during 1926, according to William Fowler, LL.B., whose latest compilation of *State Health Laws* has just been issued by the U. S. Public Health Service as *Supplement No. 65*. Mr. Fowler has listed for us some of the subjects treated by these new laws. Tuberculosis hospitals, water and sewage, and health authorities seem to have been the favorite health legislative topics during 1926, while shellfish control, camp sanitation, and communicable disease control induced most of the new regulations. Unlike some years in the past, there was very little on the venereal diseases in 1926, though two states, Connecticut and Illinois, adopted regulations on this subject. An interesting law was one passed in Louisiana placing a tax on kerosene to raise funds for various public health purposes. Only one state, Rhode Island, had a new law dealing with milk, though four states adopted regulations concerning this product. A law relative to cancer, providing for a state program, was passed in Massachusetts. These annual compilations of state health laws have been issued since 1911 by the U. S. Public Health Service and are useful bulletins, especially for sanitarians interested in the laws of states other than their own.

Proposal to License Health Officers—Examinations and licenses for health officers are now required by law in only one state, New Jersey, though this method of attempting to secure well qualified health officials has been much

discussed by sanitarians during the past few years. Recently there has been introduced in the Massachusetts Legislature a bill to provide for the licensing of local health officers. This measure has been carefully drafted and is a good example of a concise, yet complete, bill and one which contains a proper delegation of authority. This bill is, in fact, so important that it is herewith presented in full.

Section 1. On and after one year from the date of passage of this act no person shall be appointed as a local health officer, or as an executive or agent of the board of health of any town or city having a population of more than ten thousand or as the executive officer or agent of any group of towns having a combined population of more than ten thousand unless he has been licensed as a health officer by the State Department of Public Health.

Section 2. A license as a health officer shall be issued by the State Department of Public Health to each person who passes an examination in the following subjects: communicable disease control, epidemiology, public health laboratory methods, personal hygiene, municipal sanitation, water supply and waste disposal, control of milk and other food supplies, vital statistics, and sanitary law.

Section 3. The State Commissioner of Public Health shall appoint a board of not more than five well qualified persons to act as examiners of applicants for licenses as health officers. Such examinations shall be held at such times and in such places as the Commissioner shall determine. Such examinations shall be conducted in accordance with rules made by the State Department of Public Health.

Section 4. This act shall not prevent any local board of health from continuing in office, without examination and license, any health officer or agent who fills such office at the time of passage of this act.

Section 5. A fee of . . . shall be paid to the State Department of Public Health by the applicant for each examination taken for a license as health officer.

Health and Mental Responsibility
—Attempts to set up mental irresponsibility as an excuse for all behavior not in accordance with accepted standards were strongly decried in a radio talk recently delivered by Dr. Frederick W. Parsons, Commissioner of the Depart-

ment of Mental Hygiene of New York. Some of these unscrupulous attempts were characterized as disgraceful by Dr. Parsons, who also stated that such methods caused public suspicion of the integrity of the medical and legal professions. It is, of course, proper that persons who are actually sick mentally and who do not understand the nature of the acts should not be held responsible for crimes and should be placed in suitable institutions, but attempts to secure their freedom because of alleged "brainstorms," "twilight states," and "emotional insanities," are "insults to group intelligence," according to Dr. Parsons.

Along these lines, it is interesting to note that a bill (H.R. 177) has been introduced in Congress for a laboratory in the U. S. Public Health Service to study the abnormal classes. Bills have also been introduced (S.2684, H.R. 9762) to regulate the commitment to and discharge from St. Elizabeths, the Government Hospital for the Insane, of persons certified by heads of departments. On January 13, 1928, St. Elizabeths and its superintendent underwent an attack by Representative Blanton. An appropriation for this institution was, however, adopted by the House.

Patents and Public Health—Several items of patent law having some effect on public health have recently been decided in the federal courts and the Patent Office. Thus, patents have been granted for a milk bottle having a neck with internal ribs and without the usual annular flange (Patent No. 1654365); and for an improvement on a process of obtaining "vitamins" (No. 1649520). A patent for a laxative chewing gum containing phenolphthalein has been held invalid by the Circuit Court of Appeals of the Second Circuit in *Health Products Corp. v. Ex-Lax Mfg. Co.*, because there was no disclosure of the actual commercial practice.

The most important of these decisions on patents has to do with an invention made by a chemist of the U. S. Public Health Service while he was in the government employ. The United States was held to be the equitable owner and entitled to assignment of this patent, in the case of *Houghton v. United States*, decided recently by the Circuit Court of Appeals for the Fourth Circuit. While on government duty Houghton conducted experiments on fumigants and developed an improved type which combined a warning or irritant gas with hydrocyanic acid gas. Contrary to the wishes of his employer, the U. S. Public Health Service, he obtained a patent, which was, however, disallowed by the Federal District Court of Maryland after the United States had brought suit. On January 10, 1928, this decision was upheld on appeal to the Circuit Court.

Miscellaneous—An osteopath cannot be appointed as a school medical inspector in New Jersey, according to a decision of the State Education Com-

mission, reported in the *New York Herald Tribune* for January 27, 1928.

Changes and additions to workmen's compensation laws in the states made during 1927 are outlined in the *Monthly Labor Review* of the U. S. Bureau of Labor Statistics for January, 1928.

Death due to actinomycosis has been held to come under the workmen's compensation law of Wisconsin in *Pfister and Vogel Leather Co. v. Industrial Commission*, 215 N. W. 815.

An exhibit for the International Exposition at Seville, Spain, to be held next October, is being prepared by the U. S. Public Health Service.

The U. S. Women's Bureau has issued a pamphlet (*Folder 5*) describing its activities. This bureau has prepared 4 bulletins on health problems of women.

The appendix of the *Congressional Record* for January 18, 1928, is embellished with a rather extensive article on the peril of narcotic drugs, by Richmond P. Hobson. It was placed there at the request of the Hon. Hugo L. Black of Alabama.

BOOKS AND REPORTS

Dictionary of Bacteriological Equivalents, *French-English, German-English, Italian-English, Spanish-English*—By William Partridge, F. I. C., Baltimore: Williams & Wilkins, 1927. 141 pp. Price, \$4.00.

The author has produced a book which may have certain uses, is well printed and very free from errors.

While the majority of the words included are used in bacteriology, there are many which do not belong to that science especially, and many more which the veriest tyro in science would understand without having to look them up in a special book. Others which need definition are omitted. Why, for instance, is the French word for otitis, the meaning of which is evident to everybody, given, while the word for mumps, which only those familiar with French know, left out? Surely mumps is discussed in bacteriological works as well as otitis. Many similar examples could be cited. There are numerous chemical and medical terms which are more used in ordinary medicine than in bacteriology. The definition for the word "témoin" is given as "control experiment," though it is applied to animals as often as to other control work.

It seems a waste of space to give the English equivalents of such words as camera lucida, carbonate, colon, eczema, ether, fungus, menthol, mucus, nickel, nitrate, peptone, pepsine, quinine, virus, and many others which are the same in English, and which any first course medical student would understand.

It would be more useful to give the equivalents in the different languages for the same set of words. In the book before us there are 2400 French, 2600 German, 1200 Italian and 1600 Spanish

words. French and German are more read than Italian and Spanish, but, by the same token, are more familiar and need less explanation.

M. P. RAVENEL

Diseases of the Mouth—By Sterling V. Mead, D.D.S. 274 ill. and 29 col. pl. St. Louis: Mosby, 1927. Price \$10.00.

We have with approval repeatedly called attention to the growing recognition of the importance of oral hygiene as a matter of public health. Only recently a well written book has classed it among the three great advances made within the last ten or fifteen years. With this we are inclined to agree. Consequently we always receive a book on oral hygiene with more than ordinary pleasure, especially if, like the present one, it is good. We believe that physicians generally are too much inclined to regard dentistry as a specialty, in which they have no concern, and to neglect the hygiene of the mouth, which is only incidentally connected with dental work, and which has a much wider bearing than the actual filling of teeth, or the correction of dental deformities.

The present volume is designed primarily for students. It begins very properly with methods of examination of the mouth and with certain general principles involved in diagnosis, which are of as much value to the average physician as they are to the dentist who does the practical work.

Living in Washington, as the author does, he has had exceptional advantages in ability to consult with prominent men in some of our services, as well as access to the Surgeon's Library, which is generally considered the best medical library

in our country, and one of the best in the world.

The author goes much further than average writers on oral hygiene. Not only does he consider the malformations and diseases which concern the teeth, the alveolar structures, the gums, the tongue, lips, related glands and accessory sinuses, but goes into such conditions as syphilis, diseases of the blood and blood vessels, nerves, etc. One chapter is devoted to the relation of oral sepsis to systematic disturbances concerning which the physician of today is so painfully aware, and about which we are all so eagerly seeking information.

We think the author has made a mistake in substituting rather jaw-breaking scientific names for some well known terms. "Pyorrhea alveolaris" is given to us under the name of "suppurative periodontoclasia," and one discovers this only in the index.

The book is beautifully gotten up, and abundantly illustrated with 274 excellent illustrations, most of which are photographs, and 29 plates in colors, all of which are well done. It is printed on the heavy paper of which our American publishers seem to be so unfortunately fond. On this account, the reading of the book is a burden, and one could very well knock an ox down with it.

M. P. RAVENEL

Subject Matter in Health Education—By *Ruth Strang, Ph.D.* *Contributions to Education, No. 222.* New York: Bureau of Publications, Teachers College, Columbia University. 1926. 108 pp. Price, \$1.50.

This book presents the results of a statistical investigation of health education in the United States as recorded in representative courses of study of 11 cities, 3 rural communities, 4 states, and in 14 selected texts. Some 43 of the 108 pages in the book are devoted to tables. Following these an evaluation is made of the usefulness

and scientific accuracy of the material review.

The author finds that numerous of the statements which occur commonly in courses of study and texts must be classed as of the undesirable type: because they are indefinite, (Drink plenty of water); they are of minor value to health (Keep the school room tidy); they are of the negative type (Don't bite your nails); they tend to bring out the reverse of what is desired (Stand straight, Keep your ears clean and free from wax); they are too sweeping and make no allowance for individual differences (Play hard and fair). Statements which are scientifically unsound likewise abound. Some of these are merely mild inaccuracies which state dogmatically as a fact points which have never been scientifically proved and on which there is a difference of opinion (A mid-morning lunch is very beneficial to children; Coarse foods are necessary for health); others are exaggerations (Cooked cereals make children strong and healthy); and still others are definitely inaccurate, (An apple a day keeps the doctor away. Protein causes an expenditure of more energy than it supplies). Attention is likewise called to the omissions in the texts of important types of material, and to the frequent faulty organization.

Having pointed out the shortcomings of the outlines and texts reviewed, the author very properly presents constructive suggestions gained from this material and from her own experience for the improvement of practices in the schoolroom. She outlines a method of organizing the subject matter of health education around health situations as they actually occur in the schoolroom, on the street, in the home. In conclusion the author includes sample pages of the Gates Strang Health Knowledge test which was one of the outgrowths of this investigation.

As a whole the book will be of interest

to directors of health education and others concerned in outlining courses of study, while the practical suggestions in the latter half will also be useful to the individual teacher. The study reveals a need for better courses of study outlined by specialists who can assure the accuracy of the material; outline it clearly, and logically; decide wisely on the grade placement of the various topics; and present the essential subject matter in sufficient detail to make it usable by the average teacher. LYDIA J. ROBERTS

**The Normal Diet, A Simple Statement of the Fundamental Principles of Diet for the Mutual Use of Physicians and Patients—By W. D. San-
sum, M.S., M.D. (2nd ed.) St. Louis:
Mosby, 1927. 136 pp. Price, \$1.50.**

The author has produced a book of much value, which can be read with advantage by the average person. Like the first edition, it contains some statements which are contrary to those made by standard physiological authorities, but these for the most part, concern minor matters.

A number of excellent menus are given, and we find in an appendix a number of weight and height tables taken from various sources. These are useful, if we remember the various criticisms which have been made of such tables, and do not depend too entirely upon them.

The printing and make-up of the book are excellent. M. P. RAVENEL

**Practical Pedodontia Or Juvenile Operative Dentistry and Public Health Dentistry—By Floyd Eddy
Hogeboom, D.D.S., (2nd ed.) St. Louis:
Mosby. 1927. 108 pp. Price, \$3.50.**

This attractively and fully illustrated book gives to the dental practitioner a clear statement of the objectives and methods in the practice of children's dentistry. The chapters present: the embryological development of the head

of the child, cavity preparation for deciduous teeth, filling material used in deciduous teeth, the treatment of the first permanent molar, the treatment of pulps in deciduous teeth, the problem of nutrition related to the teeth, prosthetic appliances, dental prophylaxis, and public health dentistry. All of these phases of the subject carry full illustrations. It is a book for the dental practitioner not for the sanitarian or layman. In his chapter on Public Health and Dentistry the author presents a discussion of the dental phase of the school health program using the work in Pasadena and Los Angeles as illustrations.

C. E. TURNER

**Secrets of Good Health—By Sir W.
Arbuthnot Lane, Bart., C. B. New York:
Doubleday, Page, 1927. 152 pp. Price,
\$2.00.**

This book is hard to evaluate. Much of it is written by the surgeon whose name appears as the author. Three themes predominate. The first boosts the New Health Society, of which Hippocrates is spoken of as the "greatest pioneer," and which is described as the "greatest movement of the age." The second idea concerns constipation, and the third dwells on the baneful effects of white bread, to the eating of which the author ascribes pretty nearly every trouble to which man is heir, up to and including cancer. This part of the book is written in superlatives. We are advised "On no account eat any white bread... the curse of our age is that we are provided with white bread." We are told "that a perfect dietary renders disease impossible," and are warned of the "terrible influence of diet and habit in the production of cancer." We are even told that in schools, time which should be spent in the toilet is "sacrificed to being present at Divine service." There is some very queer bacteriology and even more queer physiology. Some of the chapters written by others are

more conservative, but practically all show the influence of the "New Health Society" which is to bring about such a change in the world if only it can have its way.

The book is made up largely of articles contributed to the *Daily Mail* by the author, and others at his invitation. According to his own estimate "millions of people" have learned good habits and "thousands of letters" have been received showing the "incalculable value" of the teaching which has been given to them.

The book contains a considerable amount of good advice, but on the whole, is the expression of a fad in which there is some substance covered by a large amount of froth. M. P. RAVENEL

Hygiene and Sanitation for Nurses
—By George M. Price, M.D., (5th ed.)
Philadelphia: Lea & Febiger, 1927. 286 pp. Price \$2.25.

This book is divided into 7 chapters, which deal in turn with discussions of mortality problems and the rôle of the nurse; the hygiene of habitations, of foods, of childhood, of occupations; with infectious diseases and their prevention, and with constitutional diseases and personal hygiene. As a practical guide for nurses to modern hygiene and sanitation methods, this book has both good and weak features. It is unfortunate that a 1927 edition should devote a section to chemical means of water purification without mention of chlorination; or should give as an "official" definition of pasteurization "the heating of milk to a degree of heat sufficient to kill all most active germs," without an adequate presentation of modern knowledge regarding the value and increasing use of this method of safeguarding milk supplies. Four pages are devoted to gaseous disinfectants and to methods of disinfection of rooms, a practice discontinued by most modern health departments (except for destruction of insects), as contrasted

with only brief references to methods of immunization of children against diphtheria. The statement that "the Schick test in children has been used successfully by the New York Health Department in other diseases such as poliomyelitis, scarlet fever, measles, etc.," may be somewhat misleading.

The chapters dealing with the hygiene of habitations, and of occupations, are perhaps the most valuable portion of the book for nurses. With the exception of the discussion of milk, the chapter on foods and food supply may also be helpful.

IRA V. HISCOCK

Common Sense Health—By Arthur Geiringer, M.D. New York: F. S. Crofts & Co., 1927. 208 pp. Price, \$2.00.

This book comes to us with the approval of the Life Underwriters Association of Canada. It is very well written in popular language, and for the most part contains good advice which the average reader can follow with advantage. A number of statements arranged somewhat in tabular form give useful summaries of what has been discussed, and serve as concise reminders to the reader of what he should bear in mind. One of these is a series of questions which people should ask themselves in order to determine the general condition of their health.

Special prominence is given to oral hygiene, which the writer considers one of the greatest contributions made to preventive medicine during the last ten years.

Unfortunately there are some evidences of carelessness. The writer seems to regard vaccines and serums as identical, and his statistics concerning the Spanish-American and the World Wars are woefully inaccurate. During the latter, he says that there were only 297 cases of typhoid fever in the entire American Army of over a million men. The fact is that there were 1,897 cases, with 287 deaths, and the number of men

concerned was 4,128,478. We must also disagree with the advice to spray the nose with albolene containing camphor twice a day, especially during the winter months. Specialists say this is injurious, and one very prominent man in this line of work makes the distinct statement that the constant use of oils causes dryness of the mucous membrane of the nose and throat.

With these exceptions the book can be recommended. It is well printed on light paper with a mat surface.

M. P. RAVENEL

A Handbook of Summer Camps—
(4th ed.) Boston: Porter Sargent, 1927.
872 pp.

This is the fourth edition of an annual survey of summer camps for boys and girls from coast to coast. Coeducational camps, camps conducted by religious denominations, and national organizations, camps with school connections and those emphasizing arts and crafts, dramatics, dancing, nature study, foreign language study, and physical educational courses are included in the list. The camps are also listed geographically and the names of directors and endorsing groups are given. The introduction carries a history of summer camps with special contributions by camp directors. The maps and index add to the value of the book, which has been compiled with care and thoroughness.

Diphtheria Immunization in Schools—Monograph No. 2 published and distributed by the School Health Bureau of the Welfare Division, Metropolitan Life Insurance Co. 22 pp.

This monograph makes suggestions for a workable program, showing how school executives can secure the coöperation of the teachers, parents and children in the diphtheria immunization campaign. It has been prepared by a committee consisting of Prof. C. E. Turner, Massachusetts Institute of Technology, Dr. Peter Sandford, University

of Toronto, and Dr. Florence Brown Sherbon, University of Kansas. The detailed work in the preparation of the study was done by C. Margaret Munson, a special student in the Department of Biology and Public Health, Massachusetts Institute of Technology. A. B. T.

America's Human Wealth—The Money Value of Human Life—
By Edward A. Woods and Clarence B. Metzger. New York: F. S. Crofts & Co., 1927. 193 pp. Price, \$2.00.

Three of the five chapters, about one-half of the book, are devoted to an introduction and to the history of money valuations of human life from the earliest times to the present. In Chapter Three, the title of which is "Modern Estimates of Human Life Values," the authors make no mention of the reviewer, or the most significant modern work in this field, that of Dr. Louis I. Dublin. They do worse than ignore Dr. Dublin's widely known contribution by mentioning an old estimate of his made in connection with a study of the cost of tuberculosis—work long superseded by more recent researches.

In the judgment of the reviewer, a book which makes so serious an omission does not merit the confidence of the reader.

ROBERT E. CHADDOCK

The Oxygen Demand of Polluted Waters, U. S. Public Health Service Bull. No. 173 and Mortality Among Negroes in the United States, U. S. Public Health Service Bull. No. 174. Washington, D. C.: Federal Treasury Department. Free.

Bulletin No. 173 was prepared by Emery J. Theirault, chemist of the U. S. Public Health Service. The bulletin dealing with the Mortality Among Negroes in the United States was written by Mary Gover, Sc.D., assistant statistician of the U. S. Public Health Service with an introduction by Edgar Sydenstricker.

A. B. T.

The Preschool Service in a General Health Program—*Practical Procedures, in the Home, in Medical Conferences, and in Mother and Child Classes*—New York: East Harlem Nursing and Health Demonstration, 354 East 116th Street, New York, N. Y., September, 1927.

This is one of a series of reports on the work of the East Harlem Nursing and Health Demonstration. In a small highly congested area of New York City was organized five years ago an experiment in coöperation by the Henry Street Settlement, the Association for Improving the Condition of the Poor, the Maternity Center Association and the American Red Cross. This booklet covers in outline form with some discussion the procedures used in the home, in medical conferences and in mother and child classes.

The preschool service was so organized that all procedures may be generally classified under one of the three headings of home visits, physician conferences in the center with both nurse and nutrition workers present, and classes of groups of mothers and children. The education of the mother is no doubt the principle around which the whole scheme is organized.

How to reach the 6,000 preschool age children of this community would seem to be a difficult problem but the introduction states:

The service grew rapidly. At only one time was any "canvassing" done to find children and this was soon discontinued as the problem early became one of selection from the large number of children who needed the service and who were known to the field workers.

The contacts were made:

- A. By transfer from the infant service
- B. Through the acute nursing service in families not previously known
- C. Referred by social agencies
- D. In families carried for other health services
- E. Through application to the clinic
- F. Referred by staff workers

Beyond this statement we are uncertain

as to how many of the 6,000 children were reached although the statistical summary gives the children and mothers attending the various forms of activity carried on without a definite statement as to whether the same child may have been counted more than once in the several services rendered.

This report not only tells in outline what kinds of procedures and policies were followed, but presents all the routines and principles followed in home visits, the medical conferences at the health center and the lesson plan of the 14 classes for mothers. The organization of the conferences, arrangement of appointments, the equipment, the duties of the staff, the posture class procedure, record forms, printed and mimeographed material used are all presented for the help and guidance of other workers contemplating a similar service. Illustrations of the health center equipment, the staff at work, and the display of posters and lesson leaflets for the mothers' classes gives added interest to this booklet. Suggested equipment with prices for children's playrooms and sources for obtaining materials for posters and exhibits are additional useful features.

With such a presentation of method interest is aroused at once as to evidence of accomplishment, and it is hoped that future publications from this demonstration may, through critical analysis of the activities, throw additional light upon the successes and possible failure that may be expected from such a program.

H. H. MITCHELL

Introduction of Sex Education Into Public Schools—By Thomas M. Balliet, LL.D. New York: American Social Hygiene Assn. 1927.

The title of this small pamphlet explains the contents which also include the administrative problems that arise in connection with this subject. A list of social hygiene publications is given.

A. B. T.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Epidemiological Report—League of Nations—The fourth epidemiological report of the Health Section of the League of Nations for the year 1926 occupies 100 pages and contains an immense amount of valuable information to health administrators. In previous reports, statistical tables have been arranged to show the conditions in each country separately, but now all information is grouped according to disease. This enables the reader to obtain a better view of the situation of any particular epidemic disease. A detailed tabular index has been prepared, and this makes unnecessary a large number of tables in the text. Carefully prepared maps and charts add interest to the report. The arrangement of these charts and statistical tables in relation to descriptive text is worthy of study by health workers preparing annual reports.

Information on the prevalence of notifiable diseases is now received by the Health Section from practically all countries in which such information is collected. It is amplified by mortality statistics, by cause, for large towns throughout the world. Plague was on the whole more prevalent in 1926 than in 1925. This increase, apparently temporary, occurred in many countries, but was most marked in northern India. The geographical distribution of cholera was similar to that of the previous year. There was observed comparative quiescence in main centers in India, marked extension in various countries further east, with complete absence of the disease west of India. The reappearance of yellow fever in Senegal in October, after the arrival of a convoy of 200 Syrians, gave rise to a series of cases in widely separated localities which had not been infected for many years.

According to this report, the classical type of smallpox has now become fairly rare in Europe, except in the Union of Soviet Socialist Republics, but mild smallpox continues to be spread in England. It seems from mortality reports that the severe form still predominates on the continent, at least in France, southern and eastern Europe. It is stated that the United States is in much the same position as England, in that the mild form has been spreading for a number of years. "Vaccination laws are insufficient in many states and the proportion of vaccinated children is, over large areas, below the safety limit." The situation of the United States is said to be less favorable than that of England because the disease began to spread earlier and is now of more or less common occurrence in practically the whole of the country, while in England, so far, only a limited area in the north is infected.

Typhus fever has decreased, and is now, so far as Europe is concerned, of practical importance only in eastern Europe, although endemic centers still exist in a few other localities. Undulant fever occurs in most Mediterranean countries, but is nowhere very prevalent except in Malta. Enteric fever is spread over the whole world in contrast with most of the diseases previously mentioned. Interesting data are given for different countries regarding the incidence of this disease. The most severe outbreak of typhoid fever in 1926 was at Hanover, Germany, which began toward the end of August and lasted throughout September. There were in all about 2,500 cases and 260 deaths in a population of approximately 425,000. The case mortality rate was 10.4 per cent. This epidemic was preceded by one

of probably between 20,000 and 30,000 cases of acute gastric and intestinal catarrh, which lasted until the end of August. According to conclusions of the government commission, the epidemic was probably due to water-borne infection.

The year 1926 passed without any influenza epidemics of primary importance. "Together with the two epidemic diseases of the central nervous system—epidemic encephalitis and epidemic poliomyelitis—this disease constitutes undoubtedly the most urgent unsolved epidemiological problem." Statistics regarding the incidence of poliomyelitis are not available for all countries. Acute poliomyelitis is stated to be far more prevalent in Europe, North America, New Zealand and Australia than elsewhere. A decrease was noted during the year in the United States and Canada.

The incidence of diphtheria in most countries has in recent years been running its normal course with small temporary increases and decreases. A more permanent improvement seems to have occurred in the death rate from diphtheria, but it has, on the whole, not been so great as in the case of scarlet fever. In the United States where the immunization campaign is more vigorously pursued than elsewhere, there has been a steady decrease of diphtheria since 1921. Measles undoubtedly causes more deaths throughout the world than either scarlet fever or diphtheria, being prevalent in both cold and hot climates and among most races. It probably causes more deaths in Egypt and the adjoining part of Asia than any other epidemic disease. Notification of whooping cough cases is not compulsory in many countries, and is incomplete in most countries. The reports are probably more complete in Denmark than elsewhere; in 1926 there were 890 cases per 100,000 inhabitants. It is an important disease which causes considerable mortality among the very small children

in most countries. In Mexico there were more deaths from whooping cough than from the other three epidemic diseases of childhood combined. It causes a greater mortality than either diphtheria, scarlet fever or measles in the Scandinavian countries, the Netherlands, Germany, Switzerland and Austria.

Hamilton, Ont.—Hamilton's progress in health work is effectively set forth in a report for each of the years ending October 31, 1926 and 1927. The form of the report is of interest. The pages are $8\frac{5}{8}$ inches x $11\frac{3}{8}$ inches. The first two pages give the organization and personnel of the board and the department, the third page carrying a classified financial statement arranged by functions. Photographs of city officials and bureau heads precede an interesting account of the medical officer of health. Effective graphs add to the clarity of the report. An alphabetical index facilitates reference to special topics.

Diphtheria immunization work is carried on in all the clinics, as it was found that a large number of children could be reached through these channels. This city with a population of 123,359 expended through the health department \$87,616 during the current year 1926. A birth rate of 22.5, a death rate of 10.46 and an infant mortality rate of 65 are recorded. It is noteworthy that these statistics with the principal causes of death are briefly mentioned in the early part of the report.

In the 1927 report, interesting charts and tables indicate the trend of diphtheria in this city since 1905. In that year, with a population of 57,561, there were 218 cases with 22 deaths. With considerably over twice that population in 1926 there were 121 cases with 3 deaths, while in 1927 there were only 11 cases with 1 death. "When the department commenced its diphtheria immunization work in 1922 we expected, perhaps, 5 years as the period to elapse

before any appreciable results could be noted. The figures for this year not only show a remarkable diminution in the number of cases and deaths, but far surpass our most sanguine hopes."

New Haven Community Center—How an annual report, with considerable statistical data, may be made interesting and attractive is demonstrated in the 94th report of the Children's Community Center. Effective photographs of children and buildings, with excellent graphs and charts, are distributed throughout. These are carefully arranged in relation to the descriptive text. A study of this report gives one a good picture of the year's work, with its special problems and accomplishments.

In this institution, with its modern buildings and equipment, medical care following a complete physical examination safeguards health; personality trends are studied; psychological examinations are used in educational and vocational guidance; and preparation is given for placement in carefully selected and supervised foster homes. The children are received from other agencies, parents or guardians, without regard to race, creed or color, and no effort is spared to provide them with scientific foster parenthood.

Montreal Anti-Tuberculosis and Health League—The third annual report of this organization contains annual meeting addresses and summaries of a year's work. The address of the chairman of the board of directors is of special interest because of proposals or suggestions made in regard to the work of different official health and school agencies for the improvement or expansion of their programs. The general health situation has been surveyed for this purpose and the recommendations seem in accord with modern tendencies.

From the managing director's report,

it is learned that over 6,000 copies of a booklet *Health in the Home* were distributed in homes under supervision. This manual is also used as a textbook for group instruction. The Royal Edward Institute received 1,300 copies, upon request, for their patients. Through the courtesy of the school commissions, a book-plate of health rules was given to each school child, and under the supervision of their teachers, was pasted in one of their school books. This is an educational device worthy of note. The report contains an excellent analysis of the various types of cases under supervision of the league.

Shreveport, La.—The biennial report of Shreveport for 1925 and 1926 covers the work of the different city departments, including health. Food inspections include all places where food or drink is prepared, served or sold. The U. S. Public Health Service standard milk ordinance has been adopted, and there is an active movement for the pasteurization of milk. All milk and dairy products used in the manufacture of ice cream are either boiled or pasteurized. There were 2,015 samples of ice cream analyzed with 735 plant inspections during the period.

Mosquito control work is said to date from 1923 following a dengue fever epidemic. By a gradual process of education and demonstration, interest has been aroused so that now there are provided systematic control measures practically the year round.

School medical examinations are carried on under the Board of Health. Of 15,591 white children examined, 7,592 were found to have defects, while 6,589 defects were corrected. Of 6,700 colored children examined, 3,109 were found to have defects, while 2,330 defects were corrected. Circulars and booklets on child health have been widely distributed.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Mosquito Larval Food—Mosquito larvae hatched from eggs freed from contaminants were fed upon pure cultures of various unicellular organisms. Yeast, infusoria, algae, and bacteria all proved to be suitable foods, but no considerable larval growth could be obtained on sterile nutrient media or dead organic material.

BARBER, M. A. The Food of Culicine Larvae. *Pub. Health Rep.*, 43:1 (Jan. 6), 1928.

An Obesity Clinic—An out-patient clinic for fat people was tried experimentally and found useful. The average weight loss of 183 patients was 15 lbs.

BAUMAN, LOUIS. Obesity. *J. A. M. A.*, 90:1 (Jan. 7), 1928.

Private Practice and Public Health—The story of the Fargo (N. D.) health demonstration reveals a method by which health officials may maintain the cordial interest and support of the local medical society. A little tact and even the lion and the lamb may lie down together.

CARPENTER, G. A., et al. The Local Medical Society and Public Health. *J. A. M. A.*, 90:3 (Jan. 21), 1928.

Some Mental Hygiene Problems—Tantrums, day dreaming, inferiority, escape from reality, and fixations are discussed and illustrated with some rather broad examples. Effective solutions for some of the difficulties are neglected.

CRONNIN, H. J., and SULLIVAN, E. A. The Problems of Adolescence. *New York J. Med.*, 28:2 (Jan. 15), 1928.

A Mechanical Respirator—This paper describes an apparatus resembling a huge autoclave into which the patient is placed. A large pump alternately raises and lowers the pressure causing an interchange of air in the lungs.

DRINKER, C. K. New Apparatus for Artificial Respiration: The Barospirator of Prof. T. Thumburg. *J. Indust. Hyg.*, 10:1 (Jan.), 1928.

Toxins of Tubercle Bacilli—Experimental evidence is reported which indicates that the tubercle bacillus produces a filterable toxin from which an antitoxin may be obtained in sheep. The toxin may be used as a reliable skin test.

EBERSON, F. Filterable Toxins of Tubercle Bacilli and Production of Antitoxic Serum in Sheep. *J. A. M. A.*, 90:4 (Jan. 28), 1928.

Vitamin E Deficiency Disease—Laboratory studies revealed in white rats the existence of a hitherto unreported disease of nurslings, developing in the young of mothers deprived of vitamin E.

EVANS, H. M., and BURR, G. O. Development of Paralysis in the Suckling Young of Mothers Deprived of Vitamin E. *J. Biol. Chem.*, 74:1 (Jan.), 1928.

Vitamin B During Lactation—Studies on white rats indicate that the increased amounts of vitamin B needed during lactation is due to the greater need of the anti-neuritic, not the growth-promoting factor of the vitamin B complex.

EVANS, H. M., and BURR, G. O. On the Amount of Vitamin B Required During Lactation. *J. Biol. Chem.*, 74:1 (Jan.), 1928.

Bacteriologic Control of Water—This paper reviews briefly some of the measures advocated for the bacteriologic examination of water supplies and considers the significance of the results.

HALL, I. C. The Practical Utility of Bacteriologic Control of Water Supplies. *J. Am. Water Works A.*, 19:1 (Jan.), 1928.

Water- and Milk-Borne Typhoid—The natural result of neglecting the protection by chlorination of the water supply and the pasteurization of milk

was visited upon Santa Ana, Calif. Public health administration would profit if more cities that sowed the wind might reap the whirlwind.

HALLIDAY, C. H., and BECK, M. D. Typhoid Fever Epidemic, Santa Ana, California. *J. Prev. Med.*, 2:1 (Jan.), 1928.

Measles in Child Caring Institutions—The measles fatality rate among young children in institutions is from seven to ten times the rate for the state. Although convalescent serum favorably influences the fatality rate if administered during the incubation period, its use proved disappointing in this experience.

GODFREY, E. S., Jr. Measles in Institutions for Children. *J. Prev. Med.*, 2:1 (Jan.), 1928.

Trichinosis from Undercooked Pork—Outbreaks of trichinosis in this country usually are due to the consumption of raw infested pork. These British cases emphasize the dangerous possibilities of undercooked pork.

HARDY, T. L. A Report on Two Cases of Trichinelliasis. *Lancet*, 2:27 (Dec. 31), 1927.

Industrial Health Service—How far shall industrial physicians go in offering medical and health service in the homes of employes, is the question raised in this paper. The answer seems to be: any illness that can be treated at the plant dispensary.

KNAPP, R. P. How Far Should Industry Go in Caring for Cases of Illness Not Due to Employment? *J. Indust. Hyg.*, 10:1 (Jan.), 1928.

Causes of Stillbirth—A careful study of the causes of death in five hundred stillbirths indicates that diseases of the placenta, syphilis, and malformation occur at about equal rates.

NATHAN, L. W., and DROLET, G. J. Recorded Causes in Five Hundred Stillbirths in New York City. *New York J. Med.*, 28:2 (Jan. 15), 1928.

Goiter in School Children—This paper is a summarization of the observations made in the numerous goiter

surveys by the Public Health Service and other agencies. Endemic goiter appears to be more common in some sections of the middle west than in the far western states.

OLESEN, R. Endemic Goiter among School Children. *Pub. Health Rep.*, 42:52 (Dec. 30), 1927.

Significance of B. coli Tests—A technical paper comparing a number of differential tests for the presence of *B. coli* in water. Eosine-methylene blue and ferric ammonium citrate agar are suggested as the most satisfactory confirmatory mediums.

LEWIS, I. M., and PITMAN, E. E. The Correlation between Differential Tests for Colon Bacteria and Sanitary Quality of the Water. *J. Am. Water Works A.*, 19:1 (Jan.), 1928.

Irradiation and Colds—The ten minute irradiation of children's bodies once a week resulted in reducing the frequency of colds. The other factors were controlled as nearly as possible.

MAUGHAN, G. H., and SMILLY, D. F. The Effect of General Irradiation with Ultra-Violet Light upon the Frequency of Colds. *J. Prev. Med.*, 2:1 (Jan.), 1928.

Potency of Diphtheria Toxin-Antitoxin—Commercial toxin-antitoxin failed to induce immunity in the usual dosage when administered to many hospital nurses in Chicago; therefore five weekly doses were administered. A comparison of four commercial mixtures indicated wide variations in potency.

RHOADS, P. S. Commercial Preparations of Diphtheria Toxin-Antitoxin. *J. A. M. A.*, 90:4 (Jan. 28), 1928.

Yellow Fever Transmission—Yellow fever was found to be transmissible to macacus monkeys by direct injection and through mosquitoes. Mosquitoes were found infective after sixteen days' incubation. The incubation period in the monkeys was from two to six days. No leptospiras could be found.

STOKES, A., et al. The Transmission of Yellow Fever to Macacus Rhesus. *J. A. M. A.*, 90:4 (Jan. 28), 1928.

Carbon Monoxide Safeguards—Laboratory and field studies indicate the failure of ozone generators to oxidize carbon monoxide, thus rendering it harmless. Open windows or mechanical ventilation are the suggested methods of removing the danger.

SALLS, C. M. The Ozone Fallacy in Garage Ventilation. *J. Indust. Hyg.*, 9:12 (Dec.), 1927.

Scarlet Fever Control—A detailed statement of the accepted facts about scarlet fever and control measures, prepared for popular distribution. Such statements about all the diseases should be made available for the use of health officials.

SCHERESCHESKY, J. W., and DYER, R. E. Scarlet Fever: Its Prevention and Control. *Pub. Health Rep.*, 43:2 (Jan. 13), 1928.

Tuberculosis Prevention—A plea for more consideration on the part of health officials of tuberculosis case finding and case supervision. The falling

death rate should be an incentive not for slacking but for more thorough and vigorous action.

SCRASE, F. E. Administrative Problems of Tuberculosis. *Pub. Health*, 41:4 (Jan.), 1928.

British Puerperal Fever Regulations—Any febrile condition occurring within three weeks of childbirth must be reported as puerperal fever. Proposals for lowering the puerperal death rate are given thorough consideration.

THOMSON, C. S. The Public Health (Notification of Puerperal Fever and Puerperal Pyrexia) Regulations 1926. *J. Stat. Med.*, 34:1 (Jan.), 1928.

Diphtheria Prophylaxis and Asthma—Prophylactic treatment with diphtheria toxin-antitoxin produced severe attacks of asthma in children found sensitive to horse serum.

WALDBLOTT, G. L. Diphtheria Prophylaxis Among Asthmatic Patients, *J. A. M. A.*, 90:4 (Jan. 28), 1928.

WHAT YOU SHOULD KNOW ABOUT HEALTH AND DISEASE. By Howard W. Haggard, M.D. New York: Harper, 1928. 538 pp. Price, \$5.00.

A TREATISE ON HYGIENE AND PUBLIC HEALTH. By B. N. Ghosh. (6th ed.) Calcutta: Scientific Publishing Co., 1927. 667 pp. Price, \$2.00.

PHYSIOLOGY AND HUMAN LIFE. By Robert A. Budington. Newark: Silver, Burdett & Co., 1927. 395 pp. Price, \$1.56.

A TEXTBOOK OF BACTERIOLOGY AND ITS APPLICATIONS. By Curtis M. Hilliard. Boston: Ginn, 1928. 329 pp. Price, \$2.80.

THE CHEMISTRY OF WATER AND SEWAGE TREATMENT. By Arthur M. Buswell. New York: Chemical Catalog Co., 1928. 362 pp. Price, \$7.00.

A MONOGRAPH COVERING THE ORIGIN, HISTORY AND SIGNIFICANCE OF THE TERM CASTILE SOAP. By Robert W. Mitchell, Ph.D. Cambridge: Author, 1927. 185 pp.

THE TEN COMMANDMENTS OF HEALTH AND HAPPINESS. By Dr. Paul Carton. New York: Dobseavage, 1928. 95 pp. Price, \$1.00.

LABORATORY MANUAL FOR THE DETECTION OF POISONS AND POWERFUL DRUGS. By Dr.

Wilhelm Autenrieth and revised by Wm. H. Warren, Ph.D. (6th ed.) Philadelphia: Blakiston, 1928. 698 pp. Price, \$6.00.

THIS SMOKING WORLD. By A. E. Hamilton. New York: Century, 1927. 227 pp. Price, \$2.50.

MOSQUITO SURVEYS A HANDBOOK FOR ANTI-MALARIAL AND ANTI-MOSQUITO FIELD WORKERS. By Malcolm E. Macgregor. New York: Wm. Wood, 1928. 293 pp. Price, \$5.50.

YOUR WEIGHT AND HOW TO CONTROL IT. Edited by Morris Fishbein, M.D. New York: Doran, 1927. 260 pp. Price \$5.00.

PERCIVAL'S MEDICAL ETHICS. By Chauncey D. Leake. Baltimore: Williams & Wilkins, 1927. 291 pp. Price, \$3.00.

MODERN BAKING POWDER. By Juanita E. Darrah. Chicago: Commonwealth Press, 1927. 125 pp. Price, \$1.00.

HEALTH READERS. Book I. THE SAFETY HILL OF HEALTH. Book II. BUILDING MY HOUSE OF HEALTH. By Jessie I. Lummis and Williedell Schawe. Yonkers: World Book Co., 1927. Book I, 96 pp., Price, \$.68. Book II, 141 pp., Price, \$.72.

GROWING UP. By Karl de Schweinitz. New York: Macmillan, 1928. 104 pp. Price, \$1.75.

NEWS FROM THE FIELD

NEW HOSPITAL AT WAUSEON, O.

WAUSEON, O., has been selected as the place for the fifth rural hospital in a series to be built by the Commonwealth Fund of New York in an effort to improve health and medical conditions of rural districts. The hospital will be a 50-bed institution, with a training school and it will be fully accredited. The local medical profession promises its coöperation.

T. B. ERADICATION WORK

THE results of coöperative tuberculosis-eradication work up to January 1, 1928, given in a summary issued by the Bureau of Animal Industry, U. S. Department of Agriculture, show unusual progress in combating this disease. The work of tuberculin testing has been going forward with unusual rapidity in recent months. The number of cattle tested monthly has ranged from about 900,000 to more than a million. The large number of cattle on the waiting list to be tested is regarded as evidence of the desire of livestock owners to avail themselves of the opportunity to free their herds from tuberculosis.

NEW DIVISION OF COMMONWEALTH FUND

THE Commonwealth Fund announces the establishment of a division of publications which will issue reports and studies dealing with the various activities of the fund. As part of its work the new division will continue the series of publications relative to the fund's program in the field of mental hygiene and child guidance, which was begun by the joint committee on methods of preventing delinquency. This committee, created for the demonstration period of the pro-

gram, has now been discontinued, and its staff has become the staff of the new division. The offices are at 578 Madison Avenue, New York, N. Y.

B. S. Pollak, M.D., F. A. C. P., is president of the New Jersey Public Health and Sanitary Association.

PHYSICAL DEFECTS IN SCHOOL BOYS

OF 2,000 boys between the age of 15 and 17 years who attend the East Side Continuation School in New York City, only 225 were found to be without serious defects in an examination sponsored by the New York Tuberculosis and Health Association. About half of the boys had diseased tonsils or decayed teeth, or both; over one-fourth were suffering from defective vision; considerable numbers were suffering from malnutrition, nasal obstructions and infections, and heart defects. Seventy-four boys had lung defects or diseases, including 6 with active tubercu-

losis and 31 tuberculosis suspects. While there were few cases of active tuberculosis, the excessive number of pathological conditions which contribute to lower vitality and resistance was of serious importance in relation to this disease.

HEART DISEASE IN CHILDREN

OF the 120,000 school children in Boston, Mass., 2,311 whose yearly physical examination by school physicians suggested a possibility of heart disease were examined by heart specialists. Of these 625, or one-half of 1 per cent of the total number of school children, were found to have organic disease of the heart; 77 were potential heart disease cases; 265 were classified as doubtful and needing re-examination from time to time. This record is not complete, because the survey only included those children well enough to attend school, and the method of examination may have missed many potential cases.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER

ON March 3, 1928, the American Society for the Control of Cancer will hold its Annual Meeting.

The Executive Committee and the Board of Governors will meet in the morning, at 10:30 o'clock. There will be an interesting exhibit, to which visitors are invited, of a demonstration of modern cancer research at the Crocker Institute of Cancer Research of Columbia University, by its director, Dr. Francis Carter Wood.

DR. KATHERINE B. DAVIS HONORED

A TESTIMONIAL dinner was tendered Dr. Katherine B. Davis on February 2, 1928, at the Hotel Waldorf in New York City, arranged by the National Council of Women.

Dr. Davis was born in Buffalo, N. Y., and graduated from Vassar in 1892. She became a Fellow in Political Economy at

the University of Chicago in 1897. She has received degrees from Vassar College, University of Chicago, Western Reserve University, Yale University and the Universities of Berlin and Vienna.

From 1901 to 1914 she was superintendent of the Bedford Reformatory for Women, and at that time Mayor Mitchell of New York City appointed her Commissioner of Correction. After the World War, Dr. Davis went to Europe for the Y. W. C. A., to do social hygiene work and to study the methods of European physicians in their work.

Dr. Davis recently retired from her position as Secretary of the Bureau of Social Hygiene.

EVERY CHILD'S DIETARY

"EVERY Child's Dietary for Mothers and Children" is a pamphlet recently prepared by Pearl S. Shackelford, nutrition advisor of the New York Tuberculosis and Health Association for the National Federation of Day Nurseries. In a foreword, Mrs. Herman N. Biggs, president of the Federation, states that the dietary was prepared with the mothers particularly in mind. "Our aim has been to present it in simple usable form, with recipes any one can use. It includes the proper proportion of calories, minerals, vitamins, etc." The dietary has received the commendations of Prof. Mary Swartz Rose, Henry H. Shaw, M.D., Charles G. Kerly, M.D., Alfred F. Hess, M.D., Charles Hendee Smith, M.D. and L. C. Schroeder, M.D., prominent nutritionists and pediatricians.

INFANTILE PARALYSIS PREVENTION

THE University of California has received, from an anonymous friend, a gift of \$5,000 a year during his life, and a fund of \$100,000 by his will to be devoted to the prevention and cure of infantile paralysis. The fund may be used, in case of necessity, to combat any serious epidemic which threatens the lives of children in California.

CONTRIBUTION TO DIPHTHERIA
PREVENTION

IN *State Charities Aid Association News* for December, 1927, an announcement was made that the New York State Outdoor Advertising Association will again contribute billboard advertising space for diphtheria prevention posters during 1928. They pledged space valued at \$25,000 for the year. During 1926 the value of the space contributed was \$11,000.

MARYLAND WATER AND SEWERAGE
ASSOCIATION MEETS

THE Maryland Water and Sewerage Association will hold a meeting at the Southern Hotel, Baltimore, Md., April 10 and 11, 1928.

Some of the papers presented will be: "Does the Municipality Know What It Costs?" by Thomas S. Durham; "Fire Insurance Savings and Water Works Design," by F. H. Dryden; "Garbage and Refuse Disposal for Small Communities," by William Raynor Straus; "Treatment of Water for Railroad Purposes," by R. C. Bardwell.

There will be papers on the question of stream pollution prevention and also a discussion of swimming pool sanitation. A field inspection trip is planned to the Towson Sewage Treatment Works and the Baltimore City Refuse Incinerator.

AN AMENDMENT WORTHY OF SUPPORT

AN amendment to the pending revenue reduction bill, which is of interest to members of the A. P. H. A. and members of state and county medical and public health societies has been proposed by Senator Arthur R. Robinson of Indiana. The amendment insures to all members of trades or business organizations the right to deduct from their federal income taxes, traveling expenses incurred in attending meetings of such organizations.

The passing of this amendment would

enable members of the A. P. H. A. and other professional societies to deduct travel expenses incurred by attendance at their meetings from their income tax. Members can urge their respective senators and representatives to endorse the amendment proposed by Senator Robinson.

THE LESLIE DANA MEDAL

THE fourth award of the Leslie Dana Medal, presented annually through the Missouri Association for the Blind to the person selected from the nominations received by the National Society for the Prevention of Blindness, will take place during the 1928 meeting of the American Academy of Ophthalmology and Otolaryngology, in St. Louis, Mo.

Nominations will be received by the National Society for the Prevention of Blindness, 370 Seventh Avenue, New York, N. Y., until May 15, 1928.

Items to be considered in making the nominations are: (1) Long meritorious service for the conservation of vision in the prevention and cure of diseases dangerous to eyesight; (2) Research and instructions in ophthalmology and allied subjects; (3) Social service for the control of eye disease; (4) Special discoveries in the domain of general science or medicine of exceptional importance in conservation of vision.

REORGANIZATION OF NEW YORK CITY
HEALTH DEPARTMENT

IN the reorganization of the New York City Health Department authorization has been given for the creation of a Bureau of Nursing, for the recreation of a Bureau of Public Health Education which has not functioned for several years, and for the consolidation of the Bureau of Child Hygiene, the Bureau of Preventable Diseases and the Division of Adult and Industrial Hygiene.

Louis I. Harris, M.D., health commissioner has announced the appointment

of the following directors of new bureaus and departments: Charles B. Bolduan, director, Bureau of Public Health Education; Amelia H. Grant, R.N., director, Bureau of Nursing; and Herman T. Peck, general medical director.

Speaking of the authorization by Mayor James Walker of this reorganization Dr. Harris explained: "It is a most substantial part of the scheme which was worked out after long study and after receiving the approval of the foremost health experts in the country. This reorganization is by way of housecleaning and to remedy the laxity and demoralization that was found to exist in the department at the beginning of 1926."

Under the direction of the Bureau of Nursing will be placed the 535 nurses employed in visiting homes, schools, and those engaged in clinical services or other field activities of the health department. The consolidation of the medical bureaus will be the first step in bringing about a mobilization of the medical field force of the health department to cooperate with the medical profession at large, in a strictly preventive capacity.

NEW YORK TUBERCULOSIS AND HEALTH ASSOCIATION

LINSLEY R. Williams, M.D., has been elected president of the New York Tuberculosis and Health Association to succeed James Alexander Miller, M.D. resigned, who has been president since the organization of the association. Dr. Williams is also managing director of the New York Academy of Medicine.

Walter M. Brunet, M.D., a member of the A. P. H. A., for several years director of the Division of Medical Measures of the American Social Hygiene Association has resigned to become executive secretary to the Committee on Social Hygiene of the New York Tuberculosis and Health Association. Dr. Brunet will serve as a consultant member of the A. S. H. A.

A. H. Flickwir, M.D., Fellow A. P. H. A., City Health Officer, Houston, Tex., is the representative to the A. P. H. A. from the Texas Association of Sanitarians

DR. MCCARTHY DIRECTOR HEALTH EDUCATION IN NEW YORK SCHOOLS

JOHN D. McCarthy, Ph.D., M.D., formerly head of the Department of Hygiene, De Witt Clinton High School, has been appointed director of health education of New York City Schools.

Dr. McCarthy is prominent in the health education field. He is an instructor in psychiatry at Columbia University and a member of the staff at Vanderbilt Clinic. For the past 4 years he has been an instructor in health education at New York University and also at Fordham University. Following his graduation from Dartmouth College he received his M.A. at Columbia University, his Ph.D. at New York University. Later he was graduated from Harvard Medical School.

FREE DISTRIBUTION OF PNEUMONIA
SERUM

FREE distribution of a limited quantity of the new pneumonia antibody solution for the treatment of lobar pneumonia has been inaugurated by the New York City Health Department. A grant of city funds to defray the expenses for the purchase of the serum has been obtained. Later a charge will be made for the product, but an amount will always be available free for charity cases. It is now available only to physicians who have cases which have been progressing for 3 days or more. The solution will be made in the New York City Health Department Laboratories, but a sufficient amount to supply all needs will not be ready until next fall.

NEW MEXICO

THE State Board of Public Welfare of New Mexico with the approval of Governor Dillon, will borrow \$2,500 with which to inaugurate the anti-malaria campaign in Dona Ana County. It is necessary to commence operations immediately against the malaria bearing mosquitoes which have already appeared and the emergency fund was needed before county money could be made available. Dr. C. W. Gerber, County Health Officer, has worked out the details of the campaign.

STATES COÖPERATE ON STREAM
CONSERVATION

MARYLAND, Pennsylvania, Ohio, West Virginia, Kentucky, New York, Indiana, Illinois, and Tennessee have entered into an agreement for interstate stream conservation which provides for joint sanitary control over the waterways in these states. The agreement has been made through the departments of health of the 9 states. The agreement insures the protection and conservation

of adequate and safe water supplies for drinking and commercial use.

An advisory board composed of the chief engineers of the 9 states will advise on the policies and methods of sanitary engineering problems involved.

PENNSYLVANIA PUBLIC HEALTH
ASSOCIATION

THE Pennsylvania Public Health Association held its annual meeting at Philadelphia, February 13-14.

The officers elected for 1928, are: President, J. C. Reifsnyder, M.D., Scranton; First Vice-President, J. T. Butz, M.D., Allentown; Second Vice-President, John M. J. Raunick, M.D., Harrisburg; Secretary-Treasurer, Wm. C. Miller, M.D., Harrisburg; Assistant Secretary-Treasurer, Edgar S. Everhart, M.D., Harrisburg.

Those elected to the executive committees are: Theodore B. Appel, M.D., Harrisburg; Thomas W. Henderson, Washington; W. E. Matthews, Johnstown; Thomas Herbert, Altoona; C. B. Auel, Pittsburgh, and H. C. Frontz, M.D., Huntingdon.

TEXAS

THE First Short School for Dairymen and Milk Dealers in San Angelo, Tex., and adjacent territory was held at San Angelo, February 23 and 24. The school was arranged under auspices of the Dairy Division, the Board of City Development, the City Health Department, the Texas Association of Sanitarians, and the State Department of Health. The economy of high grade dairying, dairy barn construction and sanitation, the standard milk ordinance inspection code, demanding health examination certificates from dairymen and food handlers, and milk as a food were among the topics discussed by experts.

PERSONALS

Drs. William F. Passer, Twin Falls, Ida., and George F. Ashley, Montpelier, Ida., have been appointed members of the state medical board, and Drs. Frank W. Almond, Boise, Delos E. Cornwall, St. Maries, and Charles F. Hanmer, Salmon, reappointed members of the board for 1928.

Dr. George H. Lowthian, formerly of Milbank, S. D., has joined the staff of the veterans' hospital at Boise, Ida., succeeding Dr. William S. Titus, who resigned.

Dr. T. Restin Heath, formerly medical superintendent of the Flint-Goodridge Hospital, New Orleans, La., has been appointed superintendent of the Bethany Hospital in Kansas City, Kan.

Dr. James H. Huddleson, Jr., has been appointed consulting neuropsychiatrist at the U. S. Veterans' Hospital 81, New York, N. Y.

Dr. Bruno S. Harwood has resigned as head of the sanitary department of the board of health on Staten Island, effective February 10, and will assume the superintendency of a tuberculosis sanatorium in Sullivan County.

Dr. Andrew J. Crowell, Charlotte, N. C. was elected president of the North Carolina State Board of Health, January 23, to succeed the late Dr. Joseph Howell Way, who held that position for about 15 years.

Dr. Elijah B. Pickel, Medford, Ore., has been elected president of the Oregon State Board of Health to succeed Dr. Willis B. Morse of Salem. Dr. Harold C. Bean was elected vice-president and Dr. Frederick D. Stricker, secretary.

Dr. Philip W. Boyd, Winchester, Va., was elected president of the Virginia State Board of Medical Examiners to succeed the late Dr. Robert Glasgow.

Dr. Arthur H. Cohn has been appointed chief police department surgeon of Milwaukee, Wis.

Dr. Claus T. Droege, New York, Wis., has been appointed prison physician of the state penitentiary at Waupun, succeeding Dr. Wallace P. Smith, who held the position since the recent death of Dr. John F. Brown.

C. G. Crow has been appointed city health officer of Oroville, Calif., to succeed John O. McAtee.

Dr. T. Dwight Sloan of Ohio has been appointed Superintendent of the Post Graduate Hospital, succeeding Col. Louis G. Trimble, who resigned.

Dr. W. M. Taylor, health officer of Mooers, Clinton County, N. Y., for 20 years, died on January 13.

Dr. Frederick A. Hemsath, a former member of the staff of the New York State Laboratory, has been appointed director of the Cattaraugus County Laboratory.

Dr. John H. Korus has been appointed superintendent of Rocky Crest Sanatorium at Olean, Cattaraugus County, N. Y.

Dr. William L. Somerset, chief diagnostician of the New York City Health Department died January 11 from thrombosis while undergoing an operation for appendicitis. Dr. Somerset was associated with the city health department for over thirty-five years and was widely known for his diagnostic ability in communicable diseases, especially smallpox.

Dr. S. H. Bennett of Little Valley, Cattaraugus County, N. Y., died January 1. Dr. Bennett was health officer of the town of Greenwood from 1909 to 1918, of the town of West Union from 1912 to 1918 and of the town and vil-

lage of Little Valley from 1918 to the date of his death.

Dr. Albert Mueller has been appointed city physician of Rock Island, Ill., to succeed the late Dr. Joseph Hollowbush.

Hazel Goff and Mary Elizabeth Tennant have been appointed field directors of the Paris Staff of the Division of Medical Education of the Rockefeller Foundation.

Miss Alma C. Haupt, assistant director of the Commonwealth's Fund Division for Austria, has been transferred to the staff of the New York office and will be in the division of Rural Hospitals.

Dr. J. A. King of Ojai, Calif. has been appointed health officer of Ventura County, to succeed Dr. A. A. Maulhardt.

Dr. I. C. Riggin, former health commissioner of Lorain County, O., general health district, has been appointed associate secretary on the staff of the Cincinnati Public Health Federation. He will direct the programs of the heart council and the cancer council.

The Department of Soldiers' Civil Re-Establishment of Canada has been transferred to the jurisdiction of the Department of Public Health and Dr. J. A. Amyot, C.M.G., Deputy Minister of Health will be Deputy of both branches.

Dr. Charles E. Shultz, health director of Bloomington, Ill., has resigned to become superintendent of Fairview Sanatorium of Illinois.

Dr. Michael A. Cunningham, formerly assistant superintendent of the tuberculosis hospital at Oakdale, Ia., has become medical director of the Holy Cross Sanatorium at Deming, N. M.

Dr. James W. Bazell has been appointed health officer of Winslow, Ariz., to succeed Dr. John R. Walls.

Dr. James R. Dykes, of Marshallville, Ga. has been appointed health officer of

Grady County, Ga. He will succeed Dr. Mannie A. Fort who has had charge of the health work in both Grady and Decatur Counties. The combined county health program could not be continued according to report, since state and federal aid had been exhausted.

W. G. Stronquist has resigned as director of the division of sanitary engineering of the health department, Memphis, Tenn. to accept a similar position in Birmingham, Ala.

Dr. Augustus A. Oliver, Paris, Tenn., has been reelected county health officer. He is also city health officer of Paris and has been in public health work for about 20 years.

Dr. George D. Butter of Pulaski, Tenn. has been elected health officer of Giles County, Tenn.

Olive Chapman, formerly with the New York County Chapter of the Red Cross is now executive secretary of the chapter at Greenville, Miss.

Dr. Nelson A. Bryan, formerly of Atlanta, Ga., sailed on January 17 for the Southern Baptist Mission Hospital at Hwanghsien, China. He will be the only American physician connected with the hospital.

Dr. Ray S. Dixon, director of venereal clinics, department of health, Detroit, Mich. delivered the De Lamar lecture on hygiene at the Johns Hopkins School of Hygiene and Public Health, January 24, on "Factors in the Control of Venereal Disease."

Dr. John Sundwall, professor and director, division of hygiene, public health and physical education, University of Michigan Medical School, Ann Arbor, Mich., was elected president of the Michigan Public Health Association at its 7th Annual Meeting at Lansing, Mich., January 13.

Hibbard R. Norman, Health Officer of New London, Conn., has appointed

Experience With the Program of Cancer Control in Massachusetts

GEORGE H. BIGELOW, M.D., D.P.H.

and

HERBERT L. LOMBARD, M.D., M.P.H., FELLOW A.P.H.A.

Commissioner of Public Health, and Epidemiologist, Massachusetts Department of Public Health, Boston, Mass.

MANY changes have occurred in the Massachusetts death returns in the past twenty-five years. The death rate for all causes has dropped from 1,695 per 100,000 in 1901 to 1,256 in 1926. The median age at time of death for all causes has increased from 38.8 to 57.8 years.

The rates for many of the individual diseases have shown material changes. Among these are typhoid fever, which has decreased from 19.7 to 1.4; scarlet fever which has dropped from 13.5 to 2.78; diphtheria which has declined from 34.3 to 5.9; and tuberculosis which fell from 235.0 to 83.4. During this same period, however, the circulatory diseases have increased from 163 to 309, diabetes from 11 to 19.8, and cancer from 73 to 127. Fifty years ago the chronic degenerative diseases comprised one-eighth of all deaths. Today they comprise over one-half.

While other factors than public health accomplishments have been instrumental in lowering the rate of some of the diseases, there can be no doubt that part of the decreases have been the direct result of this work. Better diagnosis will account for an additional part of the seeming increases. Regardless of the reasons for the increase in the degenerative diseases, it is apparent that these diseases are fast replacing others as causes of death, and public health measures should be instituted toward their control.

The Massachusetts Department of Public Health has started a campaign against the degenerative diseases by inaugurating a cancer program, as the cancer situation seemed more urgent than that of any of the other diseases in Massachusetts. A comprehensive study of cancer with the facilities for its control was first made. This included a review of the cancer literature, surveys in selected towns and cities, questionnaires to doctors, hospitals, and overseers of the poor, a statistical study of the cancer death records, and numerous interviews with recognized authorities on the disease.

In 1842 the cancer death rate was 13 per 100,000; in 1860 the rate was 26; in 1900 it was 71; while in 1926 it was 126.8. That this increase is not all real is obvious. In the early years many deaths which were undoubtedly due to cancer were certified as senility, stomach trouble, or unknown cause. Even at the present day, there is still confusion in diagnosis, and the rate of 126.8 is probably too low, but when allowance has been made for improvements in diagnosis and better certification, there still remains a definite increase in the cancer death rate. This increase in rate present in both sexes, is greater among males than females. In the female group there has been a tendency for the curve of cancer death rate to flatten. This was so marked in 1926 that there were 300 less deaths than might have been expected from the study of the long-time trend.

In the years 1920 to 1925, Massachusetts had the highest cancer death rate of any state in the Union, when adjustments had been made for age and sex distributions. In this same period, New York was second, Rhode Island third, and Connecticut fourth, while many of the southern states had very low rates.

The average person waits about 8 months between the first symptoms noted and the first consultation with a physician. Boston citizens wait one-half a month longer before submitting to an operation than do the residents of the state outside Boston. When we know that the chance of cure decreases as much as 16 per cent per month in one type of cancer, it is apparent that the long delay is the cause of many needless deaths. At the present time, in Massachusetts there are a sufficient number of hospital beds to care for all operative cases, but there is a need for more beds for terminal cases. With the present delay in seeking medical advice, the number of terminal beds needed in Massachusetts is about 10 per cent of the number of yearly cancer deaths. If the 8 months' delay can be appreciably reduced, the number of terminal cancer beds needed will likewise be reduced. Facilities for x-ray and radium treatment are not uniformly available throughout the Commonwealth.

Our cancer control program is divided into four parts: hospitalization, clinic, education and investigation.

The hospitalization program has two aspects: one dealing with immediate care for the patient, the other with the determination of a long-time policy for such cases. The Pondville Hospital, renovated and opened in 1927 to receive cancer cases, is meeting in part the first of these needs. Here, 90 cases can be cared for, two-thirds of them bed patients and the remainder ambulatory. The hospital is being conducted in the most approved manner. The service given is adequate and equals or excels that obtained elsewhere. A visiting committee supplemented by a special worker is endeavoring to furnish a home-like atmosphere in the institution.

Perhaps the most important part of the project, as far as quality of service is concerned, is the consultative staff from Boston. Every effort is being made to admit as many early stage cases as possible for diagnosis and treatment in order to keep down the death rate and minimize the stigma likely to become fastened to an institution largely serving incurable cases. Early stage cases can be sent from nearby clinics as they develop. Only patients not otherwise able to obtain institutional services are accepted. Should institutions already handling incurable cancer begin transferring their patients, the 90 available beds at Pondville would soon be filled without in any way meeting the need for which it was meant.

The number of cancer patients applying furnishes facts for any program of expansion as well as suggestions for a policy for other chronic diseases. The question of centralization against decentralization as applied to hospitalization can be fairly answered after a few years' experience at Pondville. Will the patient come to a central institution to die, or will he prefer to remain near home? In tuberculosis it has frequently happened that the dying patient insists on returning home. Before embarking upon a large program of central hospitalization for cancer we must know whether our experience with this disease will be the same.

How much can be done for the cases in their homes? Hospitalization for chronic cases is the most expensive form of care. It is estimated that adequate hospitalization for a cancer patient will cost at least \$35 a week. In the 6 months that the Pondville Hospital has been in operation there have been 168 admissions. This number is too small to draw conclusions of any character.

With over 5,000 deaths annually from cancer in Massachusetts, and with the cancer death rate steadily on the increase, it seems absurd to await complacently the discovery of some medical cure for cancer

before undertaking measures for the control of the disease. Such an interval of waiting in tuberculosis would have been inexcusable. For the state merely to furnish a hospital or home for the individual with cancer to pass his last days in some degree of comfort is equally shortsighted. A state cancer program must be broader and include measures which attempt to reduce the number of hopeless cancer cases.

With our present knowledge, the cure of cancer is only possible when diagnosis is made at an early stage of the disease, and prompt treatment instituted. In our study of clinic cases we have found that the average cancer case comes to the doctor 7.4 months after the first symptoms, but even then, many of them delay longer before having adequate treatment.

Any program which will successfully lower the cancer death rate must attack the delay on the part of the practicing physician as well as on the part of the patient. The most rational method of attacking these obstacles is by means of the cancer clinic.

The clinic will first give an opportunity for individuals to receive diagnostic service. It will be composed of a group of physicians recognized in their community, who are all thinking in terms of cancer. Any individual regardless of his financial standing may receive an opinion from this group. Those able to pay will be referred from the clinic to private physicians, while those unable to pay will be referred elsewhere and followed up for care and treatment.

That expert advice on cancer is needed for early diagnosis can be readily appreciated when it is realized that the average physician in Massachusetts sees between 4 and 5 cases per year, and these of different types. As each type demands a different kind of skill in its diagnosis, a physician seeing fewer than 1 case a year of a given type cannot be expert. The staff of the clinic will be composed of a group, each seeing many cases of the type of cancer peculiar to his own specialty. The interest in cancer among the profession will be further increased by consultation visits supplemented by forum discussions by experts from the larger centers. Such group specialization in fractures, goiter therapy, etc., has accomplished much in improved quality of service.

The surgeon will find patients more readily accepting his advice when it is supplemented by that of the clinic group. Where clinics have been functioning it has been found that many persons who refused to take the surgeon's advice regarding early operation, after attending clinics and having the same advice given them, returned to their surgeon for treatment. The community spirit aroused by the clinics will have a tendency to keep the subject of cancer before the lay public, and

can react only favorably in getting patients under treatment at a much earlier stage than is the case at present.

The department is endeavoring to establish clinics in a number of strategic centers. Since a cancer clinic demands not a single physician, but a group of specialists including the surgeon, the general medical man, the pathologist, roentgenologist, rhinologist, urologist, gynecologist, etc., and since its needs are not limited to the four walls of the clinic room, but demand the full resources of a modern hospital, the department has decided to stimulate clinics first in those communities that have the most to offer in professional coöperation and hospital resources.

An opportunity is asked to present the program to the organized medical profession of a given city. If it seems suitable, the local medical profession passes a vote of support to the program and authorizes the appointment of a local medical cancer committee. This committee is responsible for determining where the clinic or clinics shall be held, for outlining the policies, organizing the staff, supervising the quality of service, and directing the growth. The department meets with this committee to determine how it can best assist with its resources in personnel, supplies and funds.

The medical committee also appoints a local lay cancer committee. This latter must determine such matters as education of the local public in regard to available resources and their proper utilization, and must face the unutterable, tragic, social and economic problems which will be uncovered, as well as decide the best solution of home or hospital care for the incurable, since many will not want to die in a remote institution. The department has personnel and other resources for these lay committees, but each community must be sufficiently stirred to the need of largely meeting its own problems. Too many sound programs have failed because of local indifference or antagonism.

Each clinic is required to furnish a social worker. She will be appointed by and under the direction of the local committee. She will attend all clinics; be responsible for all special records and reports; will do the follow-up work and visit patients in their homes to see that they are receiving proper treatment and care. She will coördinate the clinic with other community social and welfare agencies, both local and state. In many cases, she will diagnose the social and financial status of the patients and plan for their further treatment or hospital care.

The minimum standard training for such a worker is graduation from a recognized school of social work, including a course in medical social service, or graduation from a recognized training school for nurses plus a course in public health nursing, or two years of general

case work with a recognized social agency and a year's experience in medical social work.

The department has a medical social worker whose duty will be to coördinate the social work in the various clinics and to find means by which follow-up work may be carried on in the non-clinic communities. The policies of social service as it relates to cancer control will be further worked out by the department with the aid of our advisory committee composed of leaders in the social and nursing field. Publicity will also be needed to disseminate facts regarding the possibilities of prevention and cure of cancer in its early stages.

In some localities the clinic is a single hospital, while in others the clinic has branches in several hospitals, and meets at different times in each of them. While the staffs of the different branches vary, there is but one management and one social worker.

Cancer clinics have already been developed in 6 communities, and within a few months this number will be increased to 12 or 13. The first clinic was organized on December 17, 1926, and the sixth on June 30, 1927. Up to January 1, 1928, 1,360 individuals have attended the clinics.

In the records are many facts which may be instrumental in determining our future policies. Thirty-one per cent of the clinic attendance has been men and 69 per cent women, and 23.1 per cent were found to have cancer. Of the group having cancer 68.8 per cent were reported to be in the operable stage. The median age of the non-cancerous individuals who attended the clinics was 46 years, while that of the cancer patient was 60 years. Of those coming to the clinics 61.6 per cent came because of newspaper publicity, 20.1 per cent at the advice of a physician, and 18.3 per cent for other reasons.

The symptoms which the cancer patients presented are classified as follows:*

Swelling	36.8	Ulceration	9.0
Pain	44.8	Deformity	2.8
Loss of Weight	8.2	Malaise	4.1
Discharge	13.9	Scaly skin	1.7
Itchings	0.7	Bleeding	0.7
		Unknown and Others	7.1

* As many patients had more than one symptom, the total is more than 100 per cent.

The location of the disease was as follows:

	Per Cent		Per Cent
Buccal cavity	22.6	Male genitals	1.6
Stomach, liver group	2.5	Breast	19.1
Peritoneum, intestine, rectum group	4.8	Other organs	1.6
Skin	30.2	Unspecified	3.8
Female genitals	13.4	Not stated	0.3

Of the individuals with cancer 14 per cent had never consulted a physician; 43.3 per cent had consulted one physician before coming to the clinic; while 33.1 per cent had consulted more than one physician, and the remainder gave no information.

The department has appointed an advisory committee to determine the best methods of publicity. One member of this committee is the state chairman for Massachusetts of the American Society for the Control of Cancer. This organization is a great aid in the state's program. At present the state is distributing literature, furnishing newspapers with material, as well as maintaining a speaker's bureau. Efforts are being made to get into closer touch with the local organizations and to interest them both in the state's program and the disease itself.

In the clinic centers the local lay committees will have charge of all publicity. Many cases will be brought to the attention of the committee. It will make arrangements for individuals who either cannot or will not avail themselves of the facilities at Pondville or elsewhere. One of its functions will be to study community resources and see in what way such problems can be solved. With sufficient interest aroused, money may become available for beds and wards to be added to existing institutions, in some instances, and for special hospitals in others.

The educational campaign should stress the following facts:

1. At first in all cancerous processes, cells in some part of the body begin to multiply. At this stage, the process is purely local and if the cells are completely removed, there will be no further recurrence of the cancer; if not removed, cells may wander to other parts of the body, and by increasing in number, may form new growths there.
2. Cancer cells in various localities act differently: cancer of the skin is a slow growing cancer and not particularly malignant; cancer of the breast is a more rapidly growing cancer and more malignant; while cancer of the mouth grows very rapidly and is extremely malignant.
3. Cancer is a disease largely confined to late adult life.
4. Cancer is often preceded by long continued irritation. Measures used to prevent such irritation should be adopted. Among these may be mentioned: improved dentistry, abstinence or limited use of tobacco and alcohol, treatment of chronic mastitis, repair of lacerated cervix, more exercise and less food.
5. Any continued irritation, any lump, any abnormal discharge, any sore that does not readily heal, any wart or mole that changes in size and appearance should arouse suspicion and send the individual to his physician.
6. Pain may not be a symptom of early cancer, and people should not wait for its appearance before consulting a physician.

Hospitalization will care for the terminal cases; clinics will aid in reducing the volume of hopeless cancer; but these will not lower the incidence of the disease.

Although mortality figures and hospital records for this disease are available and have been freely studied, little is known regarding cancer

morbidity in the community at large. The physicians of Newton, Mass., are, therefore, conducting a morbidity study. The number of those who die of cancer can be ascertained, but as the individuals who had cancer and have been cured are usually reticent regarding their condition, the exact number of cures is unknown.

The visiting nurses throughout Massachusetts are completing questionnaires which give in detail information regarding the habits of the cancer patient. Similar information is obtained from a non-cancerous patient as a control. When a sufficient number of questionnaires are available, any difference which may exist between the habits of the cancer patient and the non-cancerous individual can be noted, and studies can be made to determine whether these differences are significant.

Two morbidity surveys have been made in which all householders in 2 towns were interviewed. When these figures have been completed and tabulated, information regarding other degenerative diseases beside cancer will be available.

The death records of all cancer patients are being tabulated. From them we have already learned facts concerning the prevalence of cancer, the ages at which it is most common, the life duration of those with or without treatment, the geographical distribution, the relation between cancer and population density, and the relation to nationality.

When a patient presents himself to one of the state-aided cancer clinics, a few questions are asked regarding the symptoms and what induced him to come to the clinic. It is felt that the average patient presenting himself should be questioned as little as possible owing to his emotional strain; and extensive questioning of patients might tend to decrease the attendance. The few facts obtained, however, will furnish valuable data on the social aspects of the disease and the value of the various forms of educational publicity.

To determine the effectiveness of the Massachusetts state cancer program will be a problem for the future. But because of widespread interest in the disease, community interest is relatively easy to obtain, and in any preventive program community interest is the head-stone of the corner.

Free Dental Treatment for Cuban Children

FREE dental treatment has recently been established by the Cuban Department of Public Health for public-school pupils of Habana and nearby towns, when their parents cannot afford to pay for such service. To facilitate the service for suburban children conveyances have been provided to take them to the dental offices.

The Prevalence of Rabies in the United States and the World*

THURMAN B. RICE, M.D.

Indiana University School of Medicine, Indianapolis, Ind.

and

NORMAN BEATTY, M.D.

Formerly Director of Indiana State Board of Health, Pasteur Laboratory

RABIES deserves to be considered one of the most important of health problems. The number of deaths is not appalling but the suffering and fear caused by it are so great that they make this the most dreaded of all diseases. The co-authors of this paper, having both served at different times as director of the Indiana Pasteur Institute and, having seen the great increase in the disease in that state, determined to find to what extent this condition prevailed in other states and in other parts of the world. Data on the subject are fragmentary, hard to get, and not at all reliable.

Questionnaires were sent to the health officer of every state in the Union, to all the provinces of Canada, and to practically all foreign countries, asking for data on rabies in man and in animals. By this and other means information was received from every state though not always was the information complete. Medical literature was exhaustively searched for references to geographical distribution of the disease and for evidences of its increase or decrease. About thirty foreign countries answered our letter—a most interesting correspondence. A voluminous letter from Japan is still untranslated.

From this large mass of evidence we have endeavored to sort out the salient facts, though we are keenly aware of the fact that much of the data is conflicting, as for example the total number of human deaths as reported to us by states, and as reported by the Bureau of the Census for the U. S. Registration Area.

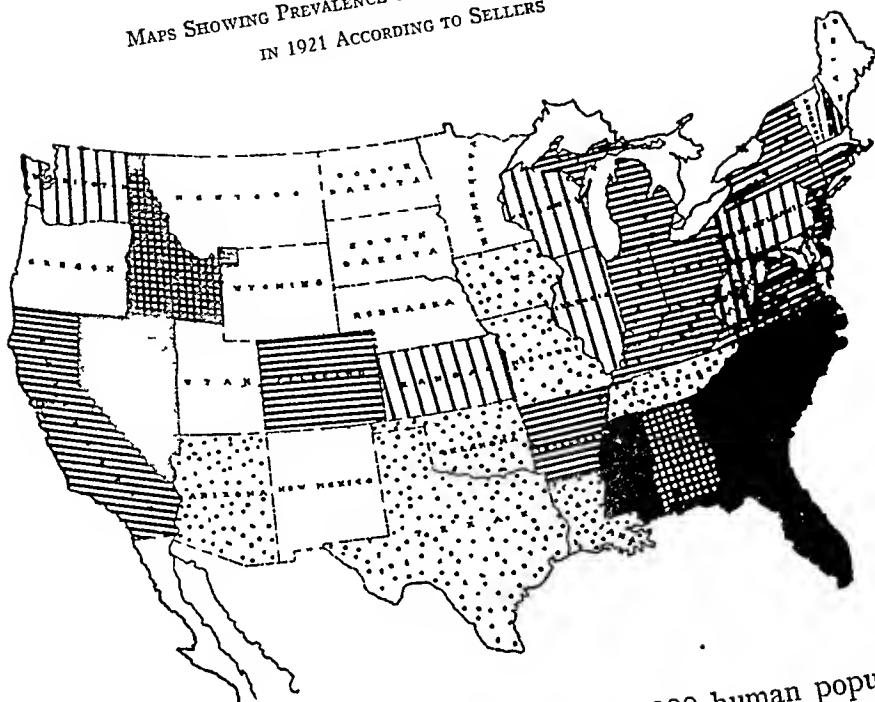

In order to show present conditions in as graphic a manner as possible we have attempted to shade a map of the United States to represent the prevalence of rabies. This map was made as nearly as possible on the same scale as another published by Sellers¹ representing conditions in 1921, also presented here. Sellers's shading is made on basis

AMERICAN JOURNAL OF PUBLIC HEALTH

FIGURE 1

MAPS SHOWING PREVALENCE OF RABIES IN UNITED STATES IN 1921 ACCORDING TO SELLERS

of the number of cases in animals per 100,000 human population—not a very satisfactory basis but the best that could be devised under the circumstances. Frequently in the case of our investigation such a source of information was evidently unreliable, and in such event any other available source of information was used. If, for example, the number of human deaths for a given state was high that state was made black even though the number of cases in animals reported was low (incomplete returns). The state of New York was made black on basis of various references to the condition in medical literature. Texas was made black on the strength of newspaper reports and records of companies selling rabies vaccine. Such sources are not highly satisfactory, but we believe that with this explanation their use is justifiable.

It is interesting to note that Kerr and Stimson³ found little of this disease in the western states in 1908. They report that California, Idaho, Nevada, and New Mexico were free of the disease, while in 1926 these states were heavily infected. Indeed, California has had more deaths (human) in recent years than any other state of which we have record (68 deaths since 1909). California shows two peaks in her epidemic, 1912-13 with 9 and 8 human deaths respectively, and 1923 with 11.

FIGURE II

RABIES IN THE UNITED STATES IN 1926
 MAP MADE ON THE SAME BASIS AS THAT OF SELLERS
 AS FAR AS WAS POSSIBLE

KEY

Dotted	no data								
White	no rabies								
Vertical lines	less than one	positive head per	100,000 human population						
Horizontal lines	one to five	"	"	"	"	"	"	"	"
Crossed lines	five to ten	"	"	"	"	"	"	"	"
Solid Black	ten or more	"	"	"	"	"	"	"	"

The following states reported that the disease is now increasing or has done so in very recent years: Arkansas, California, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Massachusetts, Michigan, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Pennsylvania, South Carolina, Tennessee, Virginia, West Virginia, and the District of Columbia.

If we pin our reliance upon figures it would seem that there has been a very great increase in certain states (See 4 charts).

Considering the seriousness of this disease both in man and animals it is quite surprising that there are so few reliable records. The loss of stock and the expense of giving treatment to man and beast must cause the expense of this strictly preventable disease to mount well into the millions of dollars each year. The loss of human life is by no means inconsiderable. Apparently the most reliable records are those of human deaths reported to the Bureau of the Census.

Rabies in other countries than our own may be of some interest. The data presented is from questionnaires and from the literature.

Canada—Since the map of the United States shows very little rabies in the northern states we might expect still less in Canada. Our data bear out this expectation, though we know there is some of it in the Arctic regions.

Alberta—No record of any case in ten years.

British Columbia—Only one case in any animal known, and this was in a dog brought in by a tourist. No human deaths.

Manitoba—Some rabies in animals. No human deaths.

New Brunswick—None since 1918. No records previous to that date.

Nova Scotia—None in animals or man.

Ontario—After several years' freedom from the disease it was introduced from Quebec and quickly spread. Forty-one positive brains were examined in 1926. No human deaths.

Prince Edward Island—Questionnaire not answered.

Quebec—Rabies spreading rapidly from two foci. No human deaths.

Saskatchewan—No rabies 1926.

Alaska—Not common but has been observed particularly in wolves and foxes.

Arctic Regions—Nansen mentions the occurrence of rabies in "Farthest North," and it has been reported from Greenland.

Mexico—Rabies is very common. There are many Pasteur Institutes and thousands of treatments are given annually. The number of human deaths is rather large but exact information is not available.

Cuba—Has been epidemic to a serious degree in recent years.

South America

Ecuador—Not common.

Venezuela—Rare in animals and extremely so in human beings.

Argentina—Fairly prevalent.

Brazil—It has been epidemic at different times especially in the north.

El Salvadore—Present.

From incomplete returns we may reasonably conclude that the disease is present in moderate amount in the greater portion of the continent.

Europe

Belgium—There has been very little rabies except during the Great War when antirabic precautions were relaxed. During times of peace elaborate precautions are taken to prevent its introduction. These methods have been highly effective.

England—By strict muzzling ordinances, England was able entirely to rid the country of the disease in 1902. After that time there was none until 1918 when the disease was re-introduced. It spread rapidly but has again come under control and there has been none since 1922.

France—The home land of Pasteur has long been seriously plagued with rabies. In 1913 it was almost eradicated but flared up again during and after the Great War to alarming proportions. It is at present declining.

Germany—The rabies situation was well in hand before the war, there being on the average 300 to 400 cases in animals annually. In 1915, it rose to 1018, after which there was an irregular increase to 2699 in 1924. Since that date the condition has improved and is greatly reduced in 1927. Human deaths were as

follows: 1924, 48; 1925, 20; 1926, 22. Persons bitten by rabid dogs for the same years were 2417, 1159, and 579 respectively.

Holland—Because of very rigid control measures there were no cases of rabies in Holland previous to the Great War. During that crisis there was some in the borders of the country but again none since.

Ireland—There has been no rabies for twenty years. All immigrant dogs are quarantined for six months.

Russia—No communication was received from this country, but it is well known that the rabies situation there is very serious, perhaps the worst of any country in the world. The disorganized state of the government, the prevailing ignorance, and the vast territory involved makes the situation well nigh hopeless.

Sweden—There has been no rabies since 1886 when there was one case in an imported animal. Strict regulations govern the importation of all members of the dog family.

Switzerland—Rabies is rare. Three hundred and twenty-nine Pasteur treatments were given in the quarter of a century just closed, and there was one human death.

Austria—Has been epidemic in recent years.

Italy—No very recent data, but has been quite common for a long time.

Balkan States—It has been an important problem here since the Great War and the years immediately preceding.

Spain and Portugal—Rabies very important public health problem.

Africa

Egypt—Rabies is very common among the countless homeless dogs. There is little effective control of the situation. The number of cases treated trebled from 1914 to 1924, but has decreased since. One thousand two hundred and fifty-one treatments were given in 1926 at Cairo alone.

Union of South Africa—fairly common in animals, and occasional cases in human beings.

Occidental French Africa—Rabies present but not prevalent.

Western Africa—Rabies is common.

Asia

Palestine—Rabies is very common.

Arabia—Common in the settled portions.

India—Data from the Pasteur Institute at Calcutta for the province of Bengal (population, 40,000,000): 1924 (7 months) 1995 patients treated, of whom 17 died; 1925, 5585 cases treated of whom 33 died. Total deaths for Bengal (human) 304 in 1925.

Japan—A very serious public health problem.

China—Rabies was known in the time of Confucius and has been a serious problem continuously to this day.

Siam—Very common.

Siberia—Very prevalent.

Tibet—Prevalent.

Oceanic Islands

Australia—Free of rabies and has always been so.

Hawaii—Free of rabies. All animals from foreign ports are quarantined for 128 days.

Philippines—Rabies is very common among the many dogs. Human deaths were 103 in 1925; 93 in 1926.

Dutch East Indies—Fairly common.

SUMMARY

1. Rabies is on the increase in the United States, or at least was so two years ago.

2. It increased in Europe during the Great War but has declined somewhat during the last three to five years there.

3. It has been completely eradicated from certain countries, while in others it has apparently never existed.

4. In the main, rabies is more prevalent in those parts of the world where civilization is retarded, and poverty prevails.

DISCUSSION

Dr. Strauss, Virginia—I can only second what Dr. Rice has said as to the extreme difficulty in getting reliable figures on the subject. A few years ago we checked up on the human deaths, and found that the only figures upon which we could place any dependence were numbers of positive dogs heads reported. We get that information not only from our own laboratories, but from the Washington laboratories who report all positive heads that they get from the northern part of Virginia. In that way, we are able to follow fairly well the progress of the disease through the state.

A few years ago, there was a very obvious increase along the entire southern border, which increase appeared to move gradually up through the state. By the time it reached the central section, it began to drop off, and this year we have a very decided decrease in the amount of rabies. Concerning our positive heads, for a fixed 8 months for 1925, 1926 and 1927, we find that in 1926 we had an increase of 57 per cent over 1925, while in 1927 we have a 30 per cent decrease under 1926. I believe the disease is really decreasing, temporarily at least, with us in Virginia.

I had the opportunity to watch a very definite epidemic in Richmond a year ago last spring. We had gone for a 2-year period in Richmond with no rabies at all, then in the suburbs there appeared one or two cases, which spread with great rapidity until it covered the entire city. There were three or four hundred dogs with the infection—fortunately no human cases. There was issued an ordinance at that time, compelling muzzling or confining of all dogs, and it seemed as though the dogs could read the ordinance, because there was an immediate decrease in the disease. What we think helped largely was the fact that the city put on extra dog-catchers, and almost completely rid the city of stray dogs. The stray dog is, of course, the real menace.

Dr. Howell, Springfield, Ill.—In 1923 in Illinois our rabies troubles began just as they did in Indiana. The first year, the trouble was confined to the southern part of the state, coming across the Wabash River. Gradually it spread northward. It has now reached the northern part of the state, and the city of Chicago is getting each month as many positive dog heads as it had for an entire year formerly. In the southern part of the state, the disease is falling off.

By plotting the cases geographically, and comparing your monthly returns with the normal rates, you can pretty nearly predict how long your epidemic is going to last. We have just passed through the time of year—August and September—when rabies should be at its lowest. However, Chicago has had a rather sharp increase during those months, indicating that next spring, perhaps, there will be a

very marked increase in the disease there. It would seem that they cannot expect a decrease until a year after next, unless stringent measures are taken. The southern part of the state will rapidly clear itself of the disease, I believe.

The matter of the stray dog interested me, and therefore, with every positive head we have, we send out a little slip to find out how many other dogs had been bitten, etc. Just before I came to Cincinnati, I tabulated my results and received 75 answers. Thirty-five of the dogs that had been examined in 4 different laboratories in Illinois were strays, and the owners of the remaining 40 were known. The 75 dogs had bitten 58 persons, 136 other dogs and 14 other animals, such as horses and cattle. The stray dogs may have bitten more dogs than those of which we have a record, but it is pretty easy to check up the number of people bitten, because we hear of those. It would seem that the stray dog is of great importance in disseminating the disease among other dogs, and not as much of a menace to people.

Dr. Shore—Rabies has always had a very unique interest in that it so completely differs from all other known diseases. We know more about it than we do about any other disease, and the feature which I want to emphasize here is that we know exactly how to exterminate it. We do not know that about any other disease, unless possibly it is yellow fever, and it is not very much of a compliment that we have such a large amount, and that only such countries as Russia and India exceed us greatly in numbers.

The International Conference on Rabies which was held in April discussed this disease from several angles. The resolutions adopted at that conference have been put into print. I think, among those resolutions, the most important was the last paragraph which read something like this: That the Conference believed and was agreed that rabies could be exterminated only by the restriction of the liberty of the dog unless muzzled or confined to the premises of the owner, and the extermination of the ownerless dog and it moved that the resolution be embodied in all the countries in the world. This has already been done in Great Britain and in the Scandinavian countries. That is the only way that we are going to get rid of the disease here. We know it is absolutely impossible to get every dog vaccinated and to vaccinate them every year. It is also going to be very difficult to pass and enforce adequate dog laws in this country, but it is less difficult than to attempt universal vaccination.

One other point in relation to the treatment paralysis, which is very distressing when it occurs—I think it is very important that when this accident does occur, and when it is so unfortunate that it results in death, that an autopsy be secured, if possible, in order to determine if we can the real nature of this treatment paralysis. A boy developed paralysis on the 16th day of treatment. He had been very badly bitten in the face, but treatment was advised, and I saw him on the 5th day of the disease. He died, and an examination of his brain showed that he had meningitis. It was impossible to diagnose the disease during life, and this diagnosis was further complicated as a spinal puncture had been made.

The Administrative Control of Communicable Diseases*

CLARENCE L. SCAMMAN, M. D.

Director, Division of Communicable Diseases, Massachusetts Department of Public Health, Boston, Mass.

THIS is a broad subject. Three official agencies, federal, state and local, are concerned in the administrative control of communicable disease. Although their services overlap, this discussion will be confined more especially to communicable disease control as administered by the small municipal or county health department.

Although we speak of the control of communicable disease, what we really mean is the attempt to control human beings (or animals) already suffering from disease or conditions which if not controlled may lead to their infection.

As our knowledge has increased in regard to the natural history of certain communicable diseases, our methods of control have improved. Because of their varying character, no two communicable diseases can be dealt with by identical methods of administrative control.

Despite this fact, certain general principles can be laid down as essential in any fairly comprehensive attempt toward sound administrative procedure. These of necessity may vary somewhat in detail, depending on particular circumstances.

The health officer of the local unit must have from the medical profession or other sources, prompt notification of the presence of communicable disease, and he in turn should furnish to the profession, directly or indirectly, clinical and laboratory diagnostic aids in order that early diagnosis may be made of suspicious cases. When a case is reported, the executive officer or one of his staff should visit promptly:

1. To isolate the patient either at home or in hospital
2. To quarantine or supervise, as the situation indicates, both immediate and remote contacts
3. To placard the premises and instruct the householder
4. To make such investigations as to the source and mode of infection as the circumstances may warrant, not only that the source of infection may be discovered but that further spread of infection may be stopped
5. To collect the essential epidemiologic data and file them as a permanent record

* Read before the Health Officers Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

In addition, the live health officer will maintain close coöperation not only with the medical profession, but with the school authorities and all unofficial agencies.

If the local health officer functioned as outlined above and reported the case to the central authority, with comment if indicated, his local unit would inevitably receive a relatively high rating from the point of view of efficiency. But such a local unit is extraordinary. The unit that I have peculiarly in mind is ordinary. It has done two things when the case was reported, placarded the premises and mailed a report of the case to the central authority. It will, no doubt, "fumigate" when "the card comes down," a form of worship in terms of burning incense to the false gods of gaseous fumigation still in vogue. You have no doubt heard it said of some kindly, garrulous, old gentleman, who was in his anecdotage, that he was simply "living in the past." It seems that there are a good many small health departments still living in the past.

It is true that fifty years ago "a warning sign" plus fumigation when the case was released from quarantine gave satisfactory evidence, by means of sight and smell, to the interested public that the board of health was functioning perfectly. It is true that antagonism toward boards of health was engendered by the rigidity of quarantine and the show of authority which was part and parcel of our old control procedures. But fifty years ago little or nothing was known about infectious diseases. Although what we still have to learn at times fills us with dismay, the advance in our knowledge of these diseases has been remarkable. We have adapted our administrative procedures somewhat to this newer knowledge. We use coercion less and coöperation more. We depend on medical supervision in the control of contacts and give considerable latitude to proven immunes. Finally, with artificial immunization we are on the way toward the soundest possible method of communicable disease control.

While we must still consider certain factors of control concerned with the environment, especially water supply, sewage disposal, and the supervision of milk and other foods, we are now concerned more with the individual than with his environment. For some years most of us have believed that "sanitary instruction is even more important than sanitary legislation."

The larger and better organized health departments have quietly met the demand for individual instruction in connection with communicable disease control by means of the public health nurse. How have the small local departments met the challenge? A few have, with courage and good judgment, appointed nurses as executives and a few more have met the situation by combining the activities of a school

nurse with those of a communicable disease nurse. The argument against the use of a communicable disease nurse in a small place, except for its greater intensity, is similar to arguments which have been advanced in larger areas, namely, that she may be a carrier of infection. This question was fully discussed in the April, 1926, number of the *JOURNAL* of this Association.' There may still be argument against the utilization of a nursing service in connection with communicable disease control, but it seems to me that those who will continue this argument, will also continue to argue in favor of gaseous fumigation.

The nurse undoubtedly has a definite place in the administrative control of communicable disease. Is there an informed opinion among the householders of your small localities and mine about the actual means of spread of the common communicable diseases of childhood? The need for individual instruction in the few sound methods of communicable disease control is a crying one indeed. As I see it, we need more sense and less nonsense in connection with our efforts to control infection both within and without the household. How many mothers in small places understand the purpose of isolation and quarantine? Do families in your small towns never have secondary cases following a case of typhoid fever in the household? Do the mothers in all your smaller communities know that measles and whooping cough are especially fatal diseases in children under 3 years? Is concurrent disinfection actually carried out in connection with isolation of communicable disease in such places? Finally, are the mothers in this type of locality fully comprehending the value of artificial immunization? The answer to all these questions for the majority of our smaller communities is "No."

The gap between what we know and what we want our citizens to know is tremendous. What an opportunity to "put over" all this individual instruction by means of the public health nurse. At no other time is the mother so responsive to instruction as when one of her family lies ill of some communicable disease. With instructive home visits, it would soon become common knowledge that with a few exceptions communicable diseases are spread by the route that infected body discharges take from the patient or carrier to the susceptible individual. Perhaps a slogan might be developed for such a nursing service which might run like this, "Preaching as she placards," teaching that "people, not things, spread disease."

One constantly hears of the lack of funds in any health department, but the small municipality or county is especially hampered in any attempt to develop even a minimum of health service. A communicable disease nursing service, however, may be developed either as a full-

time, or part-time service in combination with school, tuberculosis, or other community nursing service. With such an arrangement there is possible a maximum of service at minimum expense. Upon this service and its development rests the ultimate success of communicable disease control in the smaller places.

I am by no means concerned with the "glorification" of the public health nurse. Yet the nurse has demonstrated her effectiveness in other phases of public health activity. However important proper training may be, the successful nurse in addition usually has the reputation of accomplishment, plus the peculiar power of making friends not only for herself but for the organization for which she stands. This is of more than passing importance. Health departments as they go have no host of friends among the householders. Too many health departments have forgotten that the householder has a soul and a mind, as well as a body. Fortunately the nurse has the happy faculty of ministering to the souls and minds of the people as well as to their bodies.

Unless the health officer or the board of health is able to reach the individual with information and instruction upon which the citizen may build for himself a course of hygienic conduct in order to escape infection, there must of necessity be futility in our administrative practices in communicable disease control.

CONCLUSIONS

Small municipal or county health departments organized with sound administrative procedures in mind do function efficiently in the control of communicable disease. These, however, are in the minority. The great majority fail to function at all, usually because of the lack of training of the executive officer, his lack of interest and vision, or both.

The use of a public health nurse either as an executive officer, or in the capacity of a communicable disease nurse, full or part time, will furnish a maximum of service at a minimum of expense.

Unless there is informed public opinion in regard to the purpose of our procedures in communicable disease control, superstition and ignorance will be constantly in conflict with scientific enlightenment.

The nurse is peculiarly fitted to carry into the homes the story of how to avoid infection and to interpret to the householder the purpose of isolation, concurrent disinfection, quarantine, and artificial immunization.

Pneumonia Quarantine*

H. J. BENZ, M.D.

*Superintendent, Bureau of Child Welfare, Department of Public Health,
Pittsburgh, Pa.*

THE CONTROL of the morbidity and mortality of pneumonia is a major public health problem. Pneumonia ranks first in the list of acute, communicable diseases as a cause of death.

DEATHS IN 1924

Smallpox	900	Measles	8370
Infantile Paralysis	1128	Whooping Cough	8385
Scarlet Fever	3109	Diphtheria	9756
Typhoid Fever	7212	Pneumonia	108700

Prior to 1924, no concerted effort had been made in preventive medicine to control pneumonia, though the contagiousness of pneumonia seems to have been recognized as early as 1497 by Savonarola of Venice. Dunns in 1592 wrote that peri-pneumonia is a contagious disease, because he observed that it attacked many in the same family. Vaughan¹ states: "All students of epidemiology recognize that the pneumonias are infectious diseases and are disseminated by spitting, sneezing and coughing." Rosenau² states: "Lobar pneumonia is a communicable disease which should be classified with the infectious fevers."

In the year 1923 and early in 1924, many consecutive cases of pneumonia in a household were reported to and investigated by the Pittsburgh Department of Public Health; and during March, 1924, 22 such cases were found in which a direct, intimate contact with a primary case and second or subsequent cases of pneumonia were found by investigators of the health department to be authenticated.

Riesman,³ in discussing pneumonia quarantine, says:

In the past, we have attacked pneumonia from the standpoint of the individual, just as we have attacked—and with about as much success—the common cold. We have looked for medicinal specifics, for prophylactic vaccines, for therapeutic

* Read before the Health Officers Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

NOTE: Owing to the death of Dr. C. J. Vaux, Director, Department of Public Health of the City of Pittsburgh, in April, the presentation of a paper on Pneumonia Quarantine was submitted to me at that time as I had been in his council and worked with him on this subject since its inception in Pittsburgh, and, in presenting this paper I cannot do any greater honor to him than to use his language in many places and beg your indulgence if I do so.

serums, and yet, though all these efforts are deserving of praise, pneumonia is almost as devastating a disease as it was before they were begun. Let us see whether the position that pneumonia should be a quarantinable disease is well taken.

We can get a clearer answer to this question if we consider the reasons in the past that have deterred physicians from considering the disease one that can be influenced by quarantine.

Pneumonia seems in many instances to begin explosively (after a wetting or chilling), suggesting that it is an autogenous and not a heterogenous infection. When, however, we study carefully the history of pneumonia patients, we find that many had a slight, preliminary, neglected cold. This was found to be true by the Philadelphia Pneumonia Commission, and is my personal experience in private and hospital practice. Therefore the hypothesis that the abrupt onset militates against infection from another source is very much open to question.

The second reason that made men doubt the transmissibility of pneumonia is the rarity of contact infection. That point too has lost much of its force. In the first place, contact infection occurs though it may not be frequent. The other day, I was informed of a pathetic instance in one of the seashore towns of New Jersey. A physician fell ill with pneumonia. His son, a student in a New England college, was called home. The father died, and within a few days the son also died of pneumonia. Every practicing physician can recall in his own experience double or triple cases in the same household. Dr. James M. Anders, in his study of pneumonia in Philadelphia, found the highest death rate in the most densely populated parts. Dr. Frederick T. Lord has collected a number of other examples of indubitable contact infection.

We may also answer the objection with regard to contact infection by an analogy. Tuberculosis was looked on until our own time as an hereditary but not a contagious disease. Only after Dr. Flick had published his epoch-making researches on tuberculous houses did the contagiousness of the disease and the fact that tuberculosis in a given individual invariably harks back to some other tuberculous individual, gain general acceptance. And yet, actual contact infection in sanatoriums or hospitals is not common; otherwise, the contagion theory would not have had to fight its way.

The third reason that has delayed the institution of quarantine in pneumonia is the prevailing belief that the pneumococcus is a more or less constant inhabitant of the human mouth. If this were the case, then quarantine could serve no useful purpose. But is it the case? I think bacteriologists are now generally agreed that the pneumococcus found in healthy persons is nearly always a nonvirulent micro-organism or one possessing but slight virulence. The highly virulent types, those responsible for the majority of the cases of pneumonia, are found only in the pneumonic patient or in the occasional carrier, an individual who has either recently recovered from pneumonia or has been in close contact with a pneumonia patient. That is the view of such distinguished authorities as Park and Williams⁴ and of Bigger⁵ and of Dublin. The latter expresses the unequivocal opinion that pneumonia is transmitted usually from a definite case of pneumonia or sometimes from a healthy carrier previously in contact with a pneumonia patient.

One other point of importance should be mentioned, since it has a bearing on the obscure problems of pneumonia transmission. The pneumococcus is a fairly tenacious organism. In sputum attached to clothes and not exposed to direct sunlight, it may retain its virulence as long as 55 days. Direct contact is therefore not

essential, since transmission can be brought about by surviving germs whose presence and source may not be suspected.

Perhaps there is also conveyance through non-human sources, through animals, milk, etc. While little is known about this, it is a point deserving investigation. It should furthermore be remembered that the pneumococcus is responsible for many cases of simple bronchitis, and might gain in virulence in its passage through the bronchitic patient.

When we consider the facts I have mentioned, we cannot help giving our adhesion to the proposal for a modified quarantine in pneumonia. It is a logical procedure, based on those epidemiologic grounds that have guided us toward quarantine in other infectious diseases.

Pneumonia quarantine was inaugurated in Pittsburgh on April 1, 1924, because some method was necessary to cut down the unenviable record we had of being the highest in pneumonia deaths as reported by the Department of Commerce, Washington, D. C., in a report dated January 12, 1924, embracing 72 cities, and giving Pittsburgh a rate of 371 per 100,000. We appreciated all the technical, statistical questions involved in comparative figures, and also had been watching the steady rise of pneumonia in the last ten years. In a preventive way, nothing had been done to reduce this incidence.

Based on the assumption that pneumonia is an infectious disease, a plan to have all pneumonias reportable and to place a quarantine on every case was inaugurated on April 1, 1924, appreciating that no more can be expected from quarantine of pneumonia than from quarantine of any other infection, and that the real value would be in preventing many persons from contracting the disease who otherwise would have been exposed.

The plan of quarantine and isolation was endorsed by the County Medical Societies of Allegheny County.

In Pittsburgh, the regulation covering reports of cases of pneumonia was made all inclusive in order to avoid any loophole for failure to report a case. The regulation follows:

Pneumonias (all forms) are reportable diseases in the City of Pittsburgh; specify (a) lobar pneumonia; (b) broncho pneumonia; (c) pneumonia complicating influenza; (d) pneumonia complicating other communicable diseases; (e) all other pneumonias, as traumatic, anaesthetic, senile, etc.; specify whether lobar pneumonia or broncho pneumonia in all of the above primary conditions.

Actual quarantine in certain types of cases is optional with the Department of Public Health; also, the quarantine regulation is a modified quarantine, as follows:

Modified quarantine will be enforced in all cases of pneumonia, except that under the classification "e" ("all other pneumonias, as traumatic, anaesthetic, senile, etc.") which may be quarantined, at the option of the Department of Public Health. This modified quarantine will consist of placarding, isolation of the patient,

prohibition of all visitors, but no restrictions on other members of the household, including school children, provided isolation is complete and instructions from the Department of Public Health are properly carried out. No minimum number of quarantine days specified, the quarantine period being until recovery or death of patient.

Complete sanitary cleaning of the premises is required before release, but, when this is accomplished thoroughly following the physician's report of recovery, quarantine release is made at once. In a fatal case, after sanitary cleaning, no funeral restrictions are made. Regulations governing pneumococcus carriers or laboratory release regulations were not incorporated. This may be a desirable later step, but at present, because of the apparently beneficial effect in reducing the number of cases and deaths from pneumonia and the complete approval accorded the regulation by the physicians, hospitals and citizens of Pittsburgh, the present pneumonia quarantine regulations have been satisfactory and will continue indefinitely.

When this plan went into effect, in every case reported from a private home, a Department of Public Health nurse made an investigation of the patient: age, sex, color, nativity, occupation, living conditions, contacts in house, and a history as to precedent exposure to a case of pneumonia, bronchitis, influenza and cold, and whether or not the present pneumonia was subsequent (in five days) to a prior cold or illness of the patient.

In 5277 cases so investigated, it was found that 3808 or 72 per cent gave a history of preceding "cold" or grippe, so-called. No causes were included where the attending physician made a diagnosis of influenza as the primary disease.

The reaction of the public laity and the medical fraternity to this pneumonia regulation has been a pleasing factor. At no time did we have anything but the wholehearted, earnest support of both to this work. This first step—reporting and quarantine—is a valuable aid in pneumonia prevention and has stimulated the second step in prevention—that of arousing public interest by making the public cognizant of the danger of pneumonia and reasons for regulations and results obtained. There has been no single complaint regarding pneumonia quarantine regulations by lay citizens or physicians; on the contrary, many commendatory letters have been received from hospitals, physicians, lay public and civic organizations, all indicating endorsement of the plan and willingness to coöperate.

In the summary appended, showing cases and deaths since 1923 by months, it will be noted that prior to the establishment of our reporting and quarantine regulations the number of pneumonia deaths was in

excess of the number of pneumonias reported, and that since April 1, 1924, the contrary is true. The pneumonia incidence shows a decided drop and is so reflected by the deaths, taken year by year or by months of each year; and, while it is too early to pass conclusions definitely, from all indications, pneumonia quarantine has had some material effect in reducing the incidence in Pittsburgh.

There are many infectious, environmental, personal and climatic factors regarding the epidemiology of pneumonia which are worthy of intensive investigation and study. There is the purely medical question, with laboratory investigation, typing of cases and contacts, and the finding of the relationship of "common cold," grippe, fatigue, etc., to pneumonia.

The other aspect is of an engineering or industrial type, and has to do with heating, ventilation, living quarters, transportation, working conditions, climatic factors, fog, smoke and air pollution. The fact that the percentage of pneumonia deaths in cities is about 50 per cent greater than in rural districts may be due to greater contact or to some of the above factors.

CASES AND DEATHS—PNEUMONIAS (ALL FORMS)
PITTSBURGH, PA.

		1924	1925	1926	1927

	Deaths	2074	1688	1255	737

Having the first two steps—reporting and quarantine, and rousing public interest—the third step should be organized study in centers of population as to all the factors in causation and control of pneumonia by a pneumonia commission with funds sufficient for a study over years and collaboration with similar commissions in other centers. Such a commission has been advocated in Pittsburgh, and we are in hopes that it soon will materialize and carry out the project so ably and fearlessly inaugurated by the pioneer in pneumonia quarantine, Dr. C. J. Vaux.

Infant Mortality and Infant Welfare in Prussia

ACCORDING to an official report, the birth rate in Prussia in 1926 was 19.6 per 1,000 population, whereas in 1925 it was 20.9. The infant mortality rate in 1926 was 101 per 1,000 live births, whereas in 1925 it was 104. Infant mortality, which has been decreasing for some time, reached in 1926 the lowest level ever observed. This decrease is attributed not only to the decrease in the birth rate, but mainly to the more extensive welfare work and education of the people in infant hygiene.

Breast feeding, which has become quite prevalent since the war, is being encouraged by payment of nursing benefits by the government.

Infant health was reported to be good in most provinces. Of the approximately 15,000 infants examined in 1926 at health centers in a number of cities, 14.1 per cent were found underfed; in 1925 the percentage was 15.6, and in 1924 it was 25.

A further decrease in the number of cases of rickets was noted and severe forms were rare. Among the infants examined in 58 cities and rural districts in Prussia, 10 per cent were found to have rickets in 1926; 20 per cent in 1925, and 23 per cent in 1924.

The shortage of clothing was found to be less prevalent than in the previous year.

The number of infant health centers rose from 2,847 in 1925 to 3,115 in 1926. Infant welfare work by the municipalities and private agencies included distribution of literature on infant care and of milk, cod liver oil and similar articles. In addition, babies' outfits were loaned to needy mothers, and premiums were given for regular attendance at health centers.—*Volkswohlfahrt*, Berlin, Feb. 1, 1928, vol. 148.

Resistance to Pneumococcus Infection as Influenced by Breathing of Gas Combustion Products*

EMERY R. HAYHURST, M. D., PH. D., FELLOW A. P. H. A.

Professor of Hygiene, Ohio State University, Columbus, O.

IN the symposium on acute respiratory diseases held at the Cleveland meeting of the American Public Health Association, October 17, 1922, Vaughan and Palmer¹ divided the pneumonias into three types, viz., *epidemic*, *sequel* or secondary, and endemic or *seasonal*. They also showed that the seasonal form has a distinct cycle with, for instance, 43 per cent occurring in the first three months of the year, 24 in the second three months, 10 in the third three months, and 23 in the last three months; also that this ratio is maintained, with slight modification only, year after year. These authors likewise presented statistics to show that the behavior of pneumonia is peculiar in that cities suffer fully a third more than country districts, but that there is a vast difference in cities—a city like Pittsburgh having a ratio of 275 as against 140 for Cleveland, while 16 per cent of the deaths in Pittsburgh were attributed to pneumonia as against only 8 per cent in San Francisco. In the 25-year period from 1864 to 1888 the combined rates for several large cities in the country showed a mortality of 189, or 7 per cent of total deaths, but in the next 25 years this rate was 232, or 12 per cent of total deaths in these cities. It will be seen from the above that there is good statistical evidence pointing to atmospheric pollution by combustion products as a possible explanation for increased pneumonia death rates under certain conditions.

In 1922 Oppenheimer and Spaeth² reported the practical success of a method for determining susceptibility to one of the forms of pneumonia by the injection of a culture of Type I pneumococcus obtained from the diagnostic laboratory of the New York State Board of Health, which could be so controlled that the minimum lethal dose could be determined. Their method was to make intraperitoneal injections of salt solution suspensions of the culture. By the use of this method they

* Read before the Industrial Hygiene Section of the American Public Health Association, at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

announced that fatigued white and hooded rats were less susceptible to pneumococcus infection than non-fatigued rats.

Later in the same year Spaeth¹ reported similar findings for guinea pigs. Incidentally, Spaeth also found that pneumococcus grew as well in the blood from fatigued animals as in the blood of control animals, showing that the protective factor apparently produced by fatigue was not in the blood itself. Later in the same year Nicholls and Spaeth² reported other experiments with like conclusions, "that fatigue definitely increases the resistance of these animals (guinea pigs) to lethal injection of Type I pneumococcus."

In 1925, the year in which Spaeth³ lost his life while collecting material in the Siamese jungle, where he contracted an infection, he further reported as a result of the same method of investigation that good physical condition appears not to include the resistance to infection and that young starved guinea pigs and exhausted pigs resist infection better than do normally fed control pigs because of the weight recovery process or increased anabolic rate, and that the factor concerned was not fatigue nor fatigue products but "that natural resistance is a function of anabolic rate."

It has been our purpose to apply the method of Spaeth and coworkers to determine the resistance to pneumonia in the matter of breathing combustion products, as from chimneys, poorly ventilated furnaces, unflued gas stoves within the home, etc.

To our knowledge no experimental evidence has yet been offered showing a disturbance in natural resistance to pneumonia under these circumstances. While, as stated above, vital statistics plainly point to such a relationship, direct evidence is apparently lacking. Our investigation has, therefore, been an attempt to supply some direct evidence. In truth, it is barely possible that such exposures may increase the resistance to pneumococcic infection by increasing the anabolic rate, such as Spaeth found in connection with fatigue and with starvation. Our investigations have been open to either finding.

ARRANGEMENTS

On March 29, 1926, we were awarded Grant 87, \$500.00, by the Committee on Scientific Research of the American Medical Association "to determine by the experimental method, using lower animals, the effect of breathing combustion products of ordinary carbonaceous fuels (e.g., coal, oil, gas) upon the susceptibility to pneumonia, using a known dosage of a known type of pneumococcus for inoculation into exposed and controlled animals."

The research was undertaken with the coöperation of the Depart-

ment of Bacteriology (in charge of Dr. George B. Morrey), the Department of Metallurgy (in charge of Prof. Dana J. Demorest), and the Department of Public Health (in charge of the writer)—all departments of the Ohio State University; and after July 1, 1927, with the added assistance of the Division of Laboratories of the Ohio State Department of Health.*

The investigation got under way June 17, 1926, and continued to October 28, 1927, with equipment set up first in a ground floor laboratory of Lord Hall, and after July 1, 1927, because of building alterations, removed to the State Laboratories, also on the Campus.

METHODS, SCOPE AND COMMENTS

Small batches of white rats—4 to 19 in number in various runs—were housed in a tight box, partly glassed and having openings for inlet and outlet ventilation which could be controlled. The rats lived day and night in an atmosphere surcharged with the completely oxidized combustion products emitted from a large gas burner of the Bunsen type, which stood on the laboratory floor. Natural gas, containing no carbon monoxide, was used. An average composition of this gas analyzes as follows (Burrell)⁶:

<i>Gas</i>	<i>Per Cent</i>
Carbon dioxide (CO ₂)	Trace
Methane (CH ₄)	84.7
Ethane (C ₂ H ₆)	9.4
Propane (C ₃ H ₈)	3.0
Butane, etc. (C ₄ H ₁₀)	1.3
Nitrogen (N ₂)	1.6

The products of this burner, mixed with controlled proportions of air, were collected in a superimposed funnel connected to a 3 inch iron pipe. This pipe which was several feet in length was cooled by a stream of tap water constantly running over it. This pipe entered a sub-compartment of the exposure box, whence the gases passed up through small openings in the floor of the exposure box. A continuously recording thermometer and a hydrometer were placed in the box where their readings were visible from the outside; also a room thermometer, on the box. Control animals were simply kept in the usual wire cages in the same laboratory. Temperatures in the exposure box were kept as comparable to the general room temperature (ranging from 53° to 88° F.) as possible. Control animals were not confined in a closed box which would not have paralleled the exposure box in which the ventila-

* Those who participated in the research directly, though at different periods as a rule, were George W. Bond, instructor in bacteriology; Andrew J. Kardos, graduate student in bacteriology; Dr. R. F. Jukes, instructor in bacteriology; Leo Eye, chief bacteriologist, State Laboratories; Fred Berry, Director of State Laboratories, and K. K. Koontz, metallurgist with Prof. D. J. Demorest.

tion was positive and fairly active. All cages were cleaned once daily when the lid on the exposure box was opened and the atmospheric condition temporarily disturbed. Abundant food was supplied to both groups.

Analyses of the products were made for carbon dioxide, oxygen, and carbon monoxide, although it was the intention to keep carbon monoxide absent. Various atmospheric compositions were easily maintained as desired, although on two or three occasions in the early months of the investigation monoxide was produced and promptly killed the rats under exposure.

It was first necessary to feel out the tolerance of the rats, using both sexes, and medium to large sized animals. This was done by gradually increasing the percentages and lengthening the periods of exposure to the combustion products indicated. This part of the investigation occupied the first 10½ months, or until April 30, 1927. It is to be noted that Hermans' demonstrated that an atmosphere containing 15 per cent of oxygen and 2 to 4 per cent of carbon dioxide is not toxic. Such would especially apply to burrow animals like the rat.

After having sensed out the tolerance to various concentrations with both high and low temperatures, and over many days of exposure,

animals were inoculated intraperitoneally with a strain of the same Type I pneumococcus (obtained from the New York State Laboratory) as was used by Spaeth and his coworkers, above referred to. Our bacteriologists found the m.l.d. of this strain difficult to control or rather to maintain when once found, so that there was constant danger of killing all the rats—both exposed and control—or of killing none in any given inoculation series.

Space does not permit of the inclusion of the protocols and other data of the various runs and inoculation experiments, but copies of same are available to those interested. In all, 7 tolerance experiments varying from 21 to 111 days and 3 inoculation experiments were made. A typical example of a tolerance experiment is given herewith:

EXP. H.—*Tolerance experiment (similar to Exp. C)* followed by third inoculation experiment*

This experiment got under way with new and improved equipment July 9, 1927, the plan being to run an exposure of at least 100 days under the same general conditions as the two preceding experiments (F and G). A batch of 19 young adult white rats was put into the exposure box. The controls consisted of 8 similarly aged normal rats.

TABLE I

TOLERANCE EXPERIMENT (SIMILAR TO EXP. C)* FOR 111 DAYS.

Dates	No. of Days	No. of Rats	CO ₂ Per cent	O ₂ Per cent	Temperature Range	Remarks
{ July 9	111	Exposed:	3.4	13.8	{a} Exposed: 53°-88° F. Control: room summer temperature	3 rats died in first 2 days. These were replaced on 4th day
{ Oct. 28		19	to	to		
		Control: 8	4.0	15.1		
July 18						Litter of young born in exposure cage
July 20						Young rats apparently eaten by others in cage
July 27	18					1 exposed rat died
Aug. 8	30					2 exposed rats died
Sept. 10	63					1 exposed rat died
Sept. 15	68					1 control rat died
Oct. 1-24	83-107					4 exposed rats died
Oct. 28	111					11 exposed rats remain 7 control rats remain

* Determining tolerance under markedly abnormal atmospheric conditions but within room temperature ranges.

On post-mortem none of the rats showed evidences of pneumococcus infection. The lungs were apparently normal. The cause of death was undetermined.

Comment—It will thus be seen that 8 of the 19 rats placed in the exposure box died during the period of 111 days, during which time only one of the 8 control rats died.

INOCULATION EXPERIMENTS

EXP. F. *First inoculation experiment* (April 30, 1927)

Here the 4 long-exposed rats (61 to 175 days), the 3 other exposed rats (26 days), and the 7 control rats remaining (mentioned in Exp. E), were inoculated by intraperitoneal injections, using 50,000 pneumococci per gram of body weight.

Results:

Six out of the seven exposed rats died within 48 hours of the time of inoculation. Of the control rats, one died out of the seven inoculated.

A further pair of control rats was inoculated at the same time, using twice the dosage of pneumococci. Both of these rats died within 24 hours, showing the potency of the suspension used.

All the dead rats were examined at autopsy and cultures from the heart's blood taken. The cause of death in each case was septicemia and peritonitis; lungs crepitant throughout and the separate lobes floated freely on water.

Second inoculation experiment (May 26, 1927)

The same strain of Type I pneumococcus used in previous experiments was injected by the intraperitoneal route. This strain was, however, of a lower virulence and was found by tests to require a heavy dosage to kill, which it did ordinarily in 48 to 72 hours instead of within 24 hours. This was considered an advantage. One c.c. of standardized suspension in salt solution was injected per 100 grams of body weight:

One rat only of the exposed group died; this was on the second day.

One rat only of the control group died; this was on the third day.

On autopsy, pneumococcus was isolated in pure culture from the heart's blood in each case. No gross evidence of pneumonia.

None of the remaining inoculated rats in either the exposed or control groups died. They were alive and in good condition on the sixth day.

Comment—From this experiment it can only be concluded that, in the face of preliminary virulence tests, lethal doses were not used. Also it is possible that there was no material difference in susceptibility in either of the groups because the period of exposure for the test group—21 days—may have been too short. Possibly both factors were operative. At all events, the results were unsatisfactory from any point of view. The experiment, however, shows the difficulty encountered on the bacteriological side of the question in developing a just-sub-lethal dose for normal rats.

Third inoculation experiment

The 11 exposed rats remaining and the 7 regular control rats, to which 4 new rats were added to bring the controls up to 11 rats for inoculation purposes, were inoculated on the afternoon of October 28, 1927, and the animals returned to their respective quarters. In order to be certain that no changes of a lethal character might supervene in the gaseous exposure mixture and thus inadvertently kill off the inoculated exposed rats, a second cage of 6 normal rats was also placed in the exposure box. These 6 rats remained in good condition up to the time the last test rat was taken out, i.e., 89 hours following the inoculation.

The same strain of Type I pneumococcus used in the previous experiments was

again employed. Preliminary tests through several series of rats showed that the strain had increased in virulence since the last inoculation experiment, May 26, 1927—156 days prior. Following Spaeth's method of a definite routine in the animal passage, incubation of the freshly isolated culture, storage of this culture in the icebox, and preparation of a new culture for injection, both saline and broth suspension were obtained such that 0.001 c.c. per gram weight killed one out of three rats in each test experiment.* As the result of numerous preliminary tests, it was felt this was as near the desired result as could be obtained. Therefore, 0.001 c.c. per gram weight of animal of the saline suspension was utilized for the final test series.† Injections were made intraperitoneally as before. The results of the inoculations are shown in Table II:

TABLE II

THIRD INOCULATION EXPERIMENT

<i>Time following inoculation</i>	<i>Exposed rats</i>	<i>Control rats</i>
21 hours	2 died	
27 hours	1 died	
34 hours		1 died
40 hours	3 died	
42 hours		1 died
48 hours	1 died	
55 hours		1 died
70 hours		1 died
72 hours	3 died	
76 hours		1 died
82 hours		1 died
89 hours	1 died (the last one)	
100 hours		1 died
5 days		1 died
7 days		1 died
8 days		1 died
26 days		1 still alive
	<hr/>	<hr/>
	Total 11 rats	11 rats
		Median time of death—40 hours.
		91 hours.

Of the *exposed* rats, 5 were males, 6 were females. Their average weight before injection was 185 grams; average weight after death 167.4 grams. These rats showed a steady decline in physical conditions in each case following the inoculations until death occurred.

Of the *control* rats, 6 were males, 5 were females. Their average weight before injection was 200 grams; average weight after death of 10, plus the one rat which remained alive, was 182 grams. The first 3 of these rats to die showed a steady decline following inoculations until death occurred. With the remaining 8 rats, a distinct rallying period occurred after about the 60th hour. They began to eat and to move around, so that recovery seemed imminent. However, they later slumped, except one which survived throughout, and died at the hours or days stated (see Table II).

Upon post-mortem, 5 of the 11 exposed rats, and 2 of the 11 control rats showed a distinct purulent broncho-pneumonia, although the lung tissues floated in water

* In the case of the saline suspension, the rat showed signs of physical decline on the third day and died in 5½ days. With the broth suspension, the rat died on the third day.

† The standardized saline suspension contained 5 billion pneumococci per c. c.

in all cases. Smears made from the heart's blood showed abundant pneumococci in all cases.

Comment—From this experiment it will be seen that:

1. Eight out of the 19 exposed rats died during the period of 111 days' exposure to the combustion products of the Bunsen burner (as described), whereas only 1 out of 8 control rats died during this period. Post-mortems failed to explain this increased tendency to die, but pneumonia was not the cause.

2. Ten of the exposed rats which were also inoculated with the standardized dose of Type I pneumococcus died within 72 hours, as against only 4 of the control rats similarly inoculated; also the latter showed a tendency to recover provided they lived after 60-70 hours, and 5 survived for 5 or more days. It is evident also that despite the preliminary tests for virulence of the saline suspension used, the dosage was ultimately lethal to the normal (control) rats.

SUMMARY OF INVESTIGATIONS

1. Through the cooperation of a number of scientific agencies an investigation was made to determine the susceptibility to pneumonia on the part of white rats as influenced by the breathing of completely oxidized combustion products from a carbonaceous fuel, viz., fumes from a Bunsen burner using natural gas (which contains no carbon monoxide). The conditions simulated the breathing of burned gas fumes in a room having an unventilated gas stove.

2. The intricacies of investigative work were bacteriological and metallurgical, and credit for same should be given to those named rather than to the writer.

3. Experiments to determine the tolerance to increasing amounts of the combustion products in question were started June 17, 1926, and continued to October 28, 1927. Here it was found that, where room temperatures prevailed (50° - 88° F.), the experimental animal—the common laboratory white rat—is fairly tolerant for upward of 100 days and more to an atmosphere containing $3\frac{1}{2}$ -4 per cent carbon dioxide, 14-15 per cent oxygen, water vapor to saturation, and, in one experiment, to the addition of pulverized coal dust to the above for 35 days. With lowered temperatures (41° - 68° F.) broncho-pneumonia appears to supervene readily.

4. In a collateral investigation it was possible to isolate a strain of Type I pneumococcus of fairly controllable dosage and to use this in three inoculation tests of white rats previously exposed for varying periods of time, viz., 90 days, 21 days, and 111 days, respectively, to the concentrations of combustion products indicated above. In this, our bacteriologists followed in general the method devised by Spaeth and coworkers of Johns Hopkins University in their studies of fatigue and starvation as related to pneumococcus infections. However, this difference in results occurred: where Spaeth reports lobar pneumonia, even with a critical period, following peritoneal injections, we found only occasionally purulent broncho-pneumonia, but chiefly septicemia (pneumococcemia) and peritonitis. However, death was due to pneumococcic infection.

5. The inoculation of our first experimental rats which had been exposed for periods varying from 26 to 175 days resulted in the death of 6 out of the 7 exposed, whereas control rats given similar dosages had but 1 death out of 7. A second experiment in which the rats were exposed for only 21 days resulted in indefinite findings since but 1 rat out of each group of 7 succumbed to the infection pointing to a sublethal dosage. A third experiment extending for 111 days and using an initial batch of 19 rats in the exposed group had 8 of the rats die during the period of exposure while but one of the control group of 8 rats died during the same period.

Furthermore, after inoculation of an unintentionally too virulent dose the remaining 11 exposed rats died between 21 and 89 hours (median 40 hours), without any signs of rallying at any time, whereas 10 of the 11 control rats died between 34 hours and 8 days (median 91 hours), several tended to recover, and 1 survived.

CONCLUSIONS

While we have direct evidence that rats are surprisingly tolerant of the prolonged breathing of completely oxidized fuel combustion products (as from an unventilated gas stove) rich in CO_2 and O_2 , etc., upwards of one-third of them die from undetermined causes during a period of exposure varying from a few to 111 days. Furthermore, upon inoculation of the remaining exposed rats with a standardized suspension of Type I pneumococcus, they succumb much more readily than do control animals, pointing to a lowered resistance as the result of such exposure. However, more experiments are needed to warrant definite conclusions.

Warring Against Trachoma in Argentina

THE Argentine Red Cross is undertaking an active campaign against trachoma. A model dispensary for the treatment of trachoma in its early stages will be established in every school, and a body of Red Cross nurses who are specialists in the treatment of infections of the eye, coöperating with the national department of health, will examine the school children, visit them in their homes, demonstrate methods of prevention, report new cases discovered, and arrange for their examination and treatment. Lectures on diseases of the eye and their prevention will also be given for teachers and the general public.

Program and Preliminary Results of the Committee on the Grading of Nursing Schools*

C.-E. A. WINSLOW, DR. P. H., FELLOW A. P. H. A.

Professor of Public Health, Yale School of Medicine, New Haven, Conn.

THE HISTORY of nursing education shows that progress in this field has generally come as a direct response to unusual services, rendered to an individual or to the community, by a nurse or group of nurses. It is natural and inevitable that society should wish to provide facilities for the training of a class, the value of whose service has been recently and clearly demonstrated. The most important single event in the chronicles of nursing education, the foundation of the training school at St. Thomas's in London, expressed the gratitude of the British people for the revolution wrought by Florence Nightingale; and throughout the land there is many a school which owes its strength to the appreciation by some influential individual patient of the skill and devotion of some individual nurse.

To the members of the Public Health Nursing Section of the American Public Health Association it must be a peculiar source of gratification to recall that the remarkable advances in nursing education which have been made during the past 5 years owe their inception in peculiar measure to a realization of the unique public service rendered by the public health nurse. It was the Committee on Nursing Education, supported by the Rockefeller Foundation, which took the first step in this recent forward movement; and this committee was originally constituted with an increase in quantity and quality of public health nursing as its primary objective.

I have called the report of this committee, and that of its executive officer, Josephine Goldmark, R. N., the first step in our recent campaign for the improvement of nursing education, and I believe this to be the case. For the first time in the history of nursing, a joint committee, including some of the most eminent physicians of the country, adopted without a dissenting voice a report in which, among others, the conclu-

* Read before the Public Health Nursing Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

sions were drawn: that, while the use of a less qualified attendant might be justifiable and advisable in certain types of chronic illness and convalescence, the care of acute and serious illness and the teaching of hygiene to the individual in the home can only be safely carried on by a person of high educational qualifications; that the education given in the average hospital training school is often inadequate and irregular and unrewarding; and that this condition can only be remedied by providing funds for nursing education and direction of nursing education which will insure the pursuit of an educational aim—undeflected by demands of hospital administration which may run counter to such an aim. The committee report placed this fundamental issue clearly, and frankly, and with weight of medical and nursing authority, before the public. It led directly to the independent University Schools of Nursing at Yale and Western Reserve and it laid the basis, indirectly, for a general effort to improve the status of the education of the nurse.

The Committee on the Grading of Nursing Schools is, from a purely logical standpoint, the natural next step in such a program of advancement. Historically, however, its origin was a wholly different one and it is constituted in a very different fashion from the Committee on Nursing Education and is bound by none of the implications of the work of the earlier body. The present study was organized as a result of the appointment by the American Medical Association of a committee to confer with representatives of the League of Nursing Education, which had long been working on the problem, and to devise a combined method of attack. After preliminary conference, the Committee on the Grading of Nursing Schools was organized as a formal body, primarily made up of official delegates from the 7 national organizations interested in the problem as follows:

The National League of Nursing Education, Elizabeth C. Burgess, R. N., and Laura R. Logan, R. N.

The American Nurses Association, Helen Wood, R. N., and Susan Francis, R. N.

The National Organization for Public Health Nursing, Katharine Tucker, R. N., and Gertrude E. Hodgman, R. N.

The American Medical Association, William Darrach, M. D., with Winford H. Smith, M. D., as alternate.

The American College of Surgeons, M. T. MacEachern, M. D., with Allan Craig, M. D., as alternate.

The American Hospital Association, Joseph B. Haviland, M. D., with William H. Walsh, M. D., as alternate.

The American Public Health Association, C.-E. A. Winslow, Dr. P. H., with Lee K. Frankel, Ph.D., as alternate.

In addition, 6 members at large have been added to the committee, Mrs. Chester C. Bolton, representing the viewpoint of the patient and the hospital trustee; S. P. Capen, W. W. Charters, E. A. Fitzpatrick,

M. D., and Henry Suzzallo, representing the viewpoint of the educator; and Nathan B. VanEtten, M. D., representing the viewpoint of the medical practitioner. The committee was extraordinarily fortunate in persuading William Darrach, M. D., Dean of the College of Physicians and Surgeons of Columbia and the A. M. A. representative on the committee, to serve as its chairman, and Dr. Darrach has thrown himself into the direction of the work of the committee with a vision and an enthusiasm which go far to insure the success of its work. Dr. May Ayres Burgess, a statistician and investigator of unusual experience, was appointed Director, and on her recommendation the committee adopted, November 18, 1926, a 5-year program for the studies which it contemplates. It was felt that these studies must cover a much wider field than that included within the four walls of the training school itself. If the grading of an educational institution is to be worth while, it must be based on very serious consideration of the purposes which such an institution should subserve. In our specific instance, any attempt at educational improvement must take into account the community need for nursing service in respect to quantity, quality and cost; for it is the real needs of the community that must ultimately govern the educational policies to be pursued.

THREE MAJOR PROJECTS

We have therefore included in our program three major projects or studies concerned respectively with:

- Supply and demand for nursing service
- Job analysis of nursing and nurse teaching
- Actual grading of nursing schools

In other words, we want to find out first how many and what kind of nurses are now available, and at what cost, and how many and what kind of nurses should be available in order to meet vital community needs; and what kind of training these nurses should have and how that training should be given. These are large questions and we do not expect to answer any of them with finality. We do hope, however, to obtain a sufficient basis of information along these two lines to make an intelligent approach to the final problem of grading a reasonable possibility.

We plan to distribute the work on these projects in overlapping fashion over the 5-year period, completing the major part of the supply and demand study during the first 2 years, concentrating chiefly on job analysis during the second and fourth years and making progress on the grading plan each year, with special concentration upon it during the fifth year.

We estimate the cost of the supply and demand study at \$42,000,

the job analysis at \$72,000 and the work on the grading plan at \$86,000, a total of \$200,000 for the entire 5-year program. A considerable part of this budget is assured by annual contributions from the 7 parent organizations and the rest will, we feel sure, be contributed by foundations and individuals now having the matter under consideration.

SUPPLY AND DEMAND

The study of supply and demand, was the first objective to be actively attacked and during the first year of the committee's life it has been pushed forward with substantial results. We desired to find out what shortage of nursing service, if any, existed and under what conditions it manifested itself and what particular kinds and qualities of nursing service were concerned. On the one hand, it is a matter of common experience that many physicians complain of inability to obtain the type of nursing service which they need and that the public groans audibly over the cost of the nursing service which it obtains. On the other hand, Janet M. Geister, R. N., pointed out two years ago at the American Health Congress at Atlantic City* that the private duty nurse has her just ground for complaints in regard to unreasonably long hours, inadequate income and irregularity of employment. What are the facts and what is the remedy for a situation, which at times seems to be equally unsatisfactory to all parties concerned?

In order to throw some light upon these questions we attempted a very extensive study by means of questionnaires, addressed to the various parties at interest in the case, in 10 states, selected as reasonably typical of conditions in various geographical sections of the United States. The states finally chosen were California, Georgia, Illinois, Kansas, Louisiana, Massachusetts, New York, Pennsylvania, Washington and Wyoming and in these states we canvassed 5 different classes of persons: the nurses themselves, the physicians, the hospital administrators and the health officers who employ them, and a selected group of the patients who had recently received the ministrations of a nurse in hospital or home. The response to this questionnaire has been extraordinarily encouraging. Thus we have received 30,000 returns from private duty, public health and institutional nurses, with 1,456 returns from physicians and 1,209 from patients; and the results are of substantial interest and significance.

First of all, we have no evidence of a general gross shortage of nurses in any of the regions studied. On the contrary, the testimony of the physicians is almost unanimous that the general supply is ample. There

* Geister, Janet M. Hearsay and Facts in Private Duty. *Am. J. Nurs.*, 26, 7:515 (July), 1926. (Delivered before the American Nurses' Association at the American Health Congress, Atlantic City, N. J., May 18, 1926.)

is a very real and a very serious shortage of specially qualified nurses, of nurses able to do public health work, of nurses able to care for mental cases, or children's diseases; but this is a problem of quality not quantity. There is a real and severe shortage of nurses of any kind at certain times and in certain places, on Sundays and holidays and in rural districts; but this is a problem of organization. There is often a shortage of nurses to care for disagreeable and dangerous cases, individual nurses refusing to care for pneumonia or acute contagious disease or genitourinary conditions; but this too is a problem to be solved only by the development of some type of formal or informal group responsibility. That there is no fundamental and general shortage, is made clear by the fact that our average private duty nurse, during the month of March when the demand for nurses is at its annual peak, spent one day out of seven in waiting for a call.

Nor does it appear that the physicians canvassed have any fundamental criticism to make of the general quality of the nursing service which their patients actually receive. We asked each medical recipient of our questionnaire to describe one typical case in which he had a nurse working under him during the last week in March and whether he would like to have the same nurse again on a similar case. Eighty-seven per cent of the physicians answered "yes." In response to a question as to the necessity of certain special qualifications on the part of the nurse in the typical case cited, the physicians made the following highly significant response.

PHYSICIANS' REPLIES REGARDING SPECIAL QUALIFICATIONS	
Quality or Type of Service	Percentage of cases in which quality was needed
Skill in giving general care and making patient comfortable	63
Skill in observing and reporting symptoms	44
Care in following medical orders	40
Good breeding and attractive personality	34
Skill in handling people	30
Familiarity with hospital routine	28
Skill in asepsis	26
Experience and background	24
Skill in giving special treatments	21
Familiarity with physician's personal methods	20
Familiarity with particular disease	16
Ability to work under heavy strain	13
Responsible adult to take charge of family	3
Mother's helper and house worker	2

Certainly, the first three and the fifth qualifications would seem to indicate the need for a fairly high type of education, in preparation for a profession in which they are to be displayed.

In general, then, I may summarize the picture presented by the reports of physicians and patients somewhat as follows—but please re-

member that in this and all other summaries and conclusions I speak only for myself as an individual, not for Dr. Darrach or Mrs. Burgess or for the committee as a whole. The conclusion would seem justified that there are enough nurses and perhaps too many nurses in the country as a whole (as evidenced by a day a week of enforced idleness even in the month of March); but that nurses are hard to obtain in rural districts and on holidays, that they are often loath to undertake dangerous and difficult cases, and that they are often not qualified for the higher types of nursing service desired. Furthermore, the cost of private duty nursing service ranging from \$35 to \$112, depending on type of illness and location, is unquestionably a very severe burden on the average family.

Next, what has the nurse to say about the problem? Here, our questionnaires give us a very clear answer, but one whose tenor differs markedly according to the particular type of nursing service with which we deal. It is estimated that there are some 110,000 private duty nurses in the United States, 12,000 public health nurses, and 30,000 institutional nurses. The representatives of the first of these groups responding to our questionnaire give us on the whole a rather dismal picture of this sector of the field. They find the burden of 24-hour duty (prevailing in 56 per cent of our cases) unbearably heavy, an undue tax on their physical strength, and an almost insuperable bar to normal human relationships. During one week in March the average private duty nurse lost 0.35 days on account of illness, the public health nurse 0.13 days, the institutional nurse 0.09 days. The general distribution of time for the week is indicated:

TABLE I
DISTRIBUTION OF TIME LAST WEEK OF MARCH

	Private Duty Nurse Days	Public Health Nurse Days	Institutional Nurse Days
Work	5.1	5.7	5.9
Rest	0.5	1.2	1.0
Waiting	1.0		
Illness	0.4	0.1	0.1
Total	7.0	7.0	7.0

In Dr. Burgess's words, the private duty nurse worked less and rested less; but worried more and was sick more.

The second point, also brought out by Table I is irregularity of employment; and it is this irregularity of employment which in large part accounts for the fact that while private duty nursing is costly for the patient it is also unremunerative for the nurse. The main facts in this regard are brought out in Table II.

The private duty nurses begin work at about \$1300 a year and with

TABLE II
ECONOMIC STATUS

	Private Duty Nurse	Public Health Nurse	Institutional Nurse ¹
Average annual income	1311	1720	2079
Per cent reporting savings of over \$1000	28	32	45
Per cent having had to borrow money during past year	14	8	3

1. \$500 a year estimated as value of maintenance

occasional variation between \$1300 and \$1500 keep at about the same level throughout their working lives. The public health nurses start at about \$1450 and rise to a maximum of \$2300 after 25 to 30 years of service. The institutional nurses start at \$1700 and rise to a maximum of \$2500 after 15 years of service.

The private duty nurse on the whole is either overworked or idle; with the net result that her income and her savings are small and her debts large; and, what is perhaps most serious of all, she has no future, nothing to look forward to, for her income and her general status are worse rather than better after 25 years of service than in the year after her graduation. It is no wonder then that but 55 per cent of the private duty nurses canvassed announced their intention of continuing in the work, against 86 per cent of public health nurses and 82 per cent of institutional nurses. You see that your kind of nursing—our kind of nursing if you will let me call it such—is somewhat less profitable financially than institutional nursing but yet seems to yield an even higher satisfaction.

Here, are the sorts of things the public health nurses report on the back of their questionnaires:

I am doing school nursing and am very happy in it. It exceeds by far any other kind of nursing I have done. There is time enough outside of my work so that I can have other interests, and in that way life does not become monotonous and I can have friends which I found impossible to do when I was doing private nursing. My health is very much better as my hours are regular. I can get the proper amount of sleep uninterrupted and I am out of doors part of the time since I make home calls. My daily associates are very agreeable since I come in contact with teachers who serve as mental stimulus. In general, life seems very much worth living.

In my position as county tuberculosis nurse which includes school nursing I guess I feel the thrill of covering the whole county and sort of mothering the whole county, whereas before my efforts were usually confined to one patient at a time. The interest in public health nursing is so far-reaching, and has so many angles that it surely holds your interest and never lets that interest wane.

Public Health Nursing will be my life work; only I hope to be able to take the course at the university and be more competent. I like it better than anything I have ever done. I have been in my present position ten years. You can do more for humanity in it than in anything else in the world.

This is all very gratifying to us as public health workers but the status of private duty nursing is gravely disquieting. What is the answer to the problem?

Clearly, it is not a mere increase in the number of women practicing a profession under conditions so unsatisfactory that barely half of those now in the field desire to continue in it. Equally clearly, as it seems to me, the solution must be found in better organization of the nursing service now at our disposal. Is it not obvious that the whole system of 24-hour nursing in the home by nurses working on a purely individualistic basis is bound to be costly to the patient and arduous and unrewarding to the nurse? Is it not obvious that better organization of the care of the sick will remove some of the objectionable features of the present plan by placing a certain proportion of the acutely ill, now cared for at home, in hospitals under group nursing care, and by handling another fraction through a considerable extension of the principle of hourly nursing? Is it not obvious that better organization of private duty nurses themselves will obviate most of the other difficulties, by distributing the total volume of nursing service as between city and country, by coördinated effort to cover holiday service, by intelligent selection of the type of nurse to fit the special case, by the cultivation of an *esprit de corps* that will prevent the scandal of refusal to take the responsibility for a difficult or a dangerous case?

I think the answer to these questions must be in the affirmative. When we come to the question how such organization can be effected there will be less unanimity. Shall it be accomplished by using the existing public health nursing organization in each community as a nucleus, or by the expansion of the functions of the Central Registry, or by the creation of a new coöperative organization of the private duty nurses themselves? Speaking for myself and not for the committee, I believe that the public health nursing organization is the agent for this work, and that if the public health nursing organizations do not rise to the opportunity, the whole cause will suffer immeasurably. If the organization of private duty nursing is to be effective, it must be carried out first of all with the interest of the public as a whole primarily in view; and secondly, it must be carried out with reference to the highest standards of professional performance. The public health nursing organizations are "public service corporations" in the highest sense of the term and they are the only organizations which have the supervisory force to make a community nursing service work, and work with success.

If the registries were to undertake the task they would be forced to build up a duplicate supervising staff, which would be wasteful and

almost impossible in view of the limited supply of qualified persons; and if by any miracle they succeeded the result would be to create parallel community nursing services, one for the rich and one for the poor, an outcome which would set our whole movement back ten years or more. What I hope may happen is that by the development of hourly nursing through the regular visiting nurse staff, by coöperation with the registry, and perhaps by the organization of a sort-of reserve corps of nurses available for 8 or 12 or 24-hour service—whether on a

THE TYPICAL MARCH WEEK
Private duty nurses worked less, worried more, were sick more, and rested less than the nurses in the other two groups

DAYS TOO SICK TO WORK
Each circle represents a day. During the week studied the typical private duty nurse lost 0.36 of a day because of sickness; the public health nurse lost 0.13 of a day; and the institutional nurse 0.09.

Shaded—hesitating
Black—planning to
leave field

KEEP ON?

"Do you intend to continue indefinitely in this type of work?" Of the private duty nurses 55% plan to stay and 45% are either hesitating or definitely planning to leave the field. Among public health nurses the corresponding figures are 85% and 15%, and among institutional nurses 82% and 18%.

YEARS OUT AND YEAR'S PAY

Average salaries received by private duty, public health, and institutional nurses who have been out from training school each number of years. (Institutional salaries include a flat allowance of \$500 a year for maintenance.)

salary basis or not I do not know, but all under sufficient supervision to guarantee adequate standards of service—by some such means as this, I hope to see nursing service in the homes of rich and poor, whether on a visit, an hourly, or on a daily basis, developed into one coördinated scheme of effective community service.

It is no easy task—perhaps it is an impossible task! I cannot but feel, however, that the problem is more likely to be solved by the visiting nurse associations with their prestige and with their command of so much of the best organizing ability of nurses and of lay directors than by any new organizations which might conceivably be developed for the purpose. It is because this problem presents so direct a challenge to many of the members of this section that I have dealt with it in so much detail.

JOB ANALYSES OF NURSING AND NURSE TEACHING

I must refer very briefly to the other two projects of the Grading Committee which as yet lie in the future. If the supply and demand study should indicate, as I suspect it may, that the community can get along with less rather than more nurses if their service is properly organized, but that a higher, rather than a lower, type of education is needed for the fulfillment of the demands of an adequate community program, we must next proceed to find out, so far as we can, what knowledge, training, capacities and qualities the nurse must have for success and how, and how far, these can be developed by education.

The method for doing this is what is known as job analysis! This means that we discover what a nurse should be like by studying her in action and seeing what she has to do. We list what she does, discover what problems she faces, and learn what she needs to know in order to meet them. When a careful analysis has been made of what the nurse needs to know and be, we then proceed to the second, and far more difficult process of analyzing the elements in the job of teaching her so that she will have these qualities.

This alluring, but very subtle and complex, task will be the major task of the committee during 1929 and 1930.

GRADING OF NURSING SCHOOLS

Meanwhile, however, the actual grading program will be worked out in parallel with the two study projects already discussed; and it is our plan to approach it along the following lines. To grade the 2300 training schools of the country on the basis of inspections would be enormously expensive and to grade them on the basis of the expert judgment of an inspector would require an inspectorate of an impossibly high caliber and would in any case provoke the defense reactions inevitably aroused by subjective criticism. The only solution would appear to lie in the use of relatively simple schedules of objective facts,

somewhat like the *Appraisal Form* of our Committee on Administrative Practice. Our task is to prepare a schedule which can be filled out at each school, by the authorities of the school itself, preferably with the aid of a representative of the committee, to serve not at all as an inspector but merely as an agent to explain the schedule and to secure uniformity in the interpretation of its items.

We hope to secure data on such a schedule for each of the 5 years covered in our study, beginning for 1927 with a few very simple and easily attainable items and including each year more items, and items less likely to be found in the machinery of the less developed schools.

So much for our method of obtaining the fundamental data upon which the standing of the schools will be ultimately based. How shall we set the standards to be met and how shall we grade the schools on the basis of the information thus obtained?

We shall not set any standards at all and we shall not grade the schools. We shall let them automatically set their own standards and automatically grade themselves. We shall, at the outset at least, publish no data for individual schools. We shall publish the distribution of schools by states in respect to each item studied and we shall inform each school where it stands on each item with respect to its fellows. Later on, as the schools begin to show improvement, it is possible that the names of those schools ranking in the highest third, or above some other determined level, may be announced. In any case, however, the standard of attainment will be set, not by the committee, but by the actual performance of the group as a whole. It will be a self standardization of the schools, by the schools, with the committee serving as a medium of intercommunication.

We believe that this plan will obviate any injustice to the weaker schools and will at the same time, through the force of emulation, produce a stimulus to improvement of almost incalculable force; and there is the added advantage that as the work of the schools improves standards will automatically rise. The program is on exactly the same general basis as the appraisal of community health service by the Committee on Administrative Practice which has notably succeeded in a constructive stimulation toward improvement without discouraging the more laggard and without checking the progress of the more advanced by standards which are fixed and arbitrary. We believe that this task, so performed, will offer the most powerful practical stimulus to the improvement of nursing education and will thus vitally serve the general cause of public health. We trust that the American Public Health Association may continue to support the work of the Committee on the Grading of Nursing Schools with this end in view.

Health Policies for Control of Public Water Supplies*

IN ITS REPORT for 1927 our committee has tried earnestly to comply with the instruction of the Committee on Committees to avoid overlapping the work of other committees interested in a similar topic. We are in thorough accord with the policy and hope future committees may, even voluntarily, be guided by it. However, it must be admitted that the specification adds to the difficulty of preparation of a report. Offsetting this, we are particularly favored in having Secretary A. E. Gorman suggest the title and treatment of the report we are about to make.

At the outset let it be said the report is less technical than in former years and is not so embrasive as its title might imply. It contains but brief reference to lines of policy or attitude toward a few of the problems appearing on the horizon for health officers or departments supervising water supplies.

First let us return to an old theme—the establishment of team-work between the health department and the water department. Water works employes need and want help and encouragement. It is unbecoming that the health officer should resort to high-handed supervision. Furthermore the courts in recent years have relieved health departments of much of the need of police regulation of water supplies through the frequency with which they have assessed damages against negligent water works. The health officer's task is made more pleasant and fruitful if he will simply capitalize the eagerness of the water department to do the right thing. With a united front both the health department and water department will get better consideration from their superior officers. Divided, they furnish ammunition for the politician.

SIMPLE CONTROL TESTS

The water department, like any other, is much benefitted by having a yard-stick with which to measure the results of its effort to produce a safe supply. Since chlorination is now so common a safeguard against contamination, the free chlorine test is especially valuable. With a few exceptions the test is simple, and with care to apply the test

* Report of the Committee on Water Supplies, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

to reasonably clear water, its results are exceedingly reliable. The test ought to be almost universal where water is chlorinated.

Next in order of practicability is the test for *B. coli*. If the water department can support a proper laboratory it should carry on its own *B. coli* control with only an infrequent check by the health department or state laboratory. If the water department cannot support such a laboratory the health department may have to handle the test as a routine matter, and if possible also the sampling. The better the grade of sampling the more constructive the test becomes, because the sampler can then correlate the operating conditions against laboratory results. Too often health departments leave sampling to mere errand boys.

Whoever makes the tests should be sure of the technic used and know how to interpret the results. The present *B. coli* standard is admittedly a very strict standard, but it is doing excellent work in making water departments more particular. In many parts of the country, however, where soil wash is a factor, *B. aerogenes* may completely confuse the interpretation. Some years ago anaerobic and aerobic spore formers also led to incomprehensible results. There is still much obscurity in the meaning of the appearance of *B. coli* in tap samples, the freshly treated water evidently being always safe.

The point in noting these exceptions is that water bacteriology is not on a plane where one can accept its findings with too much positiveness, especially if indicative of contamination. The water department may easily lose confidence in the health department if the results manifestly disagree with what common sense or experience would tell. An unfavorable result should therefore be the occasion for an open-minded, judicious inquiry as to what caused the apparent contamination. First feel sure of the laboratory end of the work and the sampling. Then, with the water department, try to run down the explanation. Unfavorable tests are most valuable when they lead to betterment in plant or operation.

OPERATING RECORDS

This leads us to remark on the value of keeping good operating records and we bespeak coöperation between the two departments in devising as simple a report system as the circumstances admit. It is easy to wander into framing complex record forms which so provoke the practical operator that they are not kept well or kept at all. It takes coöperation and familiarity with operating conditions to devise a usable, simple record sheet which tells just the essentials. The minimum record is one showing that chlorination doses have been reasonably uniform and results consistent. At the other extreme is a form

showing also the various factors influencing chlorine demand and condition of the chlorinator as well. But the record must be a truthful story of what actually happened, as far as is known.

Health departments should require the submission of summaries of the report at intervals to be determined by the weaknesses in the system. Except in emergency, a daily report to the health department is not warranted, and in fact defeats its purpose, which is to give the health department a bird's-eye view of plant functioning and an opportunity to scan for dangerous tendencies in operation. The water department is interested in the detailed results. The health department looks for evidence of glaring or suspicious faults in operation. Erratic operation is always suspicious, but so also is operation which is too even to be truthful.

SANITARY SURVEYS

Regardless of the kind of water works, every health department ought to become thoroughly familiar with the sanitary environment, safeguards and weaknesses of each supply under its supervision. The survey is indispensable as a means of gaining first acquaintance, and if thorough it will detect the hidden opportunities for future trouble. Moreover, the survey needs to be repeated from time to time—like the annual health examination which the modern physician is constantly holding up to us. This cannot be any superficial investigation. It must be thorough. Even then a condition may slip by unnoticed and lead to catastrophe later. Here is no place to elaborate on what a sanitary survey would constitute. It is too broad a subject for general discussion. If there is no one locally trained in sanitation of water supplies, the state sanitary engineer should be invited to undertake the job or suggest a procedure.

WATER CHLORINATION

Chlorination, even as now practiced, can take credit for a large part of the striking reduction in typhoid throughout the country. Yet its introduction has been notoriously not along conservative lines. The set-up is seldom in duplicate or calculated to guarantee continuity of service. We suspect that even now if faulty water chlorination were as strikingly shown as an interruption in power supply when the lights all go out, some startling evidence would appear. In its field, chlorination is quite as unique as power in the dependence placed upon it. Is it not singular that in the remainder of the water and power systems of the country you will find duplicate pumps, boilers, electric supply lines and duplicate service pipes; yet seldom indeed do you find a duplicate chlorination set-up? Sometimes duplicate parts for chlorinators are on hand, but there must be an interruption in chlorination while the sub-

stitution is being made. Now the additional precautions for continuous safety are simple and relatively inexpensive.

Many water works are not protected against the infrequent emergency. It is true of water works in general and of chlorination in particular, that the precautions depended upon must not merely take care of average conditions but be adequate to meet the severe emergency which might occur perhaps only once in five or ten years. Chlorination as it stands today is, in most cases, under just a mediocre control.

These considerations prompt the committee to report rather fully the exemplary precautions in chlorination taken by the City of Chicago under the direction of A. E. Gorman. No doubt there are other notable chlorine installations, but this one will serve to illustrate the care involved in good chlorination.

The set-ups at Chicago are predicted on the principle that every drop of water sent to the consumers needs adequate chlorination. The result of following the principle in that city has been one of the lowest typhoid records of any city in the country, where formerly outbreaks appeared every few years. The cost to consumers for this chlorination is triflingly low—a little over 5 cents per person per year.

Factors influencing chlorine demand, such as algae, pollution, temperature, pumpage, etc., were first evaluated and a chlorine set-up adequate to feed 6.5 lbs. per m.g. at maximum pumping period decided upon. A complete unit is installed in one booth, which is protected against temperature variations, and this is all duplicated in another booth. Leaks in one booth therefore do not hamper use of the other. Booths have vent systems, and gas masks kept ready for use are nearby in a special locker. Tank batteries are made up and set on scales in the booth. The number of cylinders is determined by the rule that the feed must not exceed 40 lbs. per tank per day. To guard against empty tanks it is not attempted in Chicago to use all the chlorine. The tare weight is known and the cylinders are replaced while there is still a pound or so of chlorine left in the cylinder. Batteries are so drawn upon that no two can run out within 6 hours of each other. In Baltimore the cylinders in any one battery all set on separate scales and cylinders are so put in service as to avoid all running empty at the same time.

Scales for weighing the chlorine are set flush with the floor to avoid damage due to impact. Scales are periodically tested for their accuracy.

Duplicate header systems run from both booths and connect to each battery and each chlorinator, all properly valved for control. Likewise the chlorine feed lines are in duplicate and points of feed are chosen so that the effect of a change in dose can be immediately felt. Water flow

rates are known at all times. The type of machines used prevents stoppages in feed lines and diffusers in cold weather and cold water.

Lines from the scales to the header are so arranged as to avoid transferring coil pressures to the scales, which would make weights incorrect. Machines are overhauled when a battery is out of service.

Chlorine attendants are on hand constantly. These men have been schooled in the machines and in chlorine tests. They keep the installation in good working order, test the treated water for residual chlorine every hour or more often in emergency, and attempt to keep the residual chlorine at 1 lb. per m.g. as it leaves the plant. They also keep records of operation.

The health department of the city performs the bacteriological work on samples it collects daily from the raw water, from each plant, and from several points in the distribution system.

Control of chlorination to guard against overdose, underdose, and tastes, is difficult when the set-up is at the head of a distribution system, as at Chicago, and subject to the effects of water draft and a fluctuating demand. The new installations will be automatic, the chlorinators being actuated by the water flows, thus getting away from at least that important variable. In systems where balancing reservoirs are used, and there are a few feet of head available, it is possible to precede the balancing reservoir with another just adequate to take the daily fluctuation, the inflow being constant for a day. In this case chlorine is applied to the constant inflow.

The committee is not prepared to advocate the chlorination of all water supplies, but it does favor a thorough job of chlorination where that method is indicated.

There is a growing number of supplies where the pollution load is heavy for so frail a precaution as is chlorination in practice. Such supplies, as a rule, suffer also in physical impairments. Health officers may well support the water department in agitation for water filtration in such places.

WATERSHED SANITATION

In watershed sanitation it appears to us that there is special need for health departments to have a more settled attitude, especially in control of recreation. In parts of the country supervision is woefully inadequate, left in the main to an innate sense of decency of recreationists themselves. In other states, as in New Jersey, regulation has swung too far against public opinion. At the instigation of a number of cities, regulations were adopted by the New Jersey State Board of Health at the close of 1926 forbidding bathing or the maintenance of bath houses and places of entertainment which would pollute water supplies. A

few months later the representatives of pleasure resorts, recreationists and land owners succeeded in having put into law, over the governor's veto, a bill which legalizes bathing in the waters of that state.

The pendulum must soon swing to a position more compatible with the various opposing uses of the watersheds. With typhoid disappearing and community water supplies coming more and more under treatment, the course health officers will take is apt to be decided on the score of decency more than anything else, considering all parties concerned in a clean watershed, and realizing that there is always reaction against restrictions in which the public does not have full credence.

It was not long ago that there was considerable resort to universal ownership of catchment areas. The doctrine of course is opposed to other uses of the watershed and its effect is to limit or totally deprive the commonwealth of pleasures or prosperity that may come from the widest harmonious use of the country's assets, of which the watersheds and streams required to supply water to our growing metropolitan areas represent a large item. The principle of watershed ownership has about reached the limit of its economic usefulness. It is tantamount to hoarding and opposed to greatest beneficial use.

In our opinion, health officers and departments must not take an extravagant position. They must look at the problem in a broad light, yet build up sentiment for decency and against abuse. They can easily appeal to the sense of cleanliness and fair play in a man and hence to his own self-interest. They need not let down the bars nor forego their police power, but when a broad viewpoint permeates the watershed policy the courts and the public are apt to support the health office in curbing unreasonable use more regularly than appears now to be the case.

Use of streams for sewage disposal, with more or less treatment of the sewage, has come to be an accepted, legitimate one. Water consumers have adjusted their works and their ideas to it. To the widespread recreational use of the watershed and streams, however, there is not yet the same adjustment or a settled policy. Sewage in recreational streams of course is inadmissible. For one thing it generally ruins the region itself for recreation. Swimming in streams appears now to be the most common sanitary problem and the hardest to tackle, being so generally indulged in and so slight in its sewage pollution. We suspect the real objection to it is principally a mental and esthetic one which, however, cannot be entirely overlooked.

Recreation of watersheds was one of the serious topics before the Conference of Sanitary Engineers in Chicago this year and subsequent committee reports may gradually crystalize a policy. The preliminary

discussions, however, served to show that regulation, if any, to work most fairly, must be local.

This much is certain, that water consumers cannot look to the recreationist or other users to guarantee the safety of the supply. The consumers themselves can easily make the supply safe and entirely potable. It is preposterous to deny mountain recreation to the multitudes that the consumers may be spared the inconvenience of water treatment. The health department will succeed well if it holds recreational abuse in bounds and preserves such a degree of cleanliness as the pleasurable uses themselves dictate.

Water departments have, in various parts of the country, adopted a more coöperative attitude toward permanent residents on watersheds in helping to maintain a high degree of sanitation, the department often furnishing plans, the material or even labor. It will be well to meet this new recreation problem in the same way. Without encouraging recreation unnecessarily, sanitary conveniences can be provided in whole or in part and appeals made which will promote a high standard. In some cases, in coöperating with owners of the land, fencing can be done and the public thus kept off.

CROSS-CONNECTIONS

As a closing topic for this report the committee directs attention to what it regards as a retardant in the program of cross-connection elimination due to rather dogmatic approach. A year or so ago water works men, underwriters, and state sanitary engineers took a definite and rather drastic stand against cross-connections. Many states have set out to eliminate them, even fixing time limits within which they must be out. It is not clear just what next move was contemplated in the event of non-compliance.

When the Health Department of Chicago first took up the cross-connection problem in 1924 and 1925, there was drawn up a drastic, prohibitory regulation. It has never been adopted. Instead, simply by inspections, more or less frequently repeated, most owners of the connections were finally made to see the possibility of harm as it actually existed in each case. The stand taken depended on how badly polluted was the secondary supply and the real extent of the menace to public health.

The regulating officer must not overlook the fact that he is dealing with lay people who have thought only of one side of cross-connections, namely, the advantage to themselves in having an augmented supply and reduced insurance rates. They may easily have overlooked the danger to health in perhaps a long experience of immunity from evil

results. If there is danger in the secondary supply, naturally the cross-connector would feel its force most. Therefore he should have the greater interest in the elimination of any real menace, if properly approached. The real reason for the existence of dual supplies is often an inadequate public one, and in such a case the main efforts should be directed at a better system.

In general, the attitude toward cross-connections is to eliminate them rather than to control them. Various states and municipalities, principally through their health departments, have adopted regulations patterned after resolutions of the American Water Works Association, Fire Protection Division and State Sanitary Engineers, prohibiting physical connection between potable public supplies and any other supply unless the secondary supply also be potable and under regular examination as to its quality. States that have given the subject a great deal of thought over many years are convinced that education and mere request for discontinuance of cross-connections are not enough and that specific, definite laws are needed, because even though the power implied in them may not be exercised frequently, the power is available to force action where lack of interest exists. The mere existence of penal provisions does not imply that everyone would resort to penalization initially, because most people can be dealt with through reason.

It is probably impossible for water departments and health departments to escape the burden of having to discover cross-connections with the distributing system, the same as they now must do in uncovering pollution acts at the very source of the supply; but with respect to parties who pollute the source of supply, misdemeanor laws, at least, are found on practically all statutes. It seems rather curious therefore that one cross-connecting to a public supply and polluting it—doubly a trespasser and a polluter—should be subject to no responsibility for the deaths or illness he causes, or to no penalties other than mere discontinuance of supply to him. So far as we know, no one has considered writing into the statutes, laws which would make it a misdemeanor to connect a private supply into a public one.

SUMMARY

By way of summary, a few of the points made in this report are:

1. Use coöperation and encouragement rather than the "big stick" in dealing with the water department.
2. See that a thorough sanitary survey is made to show how the system is operated, and ferret out all sanitary weaknesses which need watching. Repeat the survey every year or so.
3. If the supply is a chlorinated one, see that the free chlorine test at least is used. It will carry much assurance and stimulate the operator to improve his rec-

ord. Also see that the water department or the health department makes competent tests for *B. coli* and be sure of the interpretation of the results. Employ competent samplers who can correlate results against operation. Devise with the water department a good, simple record form. See that the health department gets summary reports of operation which will show dangerous tendencies and mismanagement.

4. Get away from being satisfied with mediocre results and control. Insist on a reliably safe water all the time. Guard against not only those conditions regularly bad but against hazards which occur once in several years. As for chlorination, when it is needed, insist on installations that practically guarantee the disinfection of every drop of water sent to consumers. For instance, require all installations to be in duplicate, together with interconnecting lines, and see that there is never an interruption in the proper chlorine feed.

5. What to do with recreation on watersheds is a most imminent problem. The most pressing phase is the swimming problem in water supply streams, entertainment on a large scale, and hunting and fishing. We cannot help moralizing on the happenings in New Jersey when the State Board of Health prohibited swimming and entertainment on water supplies, and the kick-back was that resort owners, real estate subdividers, and individual owners along the stream secured the passage of a law over the governor's veto that legalizes swimming and bathing in the waters of the state.

The problem is to keep down recreational abuse if only to perpetuate its enjoyment. Look on watersheds not as a single asset but as having multiple uses of value and try and harmonize all with the least inconvenience and restriction needed to preserve each one. The minimum need is for clean, decent uses of the watersheds. In recreational areas sewage pollution is dangerous and will wreck the region if not curbed. Swimming should be considered more for its uncleanly effects on the stream. As a source of dangerous pollution it is of little importance. We are equally certain that water departments can easily, and therefore must, take the balance of the burden of protecting their own supplies by adequate water purification. We also commend that they cooperate in maintaining sanitary conveniences and safeguards on watersheds from which they take their supplies.

6. The formula for dealing with cross-connections appears to lie in the adoption of local and state regulations prohibiting such cross-connections, intakes, bypasses and other dual supplies unless the same be of known potable quality. In the administration of such a prohibitory ordinance, the powers provided by such regulation are to be looked upon as a reserve measure when education fails, in particular instances. The formula must further provide for the detection of cross-connections. That is easier in a publicly-owned system than in a privately-owned one, because if the owner of the premises forbids, he can prevent the company employees from entering.

We would throw out the suggestion, further, that cross-connections and consequent pollution should be made a misdemeanor offense, the same as has long been the case with respect to acts of pollution on the watershed and other parts of the system.

Activities of Plankton in the Natural Purification of Polluted Water*

W. C. PURDY

U. S. Public Health Service, Cincinnati, O.

AS a rule, plankton and related organisms are most abundant in water which is in process of recovery from pollution by sewage, that is, during the period of natural purification. Hence we may inquire, (1) Are the activities of these organisms a part of the program of natural purification? (2) What effects, if any, are produced on the water by the presence and activities of these minute forms of life? and (3) What are some of the activities?

Biologically speaking, these microscopic organisms are low in the scale of life, have little differentiation, and relatively few activities, these being concerned chiefly with obtaining food and reproduction of species. From the standpoint of effect upon the water, the matter of food supply would seem to be dominant, and this may be discussed with advantage under the subheads—(1) plankton food, (2) photosynthesis, and (3) expenditure of plankton energy.

Some years ago a noted German investigator, Dr. Marsson, classified all plankton organisms as "food producers" and "food consumers," including in the latter class those organisms which by means of lash, cilia, or other appendage directed a current into their mouth-vacuole or gullet, thereby obtaining minute particles of food, including bacteria. Many other workers both here and abroad have observed and recorded the consistent tendency of certain plankton forms, conveniently designated "pollution organisms," to become numerous when sewage is present and bacterial content is high, and the subsequent decrease or disappearance of these same organisms when bacterial content becomes low. There is abundant presumptive evidence of this sort to the effect that certain plankton organisms necessarily find much of their food in bacteria, not only because of the simultaneous fluctuations of the numbers of the two classes of organisms, but also because of the observed methods of feeding, and the body structure of the plankton organisms as indicated by Dr. Marsson, above quoted. In fact, it would be diffi-

* Read before the Laboratory Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 21, 1927.

CHART I

cult, or impossible perhaps, for the feeding plankton organism to avoid ingesting large numbers of bacteria.

In three rivers thus far studied (Potomac, Ohio and Illinois), these pollutional organisms are most numerous in that part of the stream where pollution is physically evident, and decrease rapidly as the water regains normal condition. Chart I, showing decreasing bacterial content, and decreasing pollutional plankton meantime, is based on Illinois River data, and is, in general, representative of the other streams.

There is, however, quite satisfactory evidence, based on careful laboratory tests, that certain of these pollution organisms are able to consume very large numbers of bacteria, the plankton meantime increasing greatly in numbers. A brief report of these tests was published in 1918.¹ From that report we present herewith Chart IV, and one or two unpublished ones relative to the same tests.

CHART II

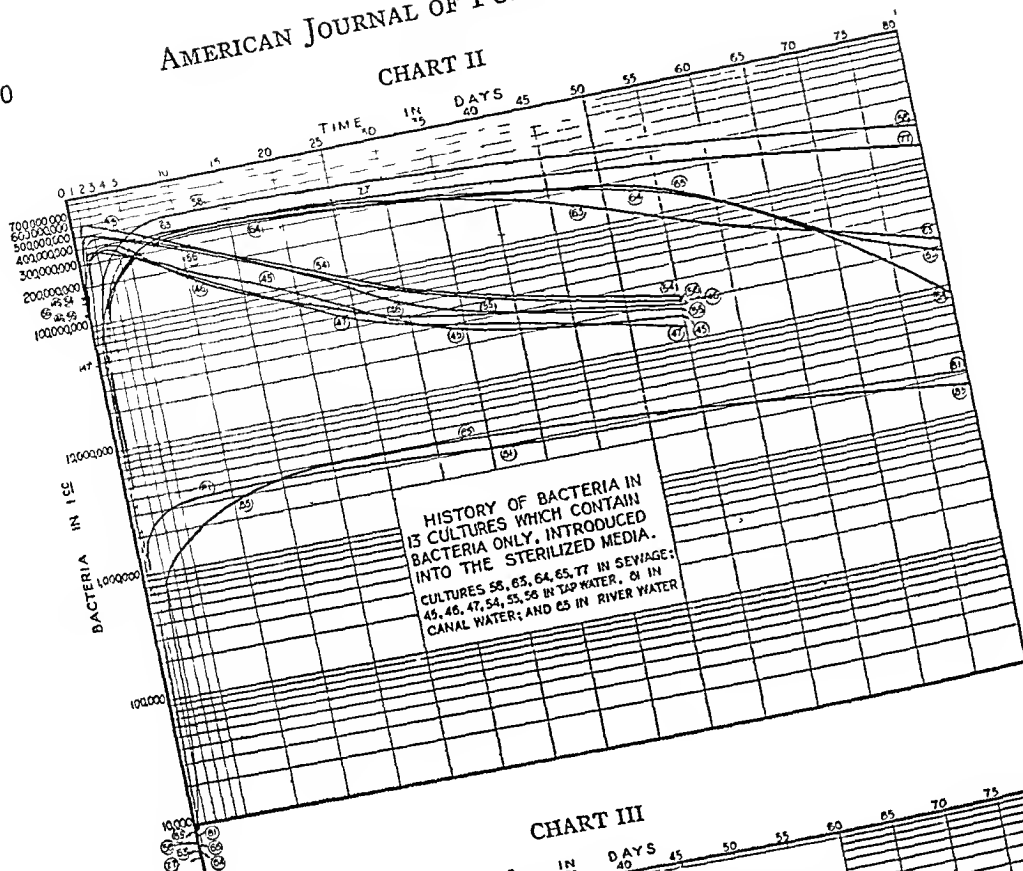

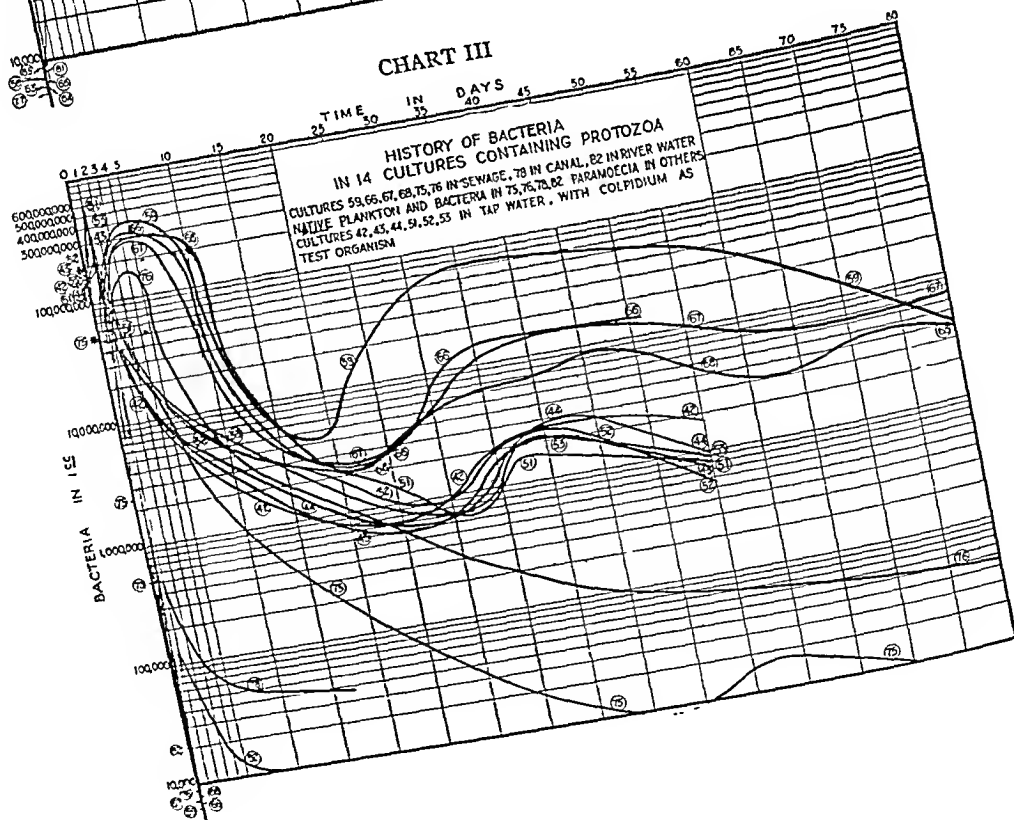

CHART III

Essential results of these tests were as follows,

1. Sterilized sewage, inoculated with bacteria only, reached a very high count in 4 to 6 days and maintained this for 6 to 10 weeks.
2. Sterilized sewage, inoculated with bacteria and also with pollutional protozoa, showed high bacterial maximum in 4 to 6 days, then shortly heavy and rapid reduction, with rapid increase in protozoa about the time of greatest bacterial decrease.

These experiments, repeated many times, always gave essentially the same results, as shown by Charts II and III.

All of the cultures shown in Chart II were of sterilized medium inoculated with bacteria only.

All of the cultures in Chart III were identical with those in Chart II, except for the presence of protozoa in the cultures. It will be noted that the bacterial history is very different. Comparison can best be made by inspection of Chart IV, here shown.

Culture 65 contains bacteria only. The very high content is maintained for about 60 days. Culture 68 is identical except that it contains protozoa, in addition to bacteria. It will be seen that, in this culture, the high bacterial content drops suddenly. It seems significant that the protozoa increase rapidly meantime.

One culture of sterilized sewage was inoculated with bacteria-free protozoa (paramecia). Apparently the minute organic detritus present, and the dissolved materials, did not constitute suitable food, for all the paramecia died within 4 days. After 14 days this same medium, still bacteria-free, was again inoculated with paramecia, but bacteria were added this time. The paramecia multiplied more than a hundredfold under these conditions.

In view of all these results, as stated, it seems difficult to offer any satisfactory explanation other than that the paramecium, a typical pollution organism, consumed bacteria in large numbers. Apparent confirmation of this food habit is indicated by the speedy death of paramecia in the culture which contained no bacteria, and subsequently by the immediate increase of other paramecia in this identical flask of sterile sewage when bacteria were added.

Further laboratory tests indicate that colpidium, another typical pollution organism, is capable of living in a liquid medium (ordinary broth) without bacteria, but it failed to live in sterile sewage without bacteria added. Moreover, it will live in sterile water to which has been added a suspension of bacteria only. These facts indicate the probability that colpidium is in nature a consumer of bacteria, but that life is possible for it with a diet of dissolved organic matter alone, such as

CHART IV

broth, provided this be of suitable strength. It has been suggested (by Mr. Butterfield, I believe) that the bacteria are merely the convenient agents to gather or harvest from the water and store within their bodies the highly-diluted soluble organic matter which, in the more concentrated form represented by the resulting bacterial bodies, is suitable food for colpidia and for other protozoa as well.

PHOTOSYNTHESIS

A second major activity of plankton relative to food habits should be mentioned. Reference is made to photosynthesis, by which the chlorophyll-bearing organisms of the plankton, mostly plants, dissociate carbon dioxide and water in the presence of sunlight, and in recombining the elements to form starch, the basis of their nutrition, the excess oxygen is given off as a waste product. Unless the water is already saturated, this oxygen will be dissolved to some extent and may be utilized, if needed, in the aerobic decomposition of organic matter.

Beyond the brief statement of this activity, we have as yet no experimental data to offer. We may state, however, that even in such a polluted stream as the Illinois River the major part of the plankton, volume for volume, is of the chlorophyll-bearing, oxygen-producing sort, and we venture the opinion that adequate study of this unique

activity of the plankton may result in a high rating as to its significance in the program of natural purification.

EXPENDITURE OF ENERGY

1. *Locomotion*—Under the microscope, the plankton activity that is most apparent is that of physical movement. Ciliates scurry to and fro apparently at breakneck speed. Flagellates glide slowly, pulled by their one or two rotating flagella extending a body-length ahead. Oxytricha and its kind move forward, suddenly go in reverse for half a body-length, change direction and again go forward, and so on indefinitely, pursuing a most erratic course. Rotifers start their "wheels" and are thereby pulled through the water as an airplane is pulled by its propeller. Nematodes produce a series of minute maelstroms by their violent contortions, and cyclops, speediest swimmer of the plankton, together with certain other crustacea, travel by a series of leaps or jumps that have given them their popular name of "water fleas."

While the apparent speed of these minute forms is great, the actual speed is very low. A colpidium will cover nearly 1 millimeter per second, a paramecium 3 millimeters, a rotifer 2. But consideration of the *relative* speed shows that the colpidium, 50 microns long, is traveling about 20 times its own length in 1 second, the paramecium 12 times its length, the rotifer 5 or 6 times. A cyclops, hurling its sturdy body through the water 70 or 80 millimeters per second and covering about 100 times its own length meantime, holds the palm. Such relative speeds are impossible for our best motor boats.

But water, being mobile and noncompressible, is locally disturbed and displaced by the movement of a submerged body. In the case of the plankton, the submerged body is self-propelled by its lashing the water with numerous minute cilia, like microscopic oars, or by the rotary movement of flagella, simulating propellers, or by the powerful strokes of paired lateral swimming organs. The disturbance of water thus produced extends far beyond the limits of the body causing the disturbance, as the oars and propeller of a boat produce currents and eddies a boat's length or more away. A paramecium will thus cause minute but violent agitation of the surrounding water to a distance of 100 microns or more on all sides. If 50 paramecia are present in 1 cubic centimeter of water, these will, in about two minutes, subject every particle of this water to this minute and intimate mixing. In like manner, 100 colpidia will, in 22 minutes, minutely mix every portion of 1 cubic centimeter of water. Polluted water usually contains various other motile forms also, some nearly or quite as large as paramecium, others exceedingly minute, but very numerous and usually very active.

2. *Movement of attached organisms*—There are also other organisms, not free-swimming, but attached to any convenient anchorage, at the water's surface, on the bottom, at the margins, or even on small masses of suspended matter. Such organisms, usually in groups or colonies, are mainly of the vorticella type. On the open end of their bell-shaped bodies are rows of cilia in practically constant motion, bringing to each organism a minute but continuous current of water. These colonial forms are amazingly abundant in a sewage polluted stream, forming a whitish feathery coating on bottom stones or trailing from any available submerged attachment. One cubic centimeter of this whitish growth may contain over 200,000 of these minute bell-shaped organisms, and every one of these is engaged in producing the continuous microscopic water current referred to.

The sum total of the minute mixing which these various plankton organisms impose upon the polluted water must be sufficiently great to merit consideration. It is frequently the case that there are present more than 50 paramecia and 100 colpidia per cubic centimeter. But if only these be present, their movements will cause minute, intimate mixing of 1 cubic centimeter of water in one and three-fourths minutes. This being the case, it is surely a conservative estimate to credit the total population of microscopic protozoa of polluted water with complete and intimate mixture of 1 cubic centimeter of water in 1 minute. The process might be conveniently and adequately indicated by the aphorism, "Minute mixing each minute."

Effects—What is the probable effect of such minute continuous mixing and microscopic circulation thus imposed on polluted water during the period of its greatest pollution? We can only say, in the absence of experimental data, which so far as we are aware have not yet been obtained or even attempted by any one, that human experience from time immemorial and in many lines attests the great value—the absolute necessity—of thorough and intimate mixing of ingredients if proper results are to be obtained within reasonable time. In more recent years, the activated sludge process has furnished a striking example of this. It therefore seems reasonable to suppose that this microscopic circulation and minute mixing caused by plankton movements during the critical initial stages of natural purification of polluted water may be a factor of importance in the successful and speedy progress of such purification. In our laboratory, cultures of sewage, containing bacteria only, retained their foul odor and their milky turbidity for 8 weeks or more, while like cultures, which however contained actively motile plankton organisms in addition to bacteria, lost their turbidity and their foul odor in about 10 days. It is possible that

the continuous movements of the plankton organisms were a factor in the latter case. More specifically, we may indicate one result which appears to come from this plankton activity.

These organisms find their food in the polluted water, for they live and multiply therein. As the water slowly regains normal condition apparently this food slowly disappears also, for the organisms lose their plumpness, become thin, then gradually disappear. Apparently the organic matter that constitutes the *pollution* of the water constitutes also, to a great extent, the direct or indirect food of certain plankton organisms that are then numerous. Thus a portion of this polluting organic matter of the water reappears as a multitude of minute living organisms whose rapid and continuous movements represent the *energy* of the organic food they have consumed. In other words, a portion of the harmful organic matter is consumed, then released to the water in terms of motion. Latent energy in harmful organic form has now become kinetic and harmless, and is made to do work concerned with the betterment of the water itself. Correlation of energy is effected, and the polluted water is started on the road to recovery.

3. *Movement of larger organisms*—Certain larger organisms attack masses of organic matter or work in the bottom sediments. *Cypris*, a plankton crustacean, works the surface of sediment over and over until this is reduced to a state of microscopic fineness. The naiid worm *Dero*, occasionally found in the plankton, is frequently very abundant in heavy surface films, where it attacks and burrows into masses of organic matter, apparently eating almost continuously, judging from the great frequency and relatively large amount of its fecal excretions meantime. *Limnodrilus*, an oligochaete worm which does not belong to the plankton proper, delves in rank bottom sediments and works these over, excavating beneath the mud surface and depositing this material on the sediment surface in the form of great numbers of fecal pellets dropped from the anal end waving to and fro meantime in the overlying water. Certain other organisms also help to reduce these larger masses of organic matter or of sediment, but the three just mentioned are outstanding in their activity.

SUMMARY

It is our opinion that the activities of plankton and related organisms constitute a part of the program of natural purification of polluted water, in that their food habits tend to remove a portion of the organic matter, the photosynthetic activities of chlorophyll-bearing organisms operate to produce oxygen, and the energy of harmful organic matter consumed as food and released to the water in terms of motion, serves to furnish an intimate mixing and microscopic circulation during the critical initial stages of recovery from pollution.

The Residual Germicidal Action of Water Treated with Ultra-Violet Light*

JOHN F. NORTON, PH.D., FELLOW A. P. H. A.

*Department of Hygiene and Bacteriology, University of Chicago,
Chicago, Ill.*

THE WORK of Steenbock¹ and his associates, of Hess² and his coworkers, and of others, has demonstrated that fats and oils and certain lipoidal substances can be activated for the prevention of rickets by exposure to ultra-violet light. If the light rays absorbed and then slowly emitted are responsible for this antirachitic activity, it is not unreasonable to expect that such irradiated materials might also exert a germicidal action. Such a possibility was suggested many years ago and denied by Cernovodeanu and Henri³ in 1910. The question was again raised in 1921 by Walker and Pryer.⁴ They concluded that water after exposure to an ultra-violet lamp retained some germicidal activity which was sufficient to destroy a certain percentage of added bacteria, and that this property was dependent upon the amount of electrical energy consumed by the ultra-violet lamp. I have been unable to find any further published material bearing on these claims, except a statement in an article by Coblenz⁵ to the effect that ultra-violet light of high intensities affected nutrient agar so as to cause a "considerable mortality" among *Bact. coli* with which the agar plate was inoculated.

In view of the fact that the claims made by Walker and Pryer have not been generally accepted in spite of the somewhat striking experimental data obtained by them, it seemed desirable to reinvestigate this supposed residual germicidal action and, if positive results were obtained, to study the factors involved, particularly in relation to the composition of the exposed water.

Our first experiments were made with Chicago tap water. This is a water of moderate mineral content and with relatively small contamination from sewage or trade wastes. Before entering the ultra-violet ray machine the water was passed through a bone black filter to remove any traces of chlorine. The samples used for our experiments were tested, as a matter of routine, for chlorine with ortho-tolidin. All tests

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

were negative. Two commercial ultra-violet light sterilizers were used. One operated on a 110 volt electric circuit. The actual voltages across the lamp during operation varied from 70 to 75 volts. The current was maintained at 4 amperes. The energy consumed was between 280 and 300 watts. The capacity of the machine was about 350 gallons per hour. This same machine was also used with a lamp operated at 80, 90 and 120 volts and 5 amperes, giving wattages from 400 to 600. The other machine was operated on a 220 volt circuit and had a capacity of 1,500 gallons per hour. Our pressure was not sufficient to maintain such a rate of flow. The actual rates during operation varied between 300 and 360 gallons. This should be noted in connection with the interpretation of our results, since the time of exposure of the water to the lamp was much longer than that for which the sterilizer was designed. The voltage across the lamp during operation was 170 and the amperage varied between 4 and 4.5, giving wattages from 680 to 765. A few experiments were made with a lamp which was operated at 200 volts and from 4 to 8 amperes. The energy consumed varied in different experiments from 800 to 1600 watts.

Most of our experiments were made with a Rawlings strain of *Bact. typhosum*. Some tests were also made with a strain of *Staph. aureus* and a few with a culture of Friedländer's bacillus. The number of bacteria was determined by nutrient agar plate counts.

The method of procedure to study any possible residual germicidal action was as follows: The machine was started and allowed to operate for 2 to 4 hours before samples were collected. For each test two samples were taken—one immediately before the water entered the sterilizer and the other as the water left the machine. The samples were collected in sterile glass stoppered bottles. Both the control and test specimens were inoculated with organisms from a 24-hour broth culture after being centrifugated and washed three times with sterile saline. The numbers of organisms added per cc. of sample varied from 150 to 5,250. Agar plate counts were made immediately after inoculation and again after 30 minutes. In some cases counts were also made after 1 and 2 hours. Colonies were counted after 24 hours' incubation at 37°C.

Thirty experiments were made. Except in two instances there was a decrease in the colony count both in the control and sterilized specimens during the first half hour after inoculation. This decrease was not greater in the sterilized than in the control samples. Samples of each kept for 24 hours showed enormous increase in bacterial count.

Our conclusions are based on a comparison of the agar counts from the inoculated sterilized water with those from the inoculated untreated

LABORATORY

C. C. YOUNG

MODIFIED SEDIMENT TEST FOR VISIBLE DIRT ADOPTED IN CONNECTICUT

FRIEND LEE MICKLE, M.S., FELLOW A. P. H. A.

Director of Laboratories, Connecticut Department of Health, Hartford, Conn.

DURING 1926 it was brought to the attention of the Connecticut State Department of Health that the sediment test for visible dirt in milk, as carried out in several of the approved laboratories of the state, varied considerably in the technic used, although supposedly each laboratory had been conforming with the procedures specified in the *Standard Methods of Milk Analysis* of the American Public Health Association.

A meeting was called to which all interested persons were invited. At that time the fourth edition of *Standard Methods* (1923) was in use and each laboratory was using standards prepared in the manner specified in that report, by adding dirt to milk. By request, the standard discs used in each laboratory were brought to the meeting, and it was very evident that no close uniformity could be expected with the use of standards which varied so greatly. The variations seemed to be due primarily to the use of samples of dirt of different sizes of particles, different colors, to difference in technic in preparing standards and to a variety of ways of interpreting the directions in *Standard Methods*.

It was the consensus of the meeting that photographic standards prepared by one set of workers and supplied to all the laboratories in the state making the test would be the solution of the problem. A committee was appointed to make tests and prepare photographic standards. The studies made extended throughout the year, and one meeting

was held with the Referee of the Committee on Standard Methods of the American Public Health Association. Finally, on January 9, 1928, a second meeting of milk laboratory workers was called to discuss the report of the committee. The report was adopted with minor changes.

The method for the sediment test as given in the fifth edition of *Standard Methods of Milk Analysis* (1928) was adopted inasmuch as, during the time that had elapsed, the Fifth Edition had appeared recommending a photographic standard. A number of additional procedures, not in conflict with those of *Standard Methods*, were adopted to meet Connecticut conditions, however, because it was felt the method in the Fifth Edition does not provide sufficiently for the examination of bottled milk. It was found the bulk of laboratory milk examinations in Connecticut is of samples of bottled milk. A standard photograph, showing four additional gauges for use on bottled milk, has been prepared by the committee for distribution. All of these discs are graded as clean to conform with *Standard Methods*, but represent, respectively 0.25, 0.50, 0.75 and 1.00 mg. of dirt per pint. It was decided to return to the dairyman or health official the disc showing the dirt removed from each sample of milk attached to the report. Only the Wisconsin sediment tester and the discs of the type furnished by the manufacturer of that model were allowed where *Standard Methods* provides

that this or several other types of testers may be used.

The method, exactly as adopted at the meeting of milk laboratory workers, January, 1928, for use by all Connecticut approved laboratories, follows:

1. The method for the sediment test given in *Standard Methods of Milk Analysis* of the American Public Health Association and the Association of Official Agricultural Chemists, fifth edition, pages 32-34, was adopted. The following additional procedures which are not in conflict with those of *Standard Methods* were adopted to meet Connecticut conditions.

2. Pint samples only shall be regarded as standard. Where quart or any other size of sample is used, the report must state the size used. (The question of whether or not these results should be calculated to a pint basis, as recommended by the committee, was left undecided for later action with the provision that meantime each laboratory may so calculate or not as they prefer.)

3. Only the Wisconsin (Lorenz model) sediment tester shall be used.

4. Only the discs of the type furnished by the manufacturer of the Lorenz model shall be used, although they may be purchased from any source.

5. The sediment discs obtained from filtering samples of milk shall be graded against the photographs on page 33 of *Standard Methods* or against the extra prints of these photographs obtainable from the American Public Health Association, New York, N. Y. (These cost 75c each for either set A, B, or C or \$2.25 for the three sets of pictures on page 33 of *Standard Methods*.)

6. *Standard Methods* directions shall be interpreted to mean that no person shall prepare standards by adding dirt to milk.

7. The photographs show five gauges (see top of column opposite).

All samples shall be reported by one of the five descriptive terms above and also scored in terms of either 1.25, 2.50, 3.75 or 5.00 which are figures representing milligrams of dirt per pint. In order to avoid confusion the two

DESCRIPTION	MG. DIRT PER PINT
Clean	0.00
Fairly clean	1.25
Slightly dirty	2.50
Dirty	3.75
Very dirty	5.00

figures at the right of the decimal point should always be used whether or not the last figure is a cipher.

8. Percentage-clean figures and terms other than the above for expressing dirt in milk shall be completely abandoned.

9. No sample showing more than 1.25 mg. dirt per pint shall be reported within closer limits than the five gauges given above, the dairymen being given the benefit of any doubt in deciding between any two of the five gauges.

10. *Standard Methods* states where bottled milk is examined it should not show even 1.25 mg. dirt per pint. For milk reported as clean there shall be, for Connecticut use, an additional standard photograph of discs showing, respectively, 0.25, 0.50, 0.75 and 1.00 mg. dirt per pint. (Copies of this photograph may be obtained from the Bureau of Laboratories, State Department of Health, Hartford, Conn., at 50 cents apiece, mounted either on 3" x 5" or 4" x 6" filing cards, so long as the supply of both sizes lasts, providing you state a preference in ordering. Write Friend Lee Mickle, Chairman, Milk Sediment Committee.)

11. All milk samples graded as clean shall be reported in the following terms which are figures representing a milligram or fraction of a milligram of dirt per pint:

Clean	0.00
Clean	0.25
Clean	0.50
Clean	0.75
Clean	1.00

12. No clean sample shall be reported within closer limits than the five grades on the photograph, the dairyman being given the benefit of any doubt.

13. The discs shall be returned to the dairyman, health or dairy official, or milk inspector, together with the report.

BACTERIOLOGICAL METHODS OF EXAMINING ICE CREAM *

THE increasing interest in the sanitary control of ice cream stimulated the American Dairy Science Association to appoint a committee on bacteriological methods of analysis of this product. The report of this committee was published in a recent issue of the *Journal of Dairy Science*.¹

The first part of this report includes detailed directions for the agar plate, and direct microscopic methods of analysis as applied to ice cream. Directions are given for the preparation and sterilization of glassware for bacteriological work, and for the preparation of media for ice cream analysis. Considerable space is given to a discussion of the methods of sampling the various ingredients of ice cream, as well as the frozen product, and to the method of measuring the sample for the gravimetric and volumetric determinations.

The last part of the report involves a discussion of the value and significance of bacterial analysis in the sanitary control of ice cream. The importance of various factors in controlling the sanitary quality of ice cream, such as the quality of ingredients, plant sanitation, contamination from human sources, use of chemical disinfectants and steam, etc., are discussed in detail. Directions are given for taking samples to detect faulty conditions in the plant operation.

The report of this committee should be of interest to anyone who is attempting to do laboratory control work with ice cream.

Through the agency of the journals, the committee wishes to enlist the coöperation and assistance of everyone who is doing work along the line of labora-

tory control of ice cream. Any new methods or modifications of old methods which may have proved satisfactory will be gladly received by the committee. It is the desire and aim of this committee to serve as a medium through which improved methods may be collected and passed on to others. It is not intended to propose an official method, but rather to make available to the industry all bacteriological methods which have been found satisfactory.

It may be of interest to know that the American Dairy Science Association, through its General Committee on Bacteriologic Methods of Analyzing Dairy Products, with Dr. R. S. Breed as chairman, is contemplating the formulation of a complete set of bacteriological methods for all the dairy products. This general committee expects to function largely through sub-committees, composed of men who have had experience with the various dairy products. A sub-committee on methods for analyzing butter is now actively at work; another on condensed and powdered milk products has recently been appointed; and the sub-committee on ice cream has recently published the report referred to.¹ The sub-committee on ice cream consists of A. C. Fay, Chairman, Kansas Experiment Station, Manhattan, Kan.; F. W. Fabian, Michigan Experiment Station, East Lansing, Mich.; and B. W. Hammer, Iowa Experiment Station, Ames, Ia.

NOTE: The methods herein suggested have not come before the Committee on Standard Methods of the American Public Health Association for approval and, therefore, do not represent the opinion of the Association.

1. Bacteriological Methods of Examining Ice Cream. *J. Dairy Sci.*, 10, 5:460-478, 1927. The pre-publication demand for this report has necessitated a charge of 25 cents for reprints. They may be procured from Dr. Robert S. Breed, N. Y. Agr. Experiment Station, Geneva, N. Y.

* Submitted by a Committee from American Dairy Science Association.

VITAL STATISTICS

LOUIS I. DUBLIN, PH.D.

Mortality Experience of the Metropolitan Life Insurance Company for the First Quarter of 1928— The mortality records of the industrial policy holders of the Metropolitan Life Insurance Company show that the first quarter of 1928 shared with the corresponding period of 1927 the distinction of registering the lowest death rate (9.7 per 1,000) ever recorded for these 3 months among the industrial populations of the United States and Canada. Among approximately 16,000,000 white insured persons, the rate was only 8.8 but among about 2½ million colored persons, there was an increase to 15.9 per 1,000, from 15.5 last year; so that the composite figure for the two races showed no improvement.

The death rate for tuberculosis among the white policy holders was 72.0 per 100,000. This is not only a new minimum for any first quarter, but shows an improvement of 11 per cent over the previous minimum of 80.8 registered only last year. Within 2 years the tuberculosis death rate among white wage-earners has been cut by one-sixth. In half a decade it has been cut approximately one-third. It has been almost halved since 1920. Corresponding improvement has not been registered for the insured colored population, among whom there was actually a higher rate than during the early months of last year. Their rate of 229.3 for the quarter may be compared with 245.6 in 1923 and 310.1 in 1920, a drop of 26 per cent in 8 years.

The mortality record for the quarter shows gratifying declines among both white and colored for typhoid fever, scarlet fever and whooping cough. The

measles mortality shows a small drop for the whites and a large increase for the colored. The diphtheria situation is by no means encouraging, although the rate for the colored is lower than in 1927. Last year it was believed that the increase was only a temporary phase in a situation that had previously shown improvement for 6 continuous years. This viewpoint must now be discarded and a still more earnest campaign conducted for the immunization of children against this disease. The increased prevalence of meningococcus meningitis was reflected in a rather marked increase in the death rate among Metropolitan industrial policy holders. The combined mortality from influenza and pneumonia was a little higher than in the early part of 1927. Pneumonia, in particular, showed a considerable increase among the whites. Two other diseases of outstanding public health interest, diarrheal complaints and puerperal conditions, show improvement. In the case of the latter, the drop is considerable—more particularly among the colored.

The cancer rate for whites and colored persons during the first quarter was 75.3 per 100,000, as compared with 75.1 last year. The death rate for the whites declined a little during last year, and but for a very pronounced rise among the colored policy holders, the composite rate would have dropped slightly. The mortality from diabetes continues to increase—very slightly among the whites, but pronouncedly among the negroes. The conclusion that little benefit has as yet come to the urban negro as the result of the discovery of insulin, is inescapable. Insured urban negroes not only show a

sharply increasing diabetes death rate, but their rate is now higher than that of the whites. Suicides, homicides and accidents all registered lower death rates for both the white and the colored policy holders with the greater improvement in each instance resting with the latter. The death rate from automobile accidents for the whites increased 9.4 per cent over that for the first quarter of 1927 and 14.8 per cent over 1926. For the negroes there was an increase of 5 per cent over 1927 and 37.3 per cent over 1926.—*Stat. Bull.* 9:1-5 (Apr.), 1928.

Current State Mortality Statistics

—The U. S. Public Health Service has begun publication of tables from the monthly mortality reports of state health departments for the latest month for which published records are available. Statistics of most communicable diseases are not included, since they are available in other tabulations in the *Public Health Reports*. Statistics of deaths from other causes are limited for the most part to those causes which appear in the state reports. In the case of states which publish detailed mortality reports each month, the record of only the principal groups of causes and certain important specific causes have been used.

For purposes of comparison, the mortality records for the corresponding month in a few preceding years have been compiled. The rates have been computed upon the populations as estimated for July 1 of each year represented. These tabulations will be enlarged as the current data on mortality from additional states become available.—*Pub. Health Rep.* 43:743 (Mar. 30), 1928.

The Health Record of University Students as Related to Tonsillectomy
—Twenty-eight per cent of the 978 men students and 32.5 per cent of the 578

women students of the class of 1926 at the University of Michigan had had their tonsils removed before entering college. In the class of 1929 this figure had risen to 35 per cent of the 1523 men students. Data from the records taken at entrance and during the college course fail to show any significant difference between the health of the two groups. There was slight advantage, however, to the tonsillectomized group in general health and nutrition.

Only 6 per cent of the 275 students with their tonsils removed, and 16 per cent of 703 students with tonsils, had had cervical adenopathy. The tonsillectomized students had more trouble with upper acute respiratory infections, 63 per cent of 537 tonsillectomized students suffering thus, in comparison with 45 per cent of the 986 non-tonsillectomized ones.—Warren E. Forsythe, *Pub. Health Rep.* 43:560-563 (Mar. 9), 1928.

Mortality Statistics of Prussia, 1926—In Prussia, exclusive of the Saar region, the total number of deaths in 1926 and 1925 was 445,754 and 450,973, respectively, or 115.9 and 118.5, respectively, per 10,000 population. The death rate for 1926 declined by 2.6 per 10,000 population, as compared with that of 1925. In 1925, the reduction in the total number of deaths, as against 1924, 3.3 per 10,000 population, whereas, from 1923 to 1924, a reduction of 13.7 per 10,000 population, had been recorded. Almost one-fourth (22.9 per cent) of the deaths recorded in 1926 (102,269, or 26.6 per 10,000 population) resulted from transmissible diseases. The rate per 10,000 population for the remaining causes of death was as follows (the rates for 1925 being in parenthesis): diseases of the circulatory organs, 17.1 (17.1); senile weakness, 12.1 (12.1); cancer and other neoplasms, 11.2 (10.8); cerebral hemorrhage and other diseases of the nervous system,

9.6 (9.8); diseases of digestive organs, 9.0 (9.3); congenital lack of vitality and developmental defects, 6.8 (7.3); diseases of the respiratory organs, 4.5 (4.4); accidents or other violent forces, 3.8 (4.0); diseases of the urinary or genital organs, 3.0 (2.9); suicide, 2.5 (2.4); deaths in childbed, exclusive of childbed fever, 0.5 (0.5); murder and homicide, 0.2 (0.2).—*J. A. M. A.* 90:995 (Mar. 24), 1928.

Public Health in Palestine and Trans-Jordania, 1926 — The report made by H. M. Government to the Council of the League of Nations on the administration of Palestine and Trans-Jordania for the year 1926 has been issued from the Colonial Office. In regard to Palestine it is stated that the general health of the community was satisfactory, apart from the heavy incidence of enteric fever and dysentery in certain populous settlements, where conditions of sanitation and housing were bad. The estimated population at July 1, 1926, was 761,896 (excluding Bedouin). Births during the year numbered 40,721, or 53.45 per 1,000 population; and deaths 18,623, or 24.44 per 1,000. Infant mortality was 6,644 or 163.15 per 1,000 births. There were 1,400 cases of enteric fever, with 110 deaths, and 1,732 of dysentery, with 37 deaths. There has been no serious outbreak of any other infectious disease, and no case of cholera or smallpox. An intensive campaign of revaccination against smallpox was carried out in the spring, when 170,881 vaccinations were performed. The last years have seen a remarkable growth of infant welfare work in Palestine.

The number of immigrants during the year was 13,910 (6,276 men, 4,864 women, and 2,770 children), of whom

13,081 were Jews. The figures present a striking contrast to those for the year 1925, when 34,641 immigrants entered the country, of whom 33,801 were of Jewish race. The total number of emigrants during the year was 9,429, of whom 7,735 had settled in the country only since 1920. Three-quarters of the emigrants were working men and women. The volume of unemployment increased constantly throughout the year from 3,000 at the end of 1925 to 8,000 at the end of 1926.—*Lancet* 2:1425 (Dec. 31), 1927.

The Value of Prenatal Care—There were 3217 mothers delivered in the obstetrical department of the Louisville City Hospital from April 1, 1923, to July 1, 1927. Of these 1,156 had received no prenatal care at the hospital clinic. The remaining 2,061 were registered in the clinic and had made at least 1 visit. Among the 2,061 patients receiving prenatal care there were 6 maternal deaths, a mortality rate of 2.9 mothers per 1,000 deliveries. The maternal deaths among 1,156 non-clinic patients numbered 26, giving a death rate of 22.4 per 1,000 deliveries. In 1927 there were no maternal deaths among the 658 prenatal clinic patients.

Fetal and neonatal deaths calculated on the basis of the total number of deliveries show a mortality of 7.5 per cent among the clinic patients and 22.6 per cent among the non-clinic. There were 35 cases of eclampsia among the non-clinic mothers; 10 of these patients died giving a mortality of 8.5 deaths per 1,000 deliveries. Eclampsia developed in 12 of the clinic patients, due to inadequate prenatal care, but none of them died.—Alice N. Pickett. *Kentucky State M. J.*, Feb., 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Restaurant Inspection—The Bureau of Food and Drugs of the New Jersey State Department of Health has been carrying on an active campaign toward inspection of eating places within the state. Items covered by their inspections include facilities for handling and preserving all foods, methods of serving ice water, lighting and ventilation facilities, general cleanliness of the kitchen, disposal of garbage, protection against flies and roaches, cleansing of dishes and utensils and sanitation facilities provided for employes. While it is appreciated that the technic of making a really valuable inspection of food handling establishments is not simple, the inspectors of the state department are endeavoring to cooperate with local health officials in inaugurating a restaurant inspection program. A. G. Wigley and A. I. Goehrig. *Am. City*, 38:155 (Feb.), 1928. Abstr. W. L. Havens.

Avoiding Pollution by Coke Oven Wastes—Phenol or carbolic acid is a product of destructive distillation of coal, and is present to the extent of less than 0.5 per cent in the ammonia liquor which condenses out of raw coke-oven gas. In the process of lime treatment of this ammonia liquor, the phenol combines to form calcium phenolate which passes into the sewers as still waste. Subsequent action of acids and carbon-dioxide in the water reduces the calcium phenolate to phenol which in the event of subsequent chlorine sterilization of the water produces the pronounced and disagreeable chlorophenol taste.

Investigations in late years have attempted to remove the phenols prior to

the lime treatment. Two successful methods were evolved; namely, the benzol extraction method and the patented Tiddy-Hoffner or distillation method. Description of the first method is given, together with sketch of process and accompanying formula and reactions. Through operation of this benzol extraction method, the extraction efficiency has been raised over 96 per cent. More than 25,000 gallons of pure phenol are recovered yearly from the 36,000 gallons of ammonia liquor treated daily. The plant is financially self-supporting. Hugh E. Jones. *Water Works Eng.*, 81:141 (Feb. 1), 1928. Abstr. Chester Cohen.

Odor Nuisances at Sewage Works: the Use of Chlorine—Emanating from sewers and sewage plants are several different odors. Hydrogen sulphide has been shown to be the most serious of the odor-producing gases and is also destructive to masonry structures.

In odor control, prevention rather than destruction is a chief objective. The introduction of chlorine at a point where sewage is fresh is important, though frequently the sewage becomes stale before a major portion of it can be collected for treatment.

Where odor production exists, the following conditions seemingly must occur simultaneously: (1) presence of sulphates; (2) hydrogen sulphide-producing bacteria; (3) temperature sufficiently high to promote rapid growth of sulphide-splitting organisms, and (4) period of time necessary for producing hydrogen sulphide. Elimination of but one of these factors will result in securing effective control of hydrogen-sulphide generation.

Odor destruction consists primarily in splitting up the hydrogen sulphide in sewage.

Another factor in odor control is the effect of the course of the sewage, whereby an intimate mixture may be caused between fresh sewage and liquid heavily laden with hydrogen sulphide. Saving in chlorine consumption may be effected by changes in flow chambers to prevent disturbance of the lower 5 feet of liquid in the chamber. Chlorine application to the influent will effect complete odor elimination at moderate expense. On the whole, odor control is much more readily effected at separate sludge digestion plants.

In conclusion, examples are given of chlorination for odor control at Neodesha and Independence, Kan. L. H. Enslow. *Surv.*, 73:183 (Feb. 3), 1928. Abstr. H. W. Streeter.

A Comparison of the Temperature and Bacterial Count of Milk and Foam During Certain Stages of Pasteurization—This article includes a complete description of the apparatus and methods employed, including the construction, placement and operation of the thermocouples. Studies were made under conditions of normal operation at plants using the batch method of pasteurization.

Bacterial count of foam was higher in every instance than that of the milk. During pasteurization the bacterial count of milk decreased, while in 66.7 per cent of the tests the count in the foam increased. Bacterial count of foam varied greatly at different points in vats. Depth of foam did not affect bacterial reduction. If vats are tightly closed, bacterial content of foam is reduced.

The temperature of the air above the foam, and of the foam itself was in every instance lower than that of the milk. The amount of foam varied in area from

small patches to the entire surface of the vat and in depth from $\frac{1}{2}$ to 4 inches. In no case was the foam raised to a satisfactory pasteurizing temperature. H. W. Whittaker and R. W. Archibald. U. S. Dept. of Agriculture *Tech. Bulletin No. 18*, Sept. 1927, 11 pp. Abstr. C. T. Butterfield.

Controle Technique d'une Installation Municipale de Sterilisation d'eau par l'ozone. (Control of a Municipal Plant for Purification of Water by Ozone)—A description of the water disinfecting plant of the City of Boulogne consisting of an ozonizer and the circulating system for ozonized air and the sterilizer or disinfecting unit. The ozonizer consists of a series of glass cylinders, a coaxial aluminum rod which serves as one electrode and the aluminum enclosing case serving as the other electrode. A single phase, 50 cycle, alternating current transformed to 8,000-10,000 volts is applied to the electrodes. Air dried by calcium chloride is forced through the cylinders in which the silent electrical discharge occurs generating the ozone. This ozonized air is forced through a sterilizer, consisting of a vertical tower of reinforced concrete divided at intervals by horizontal partitions of perforated celluloid to insure intimate contact between the water and the ozonized air, both of which enter at the base of the tower. The effluent from the sterilizer is tested periodically with starch iodide for free ozone and in the manner used for determining the residual chlorine in water. Bacteriological data are given indicating that the number of *B. coli* per liter was reduced from 1,000 to 0 and the gelatine count was reduced from 714 to 6 per c.c. The plant, with a capacity of 10,000 gal. per hr., consumes 0.65 K.W. hrs. of current to operate the ozonizer, consisting of two units of 3 cylinders each, and an additional 1.1 K.W. hr. to operate the air compressor.

J. Salmon and P. Quarre. *Bull. Hyg.* 2:978 (Dec.), 1927. Abstr. C. R. Cox.

Colorado State Board of Health, Division of Sanitary Engineering, Laws and Regulations—This is a 34-page leaflet issued in 1927. In it appear either compilations or the text of state laws of Colorado and of the rules of the State Board of Health relating to public water supplies, water purification plants, sewer systems, sewage treatment plants, municipal garbage collection and disposal, rural and camp sanitation, swimming pools and other public bathing places, irrigation with sewage, etc., being of usual concern to the sanitary engineering divisions. The leaflet is unusually embracive, giving for example the high lights of the district improvement acts for financing sewers and water systems and the laws relating to eminent domain. Issued by Colo. State Board of Health, Denver, Colo. Abstr. C. G. Gillespie.

Cyanide Waste Poured Into Stream Poisons Livestock—Cattle died soon after drinking water from a small stream into which was discharged the effluent from an Imhoff tank, intermittent sand filter disposal plant. Investigation disclosed that on this particular day a 600 gal. vat of electrolyte, which among other salts contained 2 lbs. of sodium cyanide per gal., had been dumped into the sewer by mistake. The question arises as to what effect small amounts of this substance will have upon the bacterial flora of sewage disposal systems. A. H. Wieters. *Water Works Eng.*, 81:204 (Feb. 15), 1928. Abstr. H. E. Miller.

Spent Gas Liquor in Relation to Sewage Disposal—Spent gas liquor is dangerous to fish life and cattle and detrimental to small streams, as its oxygen absorbing qualities prevent and retard self-purification. The difficulties of dealing with gas liquor have become more acute because of: (a) the increased

manufacture of gas for domestic uses: (b) the introduction of vertical retorts with use of steam, thereby increasing the volume of gas liquors, and (c) the adoption of the activated sludge method of sewage disposal. With vertical retorts, 76 gallons of spent liquor are produced per ton of coal, whereas with horizontal retorts, 50 gallons are produced. The efficiency of the activated sludge process is likely to be affected by the presence of unduly high amounts of spent gas liquor in the sewage treated. Because of its high oxygen-absorption power, the admixture of the spent liquor with crude sewage requires greater aerobic activity in the treatment of such mixtures, usually necessitating an increased purifying area.

It is possible, by several measures named, to diminish the amount of gas liquor produced; likewise to purify the liquor before its discharge into sewers. In the latter connection, it is noted that if the volume of spent gas liquor does not exceed 1 per cent of the volume of domestic sewage, and is introduced into the sewers in a small steady flow, the mixture can be purified without difficulty. Experiments made on treatment of the spent liquor have indicated that when diluted until the 4-hour oxygen absorption value is 4000 p.p.m., the liquor itself is amenable to biological filtration, which at a rate of 15 gals. per cu.yd. per day of 8 hrs., reduced the oxygen absorbed by 90 per cent, and a second filtration at a rate of 12 gals. per cu.yd. produced an effluent absorbing less than 20 p.p.m. of dissolved oxygen.

In conclusion, it is stated that the discharge of spent gas liquors into sewers should be as far as possible uniform and proportionate to the flow of domestic sewage. The construction of equalizing tanks for this purpose offers no engineering difficulties. H. Ross Hooper. *Surv.*, 73:111 (Jan. 27), 1928. Abstr. H. W. Streeter.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH. D.

The Practical Application of Two Qualitative Tests for HCN in Ship Fumigation—This investigation was undertaken with the purpose of establishing a simple chemical test for the determination of HCN in practical ship fumigation. The importance of such a test in determining the time at which a vessel may be entered by the fumigating or the vessel crew is obvious.

The following criteria were laid down as being necessary for the test:

1. The test should be definite under all conditions, at or above the predetermined danger point to human life.

2. It should be such as can be applied without attendant danger to those making it.

3. The time factor of its reaction should be slow enough to permit of accurate computation with an ordinary watch in the hands of the usual personnel engaged in this work.

4. The test should be efficient within at least 10 per cent of error as to time.

5. The varying atmospheric conditions at seaports should not materially affect the application of the test.

Both tests herein described depend on the change in color of filter paper which has been previously immersed in certain solutions. The first test consisted in the use of benzidine copper acetate. This test is valid only where no disturbing constituents may enter the reaction; for example, such cases as chlorine and nitric acid. Study, however, revealed the fact that the reaction time was so rapid that an error of but three seconds might mean an error of 30 per cent or more in the efficiency of the test.

The second method which was studied was the methyl orange-mercuric chloride mixture. This is a color test depending on the change of color of a No. 40 What-

man filter paper, treated with this solution, to which has been added a specific amount of glycerine. On exposure to HCN gas this paper, which is an orange color, turns pink.

In conducting these tests, amounts of HCN, varying from 6.7 to 0.21 gm., were used per 1000 cu. ft. of air, and the study indicated that there is an approximate ratio between the concentration of HCN, the time of exposure, and the color of the test paper. A series of 55 comparative tests were made on 10 vessels using these test papers and white rats, in order to estimate the degree of toxicity of the atmosphere. It was found that these test papers are very satisfactory for the purpose intended.

One difficulty, however, arose, namely the maintenance and use of the test papers under certain conditions of humidity. When attention was paid to the keeping of the papers at a relative humidity of 70 to 75 per cent they were found to yield results of good practical value.

Chloro-picric acid, which is an ingredient of certain ship disinfectants, was found not to affect this test paper on six minute's exposure.—G. C. Sherrard, *Pub. Health Rep.*, 43, 17:1016-1022 (Apr. 27), 1928.

L. G.

Some Clinical and Pathologic Observations On Silicosis in Ontario—During the course of dust studies, conducted by the Division of Industrial Hygiene of the Ontario Department of Health, 1487 men were examined clinically and by means of the X-ray. Nineteen pairs of lungs obtained at post-mortem were studied and the percent-

age of silica, estimated at SiO_2 , in the ash of these lungs was determined. The silica content of the lungs was determined by digesting and igniting the lung tissue, and finally a hydrofluoric analysis of the residue. Most of the men examined were exposed to dust containing silica, a few exceptions being added as controls. The dust varied from 2 per cent to 99 per cent in silica content, estimated as SiO_2 . A discussion is presented showing the relation between the condition of the worker prior to death and the pathological findings of his lungs on autopsy. The lowest amount of silica found in this survey to be involved in the production of silicosis was from 10 per cent to 14 per cent.—Andrew R. Riddell, and H. E. Rothwell, *J. Indust. Hyg.*, 10, 5:147-157 (May), 1928. L. G.

Fatal Accidents From Electric Shock in Recent Years—From this brief committee report one may conclude that the fatality rate from electric shock in the United States (0.9 per 100,000) is somewhat higher than that for Switzerland (0.7 per 100,000), and both of these countries have rates greatly in excess of that for England and Wales (less than 0.1 per 100,000).

An interesting table is presented which shows the number of fatal accidents from low voltage circuits (110 to 550 volts). It would appear from this that low voltage circuits are definitely responsible for approximately 75 deaths for the period 1912 to 1926. The conclusion is evident that these low voltage circuits must be reckoned with in accident prevention work of this type.

The committee recommends that education of the public in precautionary measures and the importance of using only first class household equipment be urged, and that continued education of the employes of electrical industries, as well as the development of methods of resuscitation for cases of cardiac fail-

ure, be undertaken.—*J. Indust. Hyg.*, 10, 4:111-116 (Apr.), 1928. L. G.

The Problem of Automobile Exhaust Gas in Streets and Repair Shops of Large Cities—The atmosphere of 14 cities in the United States was sampled by taking "grab" samples in 500 c.c. glass bulbs. The samples were representative of the atmosphere at the breathing level of the usual pedestrian, in general some 20 or 30 feet from the street intersection, and at the time of peak automobile traffic. Other samples were taken in repair shops, and a third group in automobile busses.

The samples were analyzed for carbon monoxide by the iodine pentoxide method, using liquid air for the removal of the unburned gasoline and other interfering substances. The method probably has an accuracy of 1/10 part of carbon monoxide in 10,000 parts of air.

In all, 141 street samples were taken, yielding an average of 0.8 part of carbon monoxide per 10,000 and a range of from 0.2 to 2.9 parts per 10,000. One hundred and two samples were taken in automobile repair shops. They yielded an average of 2.1 parts per 10,000 and a range of 0.2 and 11.0 parts per 10,000. But 7 samples were taken in automobile busses. These averaged 0.5 parts and a range of from 0.1 to 1.0 parts per 10,000.

The authors conclude that no hazard exists in the automobile busses tested and that to the ordinary pedestrian no carbon monoxide hazard exists in the city streets; the police traffic officers are the only exception to this rule, and the potential hazard to these officers may be minimized by diminishing the duration of exposure. In striking contrast with these results, however, are those of the garage repair shops. The authors consider that a dangerous condition demanding serious consideration exists in these establishments. Certain precautions concerning the operation of cars in

repair shops are discussed.—J. J. Bloomfield, and H. S. Isbell, *Pub. Health Rep.* 43, 13:750-765 (Mar. 30), 1928. L. G.

Effects of Dust Upon Coal Trimmers—In the statistical portions of this paper the authors present an analysis of 426 deaths between the years 1910 and 1926, obtained from the Coal Trimmers' Union. When compared with deaths among the male population of England and Wales for the same years this material indicates that coal trimmers have a somewhat lower rate from phthisis and a distinctly higher rate from bronchitis and pneumonia than have the male population of England and Wales. Statistical evidence, calculated as percentage of deaths from certain causes of the total deaths for the years 1910-1912 for England and Wales, is also discussed, and this evidence appears to indicate that coal heavers have approximately the standard rate from phthisis, cancer and circulatory diseases, a higher rate from bronchitis, and a much higher rate from pneumonia. Comparative mortality figures for phthisis, bronchitis and pneumonia for the years 1921-1923 and for all occupied and retired males, all coal miners, and for coal boat loaders and dischargers is presented. These figures serve to corroborate the statistics previously discussed in indicating that coal miners suffered a somewhat lower phthisis rate and that coal miners and coal boat loaders suffered a greatly increased bronchitis and pneumonia rate.

Radiographs and case histories are presented of some of the coal operatives which indicate that the chests of these men are not normal, yet the authors feel that these must not be confused with the silicotic fibrosis of silica workers.

The statistics of the Coal Trimmers' Union included 51 cases of cancer. Eleven, or 22 per cent, were cases of cancer of the skin, in contrast to but 3.3 per cent of cases of cutaneous

cancer among males in England and Wales for the year 1925. The 5 cases of cancer of the skin of the neck are considered noteworthy by the authors. On the other hand, cancers of the intestines, etc., amounted to but 6 per cent, as contrasted with 23 per cent for England and Wales.—Edgar L. Collis, and J. C. Gilchrist, *J. Indust. Hyg.*, 10, 4:101-110 (Apr.), 1928. L. G.

Arsine Intoxication: A Case of Suspected Poisoning in the Steel Industry—The "pickling" of metal in acid baths for the removal of "mill scale" may lead to the production of arseniureted hydrogen (AsH_3) or arsine. The present report deals with the industrial and clinical history of a worker engaged in "pickling" sheets of rolled metal in a 5 per cent sulphuric acid bath. The worker was employed for approximately 9 months in handling these sheets of metal. A short time after he had changed his employment he complained of a feeling of tightness across the chest, difficulty in breathing, and a generalized feeling of weakness. His skin presented a scaly, peculiar bronzed appearance which grew progressively worse until he developed tremors and paresthesias of the muscles of the arms and legs, and finally complete paralysis of these members. The report presents an interesting inquiry into the various factors surrounding his work and the materials with which he was engaged, in an effort to decide whether or not the industrial environment might constitute the source of his poisoning. A 473 liter sample of air taken at a representative position in the workroom was found to contain less than 1/1000 mg. of arsine. The conclusion is reached that the man's industrial occupation was not responsible for his poisoning.—C. W. Muehlberger, A. S. Loevenhart, and T. S. O'Malley, *J. Indust. Hyg.*, 10, 5:137-146 (May), 1928.

FOODS, DRUGS AND NUTRITION

WALTER S. FRISBIE

Gassy Fermentations in Reheated or Processed Cheese Products Containing Pimentos—Manufacturers of cream cheese, loaf cheese and cheese spreads experience considerable difficulty from gassy fermentations when pimentos are incorporated in these products. Reheated or processed cheese products are particularly favorable media for the growth of bacteria. By observing certain precautions in manufacture it is possible to protect reheated or processed cheese products from contamination with gas producing bacteria from every source except the cheese itself. Contamination from this source might also be controlled and the gassy fermentation prevented if it were economically possible to use only the best quality of cheese. Inasmuch as a certain amount of cheese of poor quality is always used, the possible presence of gas producing bacteria must be accepted. Sterilization of the manufactured products is obviously impossible. By removing the fermentable carbohydrate from the pimentos an attempt was made to render the products less favorable as media for the development of the gas producing bacteria. Experiments were conducted wherein pimentos were washed in double their weight of tap water three times in 30 minutes. They were then allowed to stand in fresh water for 18 hours, rinsed in fresh water, ground and sterilized. When pimentos thus washed and sterilized were added to plain cheese spread, no gas developed. The experiments were repeated a number of times with confirmatory results. The washing which is believed to be excessive and which can probably be lessened removes some flavor

and color from the pimentos. The method has not been tried on a factory scale. The findings are applicable to all food products in which pimentos are incorporated which are subject to a gassy fermentation.—W. R. Albus and S. H. Ayers, *J. Dairy Sci.*, 11:175 (May), 1928.

Seasonal Variations in the Antirachitic Value of Sunlight—This article is a review of an address delivered at Kansas City before the Interstate Post-Graduate Medical Association by Dr. Alan Brown and Dr. F. F. Tisdall. At Toronto rats fed on a rachitogenic diet were placed out of doors from 11 a. m. to 1 p. m. daily, control animals on the same diet being kept in the dark during the experimental period. Each week throughout the year batches of rats were started under these conditions and after a month each batch was killed and examined for signs of rickets. The results showed that in Toronto even winter sunshine had slight antirachitic value, but from the end of February onward, this value increased sharply, corresponding with an increase in the shorter rays of the solar spectrum. The biological test bears very little relationship to meteorological records of sunshine during the corresponding periods, owing to the ease with which the effective rays are absorbed. A second series of experiments designed to test the relative values of direct sunshine and of "sky-shine" demonstrated that the scattered rays were from one-half to two-thirds as effective as the direct sunshine, a point of practical importance as indicating a means of applying an efficient dose of

ultra-violet rays in cases where radiant heat is undesirable. Animals exposed to light were not only protected from rickets but also showed an increased resistance to deliberate infection. The intestinal contents of the irradiated rats were found to be more acid than those of the controls, indicating a better digestion in the former.—Anon., *Lancet*, 214:715 (Apr. 7), 1928.

Pellagra-like Lesions Associated With Deficiency of Vitamin B₁ in the Rat—The experiments here recorded confirm those of Goldberger and his colleagues as to the presence of two vitamins in yeast. The presence of both factors is necessary for the normal growth of the rat. In the absence of the thermo-labile vitamin B₁ there is a failure of growth, loss of appetite and a terminal fall of body temperature with the histological appearances characteristic of starvation. There may or may not be symptoms of polyneuritis followed by death in from 4 to 6 weeks. The condition resulting from the deficiency of vitamin B₁ is very similar to that arising from vitamin B deficiency.

In vitamin B₂ deficiency there are characteristics symmetrically arranged skin lesions, together with ulceration of the tongue and buccal mucosa. The changes are very similar to those of pellagra in man. A papillomatous condition of the cardiac portion of the stomach is common in rats deprived of vitamin B₂ and in animals dying as the result of this deficiency there are found the histological changes associated with inanition.—G. M. Findlay, *J. Path. & Bact.*, 31: 353 (Apr.), 1928.

An Unusual Case of Food Poisoning—This case of food poisoning, which was found to be due to *B. aertrycke* probably transmitted in pork pie, presented certain unusual features. The poisoning spent itself on the upper

intestinal tract causing vomiting and pain but no diarrhea or signs of enteritis. There were some indications of paratyphoid fever and nocturnal rise of temperature, which is unusual in food poisoning cases. A serological investigation revealed the presence of 1:25 agglutinability to *B. aertrycke* (Mutton) and complete absence of agglutinins to *B. typhosus*, *B. paratyphosus* A, B or C, to *B. enteritidis* (Gaertner), *B. aertrycke* (Newport) and to the dysentery group. From the feces of the patient, an organism was isolated which gave cultural reactions of the Salmonella group and displayed marked flocculation in a dilution of 1:25 with *B. aertrycke* serum (Mutton type). Four days before the onset of the illness the patient had partaken of some pork pie and three other members of the household who had also partaken had suffered from slight malaise, nausea and vomiting from 1 to 3 days after this meal.—F. M. Rowland, F. W. Marshall and J. Menton, *Brit. M. J.*, 3506:439 (Mar.), 1928.

A New Differential Medium for the Paratyphoid Group—The authors devised a new culture medium for differentiating members of the paratyphoid group. This medium has the following composition.

Agar	0.20 gm.
Distilled water	1000 c.c.
Alcoholic solution of phenol red (0.2%)	12 c.c.
Difco peptone	10 gm.
Sodium potassium tartrate (Rochelle salts)	10 gm.

The medium used should be adjusted to a pH of 7.6-7.8 and is best used in tubes, unslanted, a stab inoculation being made. Observations should be made at 24 and 48 hour intervals, although the reaction in tubes is generally stable, for at least 7 days. The paratyphoid strains that impart an acid reaction to the medium give a distinct yellow color in the lower portion of the

tube, with a surface zone of from 4 to 7 mm. which remains red, while those strains that produce an alkaline reaction give a diffuse homogeneous reddish coloration. *B. aertrycke*, *B. enteritidis*, *B. suispestifer* and *B. abortivo-equinus* gave acid reaction in this medium while alkaline reaction was produced by *B. schottmülleri* and *B. paratyphosus A*. Attempts to devise a plating method with this medium were only partially successful. In the experience of the authors this medium has given a perfectly definite differentiation with a large number of strains (87 *B. aertrycke*, 45 *B. schottmülleri*) previously identified by the agglutinin absorption method.—E. O. Jordan and P. H. Harmon, *J. Infect. Dis.*, 42:238 (Mar.), 1928.

The Vitamins of Commercially Concentrated Orange Juice—In a previous investigation it was shown that 5 c.c. and 10 c.c. of fresh ripe California orange juice were doses adequate in vitamin A and vitamin B respectively for the requirements of the albino rat. Using the same breed of animals and an identical technic, a product prepared from the juice of the same species of orange by concentration *in vacuo* was found to meet the nutritive needs of the animals as regards vitamin A and vitamin B at the same level in each case. The two investigations were run in close succession and the conditions of experiment were maintained as far as possible identical. It can be concluded that the content of vitamin A and vitamin B of fresh ripe California orange juice survives the industrial process of concen-

tration by the method of vacuum distillation at 37°C. without apparent loss, at least in the case when the resulting concentrate is of fairly recent manufacture. From a review of the literature the author states that vitamin C also is preserved without loss when orange juice is concentrated at a low temperature *in vacuo*.—S. G. Willimott, *Biochem. J.*, 2, 22:535, 1928.

Iodine Content of Some Water Supplies in Goitrous Regions—The following determinations of iodine in drinking water of goitrous regions are uniformly low, except in the case of Lasalle, Ill. Lasalle has two water supplies. It is stated that there is less goiter among those persons drinking water from these drift wells than the other source of supply, not analyzed.

Source	Iodine (parts per billion)
Litchfield, Ill. Impounding Reservoir	0.17
Chicago, Ill. Lake Michigan	0.13
Peru, Ill. Rock Wells (1300 ft)	0.31
Peoria, Ill. Drift Wells	0.15
Lasalle, Ill. Drift Wells	18.00
E. St. Louis, Ill. Mississippi River	0.29
Champaign-Urbana, Ill. Drift Wells	1.01
Murphysboro, Ill. Big Muddy River	0.30
Springfield, Ill. Direct from wells	0.50
Springfield, Ill. Filtration Galleries	0.52
Duluth, Minn. Spring	0.014
Grantsville, Utah	1.33

—Gertrude H. Beckwith, *Proc. Soc. Exper. Biol. & Med.*, 25:117 (Nov.), 1927.

CHILD HYGIENE

MERRILL E. CHAMPION, M.D.

Emotional Factors in Nutrition Work With Children—Both the metabolic stability and the action of the gastrointestinal system are closely allied to and seriously affected by the emotional state of the individual.

In a group of malnourished children studied at the Institute for Juvenile Research, the condition in some cases could be traced to the presence of organic or functional disease, in others to food inadequate in kind. A third group remained in which neither of the aforementioned causes could be found but rather, a definite emotional disturbance which was interfering with the nutrition. Causes of such neurotic tendencies may be traced to very early influences. The period of nursing even is a formative one and should therefore be so controlled that the child acquires not only the proper attitude toward feeding but also the proper habit training. With a lack of such discipline, which indeed requires forethought and understanding on the part of the parents, a child with definite neurotic manifestations will be the result, a problem much more difficult to cope with as the child grows older and which may, eventually, for treatment lead to the necessity of a temporary separation of the child and the parents. In a nursery school or in a hospital where the child has the opportunity to eat with and imitate others of his age there is less tendency for him to demand his own way. He will act with the group.

The method of preventing and overcoming the type of problem discussed, that is, the child malnourished because of emotional disturbances due to environmental conditions, is by means of preventive pediatrics and mental hygiene. —Emotional Factors in Nutrition Work

With Children, George J. Mohr, M.D., *Mental Hyg.*, XII: 2 (Apr.), 1928.

Mental Hygiene Even for the Feeble-minded—"On this whole problem of feeble-mindedness we are tarrying too long on the bridge of mental levels with its I. Q. buttresses. It is time that we crossed over to the other side into the less definite but far more interesting and practical realm of this problem," thinks Dr. George L. Wallace, widely known in this country for his work with the feeble-minded and for his administrative success with the School for Feeble-minded at Wrentham, Mass. He feels that in our worry about the I. Q. and mental levels we often fail to see the feeble-minded problem as it really is; in other words, that we overlook the fact that we are dealing with a condition and not a theory. The problem with the moron is lack of social adjustment. This is proved by the fact that we daily see many morons in a community without recognizing them because they have managed to adjust themselves adequately. Intellectually lacking, they react normally to their environment. On the other hand, those who do not react normally react quite similarly to those who, as Wallace says, make trouble on the higher mental levels such as pathological liars, thieves, neurasthenics, etc.

This being the case, the ideas expressed in the article in question indicate that there should be something more done than diagnosing mental retardation and creating special classes for the education of children at low mental levels. It is equally important that there be application of the principles of mental hygiene in connection with special class work so that many children other-

wise liabilities may be adjusted to their environment in childhood and so avoid becoming social failures in adult life. This program, of course, would go hand in hand with one for increasing facilities for the institutional care of the feeble-minded in need of it.—George L. Wallace, M.D., *Mental Hyg. Bull.*, Apr., 1928.

Practicing What They Preach—Very practical inducements are offered by the Vassar Brothers Hospital in Poughkeepsie, N. Y., to prospective mothers to get adequate prenatal care. This hospital has set aside the entire third floor for maternity work and offers to prospective mothers of the community a flat rate of \$65 for all semi-private patients whose prenatal care has been adequate. This charge includes all laboratory examinations made at the hospital, use of the delivery room, and board and care of the mother and baby, regardless of the length of stay in the hospital. The only requirement is a record of prenatal care. A further statement is made that for ward patients a flat rate of \$35 is offered on a basis similar to the above, with the possibility that those unable to meet this charge can have a still further adjustment.

Poughkeepsie is evidently spurred on to this highly constructive step by the fact that their maternal death rate is 63 per cent higher than that for the entire state and their infant mortality rate is 46 per cent higher. They are relying upon the prenatal care to produce a change in this situation and feel encouraged in that belief by the work accomplished by four public health nurses in Tioga County which apparently was responsible, in part at least, for a reduction in the mortality amongst mothers and children cared for.

A further commendable step has been taken by the hospital in sending to each of the 125 members of its staff a copy of *Standards of Prenatal Care* (supplied

by the New York State Department of Health) and record forms for patients.—*Health News*, Apr. 16, 1928.

The Infrequency of Severe Rickets In New Orleans And Vicinity—One of the interesting facts concerning rickets is its variation in occurrence throughout the different sections of the country. Forbes and Green found the incidence of the disease to be 25 per cent in Denver in 1925; Morse found it to be 80 per cent in Boston in 1900. From New Orleans, where the average is 45 per cent among children 3 years old or less, Dr. Williams reports a study of 100 children where an effort was made to determine if possible reasons for the comparatively low percentage in that vicinity and any other conditions pertinent to the knowledge of rickets as a disease.

Over a period of a year, it was found that there was a seasonal variation in the content of inorganic phosphorus in the blood of the group as a whole; that most of the calcium readings were normal while the inorganic phosphorus was low in every case of diagnosed rickets. There was a direct correlation between the inorganic phosphorus content of the blood and the possible sunshine for each month. Among the breast-fed infants, there was a lower incidence of rickets with a definite relationship to the health of the mother and to the nutrition and the care given herself and the baby. Of the breast-fed infants who developed rickets, of which there were 3, 2 were being nursed by mothers who did not eat green vegetables. Among the 100 children studied, 26 per cent had rickets.

The conclusion formed is that because of its geographical location New Orleans is able to report not only a low percentage of rickets but also a mild form of the disease.—The Infrequency of Severe Rickets in New Orleans and Vicinity, C. T. Williams, M.D., *Am. J. Dis. Child.*, 3514, Apr., 1928.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Field Training for Health Services—The East Harlem Nursing and Health Service, through the generosity of the Milbank Memorial Fund, now offers educational experience and field training to qualified nurses and other workers in the health field.

A full-time supervisor of student activities will direct the field work of the students in coöperation with the general supervisors of the nursing staff and the special supervisors of nutrition work, health education, psychiatric social work, research and statistics.

An advisory committee on the educational program, appointed by and responsible to the Governing Board of the East Harlem Nursing and Health Service, has been named. The membership of the committee, which includes representatives from the fields of education nursing, medicine, nutrition, social work and statistics, gives assurance of the broad scope of the teaching program and promise of interesting developments in the correlation of allied services in the health field.

Application for field training or observation will be considered in the light of the candidate's past experience and future plans.

Teachers College is actively interested in the teaching program, and will participate through the Departments of Nursing Education and Nutrition.—East Harlem Nursing and Health Service, 354 East 116th Street, New York, N. Y.

The Nursing Shortage—The preliminary work of the Committee on the Grading of Nursing Schools has brought to light some interesting facts regarding

the alleged nursing shortage. In fact, it found the shortage to be non-existent. On the contrary, the evidence points to an over supply of nurses as far as gross numbers are concerned.

Whereas there were but 15 nursing schools in the United States in 1880, there were 2,155 in 1926, which added, and are adding yearly, 18,000 graduates to the nursing profession. Many of these drop out of professional life early, but at least half remain for eight or more years.

Old schools are growing, new schools are springing up, sickness is going from the home to the hospital, cases are shorter, people in the United States are in better physical condition than ever before. Yet, at the same time, there are many calls which go unanswered. In the face of these facts, what is in the future for the nurse?

Three solutions to the situation have been proffered. The first is that the nursing schools should exclude any applicant who does not give reasonable promise of becoming an ethical and competent nurse. The second is that the nursing profession, especially that part concerned with private duty nursing, endeavor to keep track of what its members are doing and to try to put each into the place for which she is best adapted. The third suggestion is that an effort be made to work out a more flexible nursing service with different degrees and qualities of nursing care at different costs for different periods of time. Such a service would need to acknowledge that all nurses are not of the same value and that cases vary in importance and difficulty. Assignments, hours, and pay should be adjusted to meet these facts.

A reorganization in private duty nursing along these lines, to be at all successful, needs the sympathetic and intelligent support of the medical profession.—May Ayres Burgess, Ph.D., *The Nursing Shortage*, *J. A. M. A.*, 90, 12: 899 (Mar. 24), 1928.

The Truth About Insulin—Dr. Hobart Rogers answers simply and graphically some of the questions which we hear repeatedly with regard to insulin.

1. Is Insulin a Cure? Insulin is not a cure in the sense that it will restore diabetics to perfect health, but its use can restore many diabetics to such a degree of health that they may dispense with its use.

Diabetes is a disease of assimilation in which sugars are not properly utilized but are allowed to accumulate in the blood and pass out, unused, in the urine. Insulin is a substance produced by the pancreas gland which is necessary for the proper assimilation of sugars. All of us have insulin all the time, produced within ourselves. A defective or diseased pancreas, which cannot produce insulin, causes diabetes. The treatment consists of giving the patient insulin extracted from the pancreas glands of cattle.

In many diabetics, the pancreas is not really destroyed but merely exhausted from overwork, and, if relieved of overstrain for a time, it may recover to such an extent that insulin treatment will be no longer necessary.

2. If One Begins its Use Must He Not Always Continue? "Any diabetic who is taking insulin may discontinue its use and return to the old methods any time he chooses." Some diabetics continue to need it while others prefer to take it because of the salutary effect it has upon them. Under insulin treatment, sufficient food may be eaten to enable diabetics to maintain their nor-

mal weight and do hard work; while without insulin so little food is allowed that they are thin, starved and melancholy, never able to do a day's work.

Diabetics who do not take insulin are always made very ill by colds, tonsillitis and pneumonia. The two most dreaded complications are diabetic coma and gangrene which often follow intercurrent diseases and sometimes end fatally. A diabetic properly treated with insulin is in no more danger of acute diseases than a normally healthy person.

3. Is not the Use of Insulin a Great Inconvenience? The treatment and the hypodermic injection once or twice a day are both inconveniences, but, if they are accepted as part of the day's routine, they can be made as commonplace as dressing, bathing or shaving.

4. Is There not Something Just as Good That Can Be Taken By Mouth? There is nothing as good as insulin. It is a purely physiological product with an absolutely harmless action. The preparation called synthalin can be taken by mouth, but its effects are feeble and it can be used only in the mildest cases. Furthermore, it is a drug.

CONCLUSION

Insulin is not a cure but a perfect means of control, capable of producing great improvement.

The benefits derived from its use greatly outweigh the inconvenience of administration.

No more conveniently administered substitute has yet been found.—Hobart Rogers, M.D. *The Truth About Insulin*, *Pacific Coast J. Nurs.*, XXIV, 4:204 (Apr.), 1928.

Nursing Situation Surveyed in Queens—How adequate is the supply of public health nurses in Queens? Under what auspices do they work and what is the scope of the work done by each?

The answers to these questions will be found in the report of the nursing situation in the Borough of Queens which was recently undertaken by the Welfare Council of New York City. The Committee, appointed by the Public Health Nursing Section of the council, has submitted its report to the Executive Committee of the council and prompt action is to be taken upon the recommendations.

Frederika Farley, chairman of the committee, states in the report that there is need of three times as many public health nurses as are now available in the borough. Ten times as many nurses are needed in the particular fields of infant welfare and tuberculosis. To provide for an adequate maternity service, Queens requires fifteen times as many nurses as it now has.

The scarcity of public health nurses would present a critical situation in the event of an epidemic, for in a borough of one million people there are only 131 nurses. Of these only 71 are available for the community at large. The report further states:

The critical nature of the situation is illustrated by the following facts, revealed in our survey: with 2363 known cases of tuberculosis in the borough, and 3544 "contacts" or other persons living with those having tuberculosis, as well as for all other communicable diseases, there are only 24 where at least 60 are needed; in the field of infant's health 6 nurses are on duty and 60 are needed; in the maternity field, in this borough which had 12,925 births last year, 2 public health nurses are available

where 30 are needed; in the schools of Queens with 149,000 pupils, 27 nurses are on duty and 68 are needed; in the field of bedside care 47 nurses are available and 182 are needed.

The committee found that no instruction in "Home Hygiene and Care of the Sick" is being given in Queens except by 4 nurses of the Department of Education in 4 high schools.

RECOMMENDATIONS MADE

The report of the Public Health Nursing Survey Committee makes the following recommendations:

The Committee suggests that inasmuch as all the nursing organizations in Queens, except 3, are working on a borough basis, that the nursing work be organized as a borough activity rather than a community activity.

That the Red Cross Chapters promote classes in "Home Hygiene and Care of the Sick."

That, if possible, the public health nursing work in Queens Borough be developed as a generalized program rather than a specialized program, but if this is not feasible to begin with:

That the first additional nurses be assigned to duty in the bedside group putting special emphasis on the necessity of increasing the complete maternity service;

That additional nurses be added to the other groups as rapidly as possible, and that, as soon as practicable, there be one nurse director for the public health nursing work in the Borough;

That this report be submitted to the Welfare Council by the Public Health Nurses Section with the recommendation that the Welfare Council present the report to the public-spirited people of Queens Borough;

That the Welfare Council appoint a committee of interested people of the borough to promote plans whereby this increased nursing service may be developed as soon as possible.

Long Skirts at an Annual Meeting

—In the 30th annual meeting of the Victorian Order of Nurses for Canada, Montreal Local Association, there was featured a

. . . five-minute scene depicting the nursing visit 30 years ago, and one depicting the nursing visit today, which struck a new note in annual meetings for Montreal. The voluminous skirts of the gay 90's, the lack of social organization with a consequent lack of coöperation, the

old-fashioned cradle continually rocking, were in striking contrast to our short-skirted brisk nurse of today, with all sorts of social organizations ready to help her, no cradle but a crib for baby, and occupational therapy for grandma who used to sit buddled in a chair all day with folded hands gradually becoming stiffened. The scenes were short, and the dialogue very much to the point, with enough humor to embellish it.—

Genevieve L. Hurd, Executive Secretary.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

New York Studies Its Health Education Material—The readers of this department will be interested in knowing that a study of the variety and extent of the use of various materials and methods in health education by a selected group of agencies is under way in New York City. Later we hope to be free to announce the publication of a report on this study which is being made by Janet Jarrett representing the Research Bureau of the Welfare Council of which Neva R. Deardorff is director.

Give Them a Chance—Give the actual publicity workers in your organization a chance to get ideas and inspiration from attendance at the Annual Meeting in Chicago next October. No one is so skillful and resourceful in the spreading of health information that he will not gain greatly from attendance at the Chicago meeting. Nothing can take the place of personal contacts and conferences with workers in the same field. Better to cut down the expenditure for printed matter or other publicity and education budget items than to have your actual publicity worker stay at home.

"No—But—"—Here is what Prof. Harry A. Overstreet said at a recent luncheon of the New York Committee on Publicity Methods about a cancer folder: "'Have You a Cancer?' it asks in large black type all over the first page. I don't like the idea—'No!' I retort mentally, and toss the folder into the waste basket. But my wife picks it up and looks inside. 'But this is interesting!'

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

she commented, 'I didn't know cancer had symptoms, and—see, there is a cancer age!' Now the outside of that folder was not interesting. It got the 'No!' response, which is fatal to appeal literature. But the inside was positively exciting. If the writer had raised a different kind of question on his front page, if he had asked, 'Do You Know the Symptoms of Cancer?' he would have drawn from me the 'No—but . . . ' response which would have carried me over into the substance of the appeal. Don't forget that the 'No' response is fatal to interest, the 'No—but . . . ' response is stimulating to interest. But no interest will survive a long and labored introduction. Get on with it—don't spend so much time getting ready."—*Better Times*, 151 Fifth Ave., New York N. Y. Jan. 2, 1928.

Interest! Instruction!! Action!!!
—The three-fold job of the health educator or propagandist:

(a) The interest of those to be instructed must be borne in mind; their attention must be arrested, desire must be created, and self-regard must be stimulated. A commercial advertiser studies the psychology of the crowd and seeks to touch the elemental instincts of the individual. His aim is to amuse, or to give pleasure, or to instill fear into the mind of his client. He visualizes for him something which he has not hitherto seen, or calls out into exercise such imaginative faculty as he possesses. We can all think of advertisements which stick in the memory because the advertiser, understanding our psychology, has impressed upon us something which we cannot forget, even if we would.

(b) Having thus aroused interest, the propagandist must fix or anchor it by instruction, by providing a body of knowledge, concrete, correct and timely, attractively presented in very varied form, appealing to both eye and ear.

(c) Finally, also like the good advertiser, he must get action. The advertiser wants people to buy his wares: the propagandist wants to obtain from his clients assent to his advice, a practice and a mode of life.—

Public Education in Health. "A Memorandum addressed to the Minister of Health." 1926. British Library of Information, 44 Whitehall St., New York,

EDUCATIONAL MATERIAL

The revised series of pamphlets and other publications of the American Heart Association, in course of preparation, have been classified as follows: (a) those for the workers, including physicians, nurses, secretaries and others; (b) those for the patients and their families; and (c) those for the general public.

Health—Diseases, Drugs and Sanitation. List of publications relating to these subjects. Revised. Superintendent of Documents, Washington. Price List 51. *Free.* New editions mailed as issued—if requested.

Safeguarding Your Health from Tuberculosis. Department of Health, New Haven, Conn. Well done 24-page pamphlet explaining to citizens "How New Haven Cares for Tuberculosis" through public and private agencies. A form of reporting the work being done.

The 50 million dollar welfare bond issue to be voted on in Pennsylvania in November is responsible for four 6-page folders issued by the Pennsylvania Mental Hygiene Committee of the Public Charities Association, 311 South Juniper St., Philadelphia, Pa. The copy is good, and the form is a good example of the better grade of quite inexpensive folder for widespread use. Of course the type should be larger, but the leading makes it quite readable. Each of the series is on a different color of paper. The titles are: *Salvaging the Feeble-minded, Handicaps of Epilepsy, Why So Many Go Insane, Do You Know?* Samples *free.*

A handy manual of 16 pages, *Health*

for the Family, tells the residents of Bellevue-Yorkville district, New York City, of the clinics and services available. Page by page a type of clinic or service is described, with days and hours. Very well done—except that the map might better have been an inch wider to gain in clearness and usability. Address Bellevue-Yorkville Health Demonstration, 325 East 38th St., New York, N. Y. *Free.*

An educational campaign against rickets conducted by Mulberry Health Center, 256 Mott Street, New York, N. Y., produced a series of exceptionally good 1-page leaflets, an 8-page pamphlet, and four posters (one of which is not so good). A sample set for \$1.50; set of leaflets, 10 cents; posters, 40 cents each. Special rates for quantities. Ask for Plans for a Campaign Against Rickets. See reproductions in *Trained Nurse*. January, 1928. A brief account of the campaign in *Public Health Nurse*, March, 1928.

Groceries as Nutrition Educators—Going out after the coöperation of a particular group is well illustrated in the grocery store window project of the Syracuse Department of Health and Syracuse Health Demonstration. In an elaboration of the following paragraph at a meeting of the Committee on Publicity Methods at Memphis, Miss Bache brought out how by enlisting a few stores an object lesson was provided to use in getting more of them to coöperate. At one stage of the effort in Syracuse the canvass of stores was developed by districts where the cumulative effect was good both upon the storekeepers and the public.

Syracuse has been using for the past year its grocery store windows to give out nutrition lessons. Each week ten grocery stores had a new display in which health and nutrition played the leading rôle. To make the exhibits attractive, painted beaver board figures were used illustrating the subject under discussion. At the same time the exhibit was displayed in

the window, the grocers gave out printed sheets bearing the nutrition lesson outlined by the Department of Health. Some of the subjects chosen for window displays and nutrition lessons were The Child's School Lunch, Food for the Working Man, What Should Go in the Housekeeper's Market Basket? Dairy Products which make for Health, and Vegetables on the Family Dining Table. The large grocers who did some advertising saw the advantage of the exhibits at once, but the small corner grocery storekeepers had to be won. It was with them that perhaps our greatest victory lay, for many of them became sold to educational advertising and much helpful information was gotten over not only to the consumer, but the merchant.—

Louise Franklin Bache.

SCHOOLS AND CHILDREN

How it came about that in Athens, Ga., the children "who needed to have teeth filled, pulled or cleaned, actually had them filled or pulled or cleaned," is told in A Plan with Teeth in It, by Slaughter and Smith. *Hygeia*. Dec., 1927. A reprint *free* from Child Health Demonstration Committee, 370 Seventh Ave., New York, N. Y.

Health in Drama, Verse and Song. Tuberculosis Society of Detroit, 51 Warren Avenue West, Detroit, Mich. For teachers. Out of print but will be reprinted if enough orders are received at 25 cents a copy.

Jack O'Health and Peg O'Joy by Herben (primary grades), and Most Wonderful House in the World by Haviland (middle grades) are recommended in Books for the Rural Schools in the Southern mountains, by *Mountain Life and Work*, Berea, Ky.

The Jolly Jester, by Harvey W. Wiley. *Good Housekeeping*. Jan., 1928. "Here is a clown spreading the gospel of good health most convincingly."

May Day suggestions for the whole community are given in A Festival Book of May Day—Child Health Day. 1928. 80 pages. Illustrated. American Child Health Association, 370 Seventh Ave., New York, N. Y. 10 cents. The May Day plans may be adapted to "Play

Day" at a later date in communities where May Day was not observed.

Long Life to Your Children's Teeth (18 pages); The School Lunch (32 pages). Educational Department, Postum Company, Battle Creek, Mich. *Free*.

TITLES

False Dentists and False Teeth—*Hygeia*.

The Old "Spring Tonic" That Stood on the Shelf—Oregon State Board of Health.

Don't Buy Spectacles and Tinware Together—*Northwestern Health Journal*. April, 1928.

Slenderizing—New York State Department of Health. News release and radio talk.

The Sneeze Versus the Job.—Woman's Bureau, Washington. Press release 621. Paragraph on "common colds."

The lost 16,000—*Child Health Bulletin*. March, 1928. "The loss each year of about 16,000 mothers in childbirth."

Thousands of Hunters Trail Deadly Tuberculosis Germ—*Northwestern Health Journal*. April, 1928.

Are You Digging Your Grave with Your Fork?—Title of a pellagra folder by Health Conservation Department, Pilot Life Insurance Company, Greensboro, N. C.

This Is No April Fool!—A folder on smallpox distributed by the local gas and electric company. Prepared by Racine Board of Health.

The Road to Happy Motherhood—Milwaukee Health Department. 40 pages. Excellent "mother book." Not simple enough for some groups.

Slender Youth—a Pilot Life Insurance Company (Greensboro, N. C.) folder. Some of the sub-titles: Youthful Lightweights Are Bad Risks, Fashion-Plate Girls May Be Walking Sanitarium Ads, A Big Breakfast Starts the Day Right.

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

Triumph Deferred—Eight measures which had been adopted by Congress and presumably represented the will of the people were vetoed by President Coolidge about the middle of May, 1928. One of these was the Parker Bill for federal health coördination; another was a bill allowing retirement privileges under certain conditions to emergency officers of the World War, including many medical officers.

Congress showed its regard for the Presidential disapprovals by promptly repassing by overwhelming majorities three of the vetoed measures, including the emergency officers' bill. Unfortunately, no action was taken again on the Parker Bill before adjournment of the session.

The reasons given by the President for his strange action in vetoing the Parker Bill were that it tended to "militarize" the U. S. Public Health Service and that one part of it was unconstitutional. To support this latter contention he quoted from an opinion of the Attorney General to the effect that the bill limits the choice of presidential appointees to persons who pass an examination conducted by a board convened by the Surgeon General and also limits the choice to persons who are recommended by the board and the Surgeon General. The Attorney General seems to think that such action vests in the Surgeon General improper participation in the executive functions of the government.

With regard to the U. S. Public Health Service as a military organization, the U. S. Court of Claims held on April 30, 1928, in the case of Rupert Blue v. U. S. that it is not a military

body. In that case former Surgeon General Blue was denied exemption in his income tax claimed for the years 1918 to 1920 on the ground that the U. S. Public Health Service was part of the military forces. The Parker Bill does not cause any further militarization of the U. S. Public Health Service, but simply provides that sanitary engineers and certain other scientists be given a commissioned status similar to that of the medical officers. This provision has always been ardently opposed by H. M. Lord, Director of the Bureau of the Budget, one of the President's close advisers.

The article of the Constitution which the Attorney General seems to think is contravened by the Parker Bill states (Section 2), ". . . the Congress may by Law vest the Appointment of such inferior officers, as they think proper, in the President alone, in the Courts of Law, or in the Heads of Departments." It is pretty far fetched to say that the Parker Bill is invalid under this clause, inasmuch as the system approved by law in 1889 (25 Stat. L. 639) and never held invalid is merely extended to cover additional personnel.

In concluding his message on this matter the President stated, "The other provisions of the bill have my entire approval, and if the unconstitutional feature should be removed and the militarization feature should be removed I should be pleased to approve it." What needs to be removed is the baneful influence of the Director of the Budget. He and Senator Smoot seem to be having the last laugh, but triumph for public health is only postponed, not prevented.

Congress Adjourns—The First Session of the Seventieth Congress adjourned on May 29, 1928, after making a better record from the standpoint of public health legislation than has been the case for some years.

In addition to passing the Parker Bill, Congress adopted a public resolution designating May Day as Child Health Day. In passing the new revenue measure, Congress voted not to increase the tax from \$1 to \$3 on physicians who dispense narcotics, in spite of vicious attacks made on the medical profession by Senator Smoot. Provision for deduction on the income tax report of traveling expenses for attending professional meetings was adopted by the Senate in considering this bill, but did not survive in conference.

Progress was made on a number of other public health measures. Thus, the Ransdell bill (now S. 4518) for a national institute of health was reported in the Senate. Copies of the hearings on this measure are now available and may be obtained from the Senate Committee on Commerce. A bill for the investigation of cancer (S. 3554) passed the Senate on May 18, as did also a bill (S. 3936) to regulate the practice of the healing art in the District of Columbia, on May 29. A similar bill (H. R. 12947) has been reported in the House.

The bill to establish two federal narcotic farms (H. R. 13645) passed the House on May 21, while the measure to amend the definition of oleomargarine (H. R. 10958) was reported on May 11. A bill (H. R. 11981) relative to service of officers of the Medical Corps passed both branches of Congress, in spite of the customary comments by Senator Smoot. A bill to regulate the sending of poisons through the mails (S. 3127) also passed the Senate, on May 10.

In connection with medical matters, there is a new veterans' hospitalization law, carrying an appropriation of \$15,-

000,000. Another new law extends medical and hospital relief to retired officers and enlisted men of the Coast Guard. Congress voted the pay and allowances of a colonel to the major who now serves as the President's physician.

New Bills in Congress—Among the nearly 20,000 bills introduced so far in the 70th Congress are a number of other new ones of interest to sanitarians. These include: H.R. 13902 for examinations for the criminally insane; S.4463 for a children's tuberculosis sanatorium in the District of Columbia; H. J. Res. 309 calling upon the President to issue a proclamation every year designating the first week in May as national health week; H.R. 13854 to provide facilities for emergency medical care at the Capitol; and S.4478, to prohibit use of public funds for purchase of butter substitutes for government wards.

All of these measures and a few others pertaining to public health, as previously reported in this department, will be before the second session of the 70th Congress when it convenes next December.

Erudition in the Appendices—The body and appendices of the May numbers of that preceptive magazine, the *Congressional Record*, have some of the aspects of a textbook on public health, for they contain the following didactic articles: Poison in Denatured Alcohol and Modern Views Concerning the Use of Alcohol, by Representative William I. Sirovitch, May 16 (page 9267); Cancer-Humanity's Most Deadly Scourge, by Senator Neely, May 18 (page 9393); Prevention and Cure of Tuberculosis, by Dr. J. Morrison, May 23; Noguchi, by Representative Sirovitch, May 24 (page 10005); Filibuster and Health, by Senator R. S. Cope-land, May 26 (page 10412); Federal

Maternity and Infancy Act, by the League of Women Voters, May 29 (page 10703).

Federal Narcotic Act Sustained—The constitutionality of the Harrison Anti-Narcotic Act of 1914, as amended in 1918, was sustained by the U. S. Supreme Court in the decision of *Nigro v. U.S.*, handed down on April 9, 1928. The case had gone to the Supreme Court by certificate of the Circuit Court of Appeals of the Eighth Circuit, with a request for answers to four questions. The Supreme Court answered only the first and second, which dealt with the meaning and scope of the word "person" in the first sentence of section 2 of the law, and with the general constitutionality of the act.

The second section of the Harrison law makes it unlawful for any person to sell, barter, exchange, or give away narcotics except in pursuance of a written order on a form issued by the Commissioner of Internal Revenue. In this case *Nigro* unlawfully sold morphine without such written order. The question was whether the words "any person" in the section were limited to those persons who are required to register and pay the tax. The answer of the Supreme Court was "No."

The law was upheld as a valid taxing measure, designed primarily for the purpose of raising revenue. The Court points out that merely calling a law a tax measure does not necessarily make it so, and cites the Child Labor Tax Act, which was held to be unconstitutional. The tax under the antinarcotic act amounts to about a million dollars a year, which is a substantial sum and a real source of revenue to the federal government.

England Has Its Troubles—American health officials are not the only ones who are sometimes unable to secure re-

ports of tuberculosis on time. According to a note in the *Lancet* for May 19, 1928, complaint has been made by the Medical Health Officer of Carlisle that physicians delay in notifying of cases of tuberculosis. There was considerable debate by the health committee as to whether to prosecute or not and it was finally decided to send another warning.

Miscellaneous items—The national narcotic drug situation today is outlined by L. G. Nutt, U. S. Deputy Commissioner of Narcotic Prohibition, in *Pennsylvania's Health* for May-June, 1928.

The White Slave Traffic Act can be violated by transportation in a privately owned automobile, according to *Holden v. U. S.* 23 Fed. R. (2d), 678.

More than a million animals were given the tuberculin test in the United States during March, 1928, according to the U. S. Bureau of Animal Industry. The number of reactors was 27,999. The number of cattle in accredited herds is over 2,000,000, and 20,500,000 more are under supervision.

The question has been asked as to what supervision is exercised by states over professional blood donors. If any reader can answer this, enlightenment would be appreciated by the Associate Editor.

"The Law Says"—All persons are presumed to know the law, but the written law is so extensive these days that it eludes even the lawyers, though they have the advantage of knowing where to look for it. In the *Commonwealth* of the Massachusetts Department of Health for Jan.-Feb.-March, 1928, Merrill E. Champion, M.D., contributes a short article about the laws in that state which apply to public health. This is useful information for local health officials as well as for laymen, and the type of thing which could appear to advantage in many state health bulletins.

BOOKS AND REPORTS

Health and Wealth—*A Survey of the Economics of World Health*—By Louis I. Dublin, Ph.D. Statistician, The Metropolitan Life Insurance Company, New York, N. Y. New York: Harper, 1928. 361 pp. Price, \$3.00.

This book is a collection of essays which have been given by the author during the past few years. Although they consider a number of different subjects, they cover phases of public health which are necessary for clear understanding of public welfare and the practical application of our knowledge. They treat largely of vital statistics, a subject on which too many health officers and physicians are deficient, and show how such knowledge can be applied in carrying out better programs. The lesson that life and health are our greatest possessions is stressed, and while it is recognized that a value cannot be put upon life solely in terms of dollars and cents, it is clearly shown that the rearing and education of a child costs money, and that the early death of an educated citizen is a financial loss to the community. Such facts are useful to all who are concerned in public health work, and especially to those who must deal with legislative bodies, to whom the economic side of health must be demonstrated.

Any country with a low standard of health is a menace to its neighbors, especially in these days of rapid transit, and international health service is one of the foremost factors in creating an understanding between nations and cementing friendship. "For none of us liveth to himself, and no man dieth to himself."

A strong plea is made for more liberal expenditures in health work. As far as children go, the loss from illness is more than the amount which good care would

cost, and from death the loss is more than ten times as great.

It is difficult to say which of these essays is most important. We must call attention to the one on heart disease, since at present it is far in the lead of all other diseases as a cause of death, while tuberculosis, which was called only a short time ago "Captain of the Men of Death" has dropped into the fifth place.

Another particularly interesting and timely essay is on "Birth Control and the Population Question." The author shows that our annual increase is only about half of what has been generally claimed and holds that all forecasts must be revised in view of our declining fecundity. We are very near the danger line of a stationary population. In view of this, the widespread propaganda for birth control is out of place, especially since it is universally practiced among those who are best fitted to become the parents of future generations. A dig is taken at the "Nordic Myth," the author holding that when the upper and lower 10 per cent of our population are eliminated, there is little indication of marked differences in ability among the intermediate 80 per cent who form the bulk of our plain folk carrying on the work of the world.

In close relation to this topic is the changed status of women, which is considered a "major revolution in the history of the world." In 1920, more than 8½ million women were gainfully employed, less than 2 million of whom were married. Of a million professional women less than 125,000 were married, and experience has shown that the greater number of them will remain single.

We wish space permitted a longer review of this unusually helpful book.

The author has the faculty of making figures interesting even to those who lack talent in this respect. He holds a position which brings him into constant contact with the problems which he discusses. For life insurance companies a correct knowledge of such subjects is essential to success. We know of no one who has taken better advantage of his opportunities than the author. He has given us a book with which every health officer, health worker, and statesman should be familiar, and which will interest all who are concerned in the welfare of humanity and the future of the race.

The make-up of the book is beyond criticism, the paper is light, yellow tinted, with a mat surface, and the print clear.

M. P. RAVENEL

Why Men Fail. Edited by Morris Fishbein, M.D. and William A. White, M.D. New York: Century Co., 1928. 344 pp. Price, \$2.00.

Why Men Fail is a book of 344 pages containing 13 chapters on such subjects, as Parents of Failures, The First Job, Sex Has Thrown a Bomb Into Business, Wives Who Help Their Husbands to Fail, "Queer" Failures, Day-Dreamers and Bluffers, Beating Handicaps, Handicap-or Alibi, Fear, Why Women Fail, Job Misfits, and Home-Made Failures.

The title of the book is accurate, but from the sales viewpoint unfortunate. The surreptitious buyer will not want his friends to suspect him of a personal reason for needing it. Many outwardly successful men are inwardly conscious of failure.

As the complexities of life increase so do the chances for failure, because our individual mental machinery cannot carry the additional load required for success. "Of all the beds in all the hospitals throughout the United States," says Dr. William A. White in the introduction, "one in every two is for mental

disease; in other words, there are as many beds for mental ailments as for all other ailments put together." This does not include the large number with minor mental defects who somehow manage, though inefficiently, to carry on.

This book is the result of a conference in Cincinnati, O., on why men fail. It was attended by the leading psychiatrists of the country. Many of us are unaware of malfunctioning relationships, or, if aware, where to begin tightening up the machinery. Also, most of us have rather confused ideas about what a psychiatrist is and does. In a word, he is an unraveler of hidden causes who then helps to reconstruct maladjusted persons. The reading of this book establishes increased confidence in the existence of practicable solutions to problems of failure.

In speaking about melancholia one of the authors, Dr. Karl A. Menninger says: ". . . Few realize that murder is of much less frequent occurrence than suicide. Moreover, the victims of suicide are, generally speaking, far more desirable members of society than the victims of murder."

One does get the impression that most of the roads on which society's misfits travel, if pursued sufficiently far, lead to the psychiatrist's door. But what if they do? It's no disgrace to be mentally sick. And without an understanding guide, this road might have a more unhappy ending.

W. W. PETER

Physiology—By V. H. Mottram, Professor of Physiology in the University of London. New York: W. W. Norton & Co., 1928. 279 pp. Price, \$3.00.

Many years of teaching physiology convinced the author that the average student was overwhelmed by the size of textbooks, and their apparent lack of beaten tracks brought discouragement. He determined on a plan which would give the beginning student a bird's-eye

view of the boundaries and important features as a preliminary to future study. After making a sketch plan of the foundational material, he was induced to add the most recent views of physiologists in simple and untechnical language. The present book, therefore, has been designed as an introduction to the study of physiology, not only for medical students, but for all others requiring a general knowledge of the subject. Indeed, the book is so written that any well educated person can understand it.

The author takes as a sort of text the question "How Does the Human Body Work?" The first chapter gives a survey of the field of physiology, and ends with the statement: "The result of countless years of evolution is an organization which works on common sense principles." Successive chapters are devoted to the various parts of the body and explain their functions. It seems to us that the nervous system is very properly considered first, on the ground that the "... nerves bear the brunt of modern civilization and a healthy nervous system is more important in daily life almost than any other part of the body."

In closing the author modestly says that he has given only the slightest sketch of the realm of physiology, and advises the study of more complete books. While we have no desire to dispute what he says, we must express the opinion that anyone who reads this work understandingly will have a very clear idea of the subject, and only those who are intending to specialize in teaching or research, need go any further.

The book is well printed on light paper with a mat surface. It is well illustrated in black and white. Within the field selected, we know of no book which can be more safely recommended. The author has evidently read widely, and relieves the tedium of difficult study by many interesting references, in addition

to which he has a terse way of impressing facts upon the reader.

M. P. RAVENEL

The Mental Health of the Child—
By Douglas A. Thom, M.D. Cambridge: Harvard University Press, 1928. 46 pp. Price, \$1.00.

In this little book, Dr. Thom has discussed in very simple terms some of the important factors to be considered in developing and preserving the mental health of the child. In these pages he discusses the modern attitude toward mental health, showing the very important part that the early life of the child plays in the later adjustment of the human being. The relation of adults, particularly parents, to the problems which come up in the life of the child are particularly stressed, and two case stories are given to illustrate their relation to the development of some such common problems as temper tantrums, masturbation, and so forth. Throughout this little book, emphasis is continually laid on the fact that behavior is the resultant of many relationships and situations affecting the life of the child, and that the understanding of his behavior means the understanding of motives and of these basic things. He particularly stresses the point that a child must gradually develop his own independence and free himself from the dependency situation which is normal in infancy and which is gradually lessened in the normal course of growth and development.

FREDERICK H. ALLEN

Clinical and Abnormal Psychology
—By J. E. Wallace Wallin, Ph.D.
Boston: Houghton Mifflin, 1927.
xvii, + 649 pp. Price, \$3.00.

The study of the individual, his original endowment, his problems, relation to environment, reactions and ability to adapt are assuming an ever-increasing importance. As a result the clinical psychologist is now with us; his avowed

function is the scientific study of these factors. To correlate and delimit the field and to make the subject accessible to students, educators, social workers and others interested in abnormal behaviour problems, are the objects of this book.

There is a short introduction to the subject and definition of what the author means by clinical psychology. He then proceeds systematically and didactically, in the pro and con method, to deal with its various aspects.

The second part of the book deals with the general level of intelligence, and specific intellectual abilities and disabilities. There is a concise historical and critical survey of the development of the various psychometric procedures, with special reference to the Binet-Simon group. The psychology of the special senses, with illustrative cases, is clearly discussed. Memory, attention, associational processes, normal and pathological, are fully treated from the theoretical and experimental viewpoints.

The author gives a brief outline of some of the psychoses and succeeds in familiarizing the reader with symptomatology. Psychoanalysis receives the usual summary and almost complete rejection, by this author, on at least seven counts.

Neuropsychiatrists, if they read this book, might perhaps disagree with several phases of it. The elusive difference, according to the author, between the clinical psychologist and the psychiatrist, gives to the latter quite different proportions. One does not feel inclined to believe that Dr. Wallin's outline of requirements are quite sufficient to enable one to make clinical diagnoses, even though he does advise "a minimum amount of medical work including physical diagnosis [*sic*], pediatrics, nose, throat, eye and ear disorders, orthopedics, mental deficiency from the physical standpoint and neurology (particularly

the nervous and mental disorders of childhood)." Truly a large order even—"if the student begins to specialize in his senior year at college . . ." Fundamentally the idea embodied in this "mushroom specialist" concept is absurd. One does not acquire medical training by the "course" method. A clinical diagnosis involving the special knowledge of the possible physical factors involved should only be made by a qualified physician.

One or two, perhaps minor details, are noteworthy and illuminating: The footnote on page 316, ". . . upon development of the frontal lobes of the cortex (the layers of gray matter covering the *cerebrum and cerebellum*)" [*Italics reviewer's*]; the sentence on page 443, "When there is an excessive secretion of sugar (*glycosuria*) the excess supply passes into the urine and blood . . ."

Where the author deals with his own subject and within his special field he is clear, concise, critical and worth reading. The bibliography is valuable.

M. RALPH KAUFMAN

Laboratory Manual for the Detection of Poisons and Powerful Drugs—By Dr. Wilhelm Autenrieth, authorized translation by William H. Warren, Ph.D., Philadelphia: Blakiston, 1928. 698 pp. Price, \$6.00.

This is the 6th American edition translated from the 5th German edition, which has been completely revised and provided with extensive additions. Dr. Autenrieth's book is so complete that it almost defies adequate reviewing.

The volume treats of those substances which distill at boiling temperatures from acid aqueous solutions, and considers these in the first group. Those members which are non-volatile under these conditions, such as salicylic acid, caffeine, etc., are considered in the second group. All those metallic poisons constitute a third group. The fourth

group concerns itself with the materials not considered in any one of the three previous groupings. A chapter is devoted to apparatus and special methods of examination, and the closing chapter is devoted to quantitative estimation of certain alkaloids and other principles in crude materials. This edition has a supplement devoted to the preparation of reagents and the detection of blood stains and human blood. And lastly, an appendix in which the narcosis theory of Meyer and Overton is discussed, along with certain other special subjects relating to alkaloids.

A colorimetric method for the estimation of minute quantities of hydrogen sulphide in water and air is described.

This volume should continue to hold its high place in the laboratory devoted to the detection of poisons and drugs in the animal body.

LEONARD GREENBURG

Handbook for the Medical Soldier—

By Major A. D. Tuttle, Medical Corps, U. S. Army, New York: William Wood, 1927, 691 pp. Price, \$5.00.

The need in the new and changed post-war Army for a comprehensive manual for the Medical Departments of the Regular Army, the National Guard, and the Organized Reserves has now been filled. This handbook has been carefully prepared and abounds in information for the medical soldier and for others interested in medical and sanitary problems of the Army. It contains a foreword by Surgeon General Ireland. Basic technical subjects, such as first aid, elementary anatomy and physiology, materia medica and pharmacy, nursing, hygiene and sanitation, mess management, foods, minor surgery, clerical work, and the care and operation of motor vehicles are given in some detail. An enormous amount of valuable material has been assembled in a relatively small space. The book is clearly written, contains 24 chapters, 180

illustrations, and has a flexible binding.

While it is designed primarily for the enlisted man, this manual should prove invaluable for medical officers and nurses, as well as for others interested in national preparedness.

IRA V. HISCOCK

Max von Pettenkofer. *His Theory of the Etiology of Cholera, Typhoid Fever and Other Intestinal Diseases—A Review of His Arguments and Evidence—By Edgar Erskine Hume, M.D., Dr. P.H., LL.D., Major, Medical Corps, U. S. A. New York: Hoeber, 1927. 142 pp. Price, \$1.50.*

Major Hume has performed a real service in making available for the first time a biography of Pettenkofer, the German scientist who was one of the first great epidemiologists. This little book is more than a biography, however, for only about one-third is devoted to the events of Pettenkofer's life. The remainder of the text considers in an interesting manner the work of Pettenkofer on cholera and typhoid, and his deductions and theories concerning the nature of the spread of these and other intestinal diseases. A bibliography of 227 publications by this early sanitarian, together with 57 references to articles about Pettenkofer, completes the book. There is no index.

The modern sanitarian, for all his progress, can derive much of benefit from the example of his predecessors. As Hume points out, Pettenkofer was often wrong, according to present knowledge, but he was a versatile scientist who made great contributions to chemistry, physiology, and public health. The life of any man who could clean up a city as Pettenkofer did Munich, and reduce its typhoid death rate to a comparatively negligible quantity, is worth knowing about. The sanitarian can, therefore, read Major Hume's book with profit.

JAMES A. TONEY

The Essen Number—*Report of the convention of the Association for Water, Earth and Air Hygiene held in Essen in June, 1927. Published by and obtainable through the Landesanstalt für Wasser-Boden-und Lufthygiene, Berlin-Dahlem, Eherenbergstr. 38-42. 1927. 518 pp., 288 ill. Price, 12 R. M.*

This volume contains the proceedings of the twenty-fifth annual convention of the Association for Water, Earth and Air Hygiene held in Essen in June, 1927 (first convention outside the city of Berlin). The location of Essen in the Ruhr Valley in the heart of a thickly populated industrial section offered exceptional attractions for such a convention.

At the same time as the convention there was an exposition ("Achema") of chemical apparatus held in Essen under the auspices of the Division for Water Chemistry of the Association of German Chemists (Vereins Deutscher Chemiker). Part 9, pages 439-494, of the volume is given over to a description, profusely illustrated, of the apparatus exhibited at this exposition.

The papers covered the entire field of sanitary science from the engineering phases of water supply and waste treatment, the effects of air pollution on human population and vegetation, to the disinfection of clothing and the control of vermin. The following is a list of the papers presented at this convention:

Water and Sewage in the Rhine-Westfall Industrial Area, especially, with Reference to the Emscher- and Lippe Association, by H. Helbig

Sewage Treatment Works of the Emsch Association, by M. Prüss.

The Disposal of Settled Sludge from a Chemical Standpoint, by H. Bach

The Work of Ruhrverband, by Dr. K. Imhoff.

River Clarification and Power Installation at Hengstey, by O. Spetzler

Biological and Chemical Sewage Purification with the Aid of Air, by Dr. F. Sierp

The Left Lower Rhine Drainage Board in Moers Niederrhein, by K. Fehring

The Ruhr Valley Reservoirs, the Möhne and Sorpe Reservoirs, by E. Link

The Water Supply of the Ruhr Coal District from the Hygienic Standpoint, by H. Bruns

The Water Supply of the City of Essen, by B. Nerreter

Permutit Water Purification with a Special Reference to the Circulatory Regeneration System of Hufschmidt, by K. Hofer

Air Hygiene, by E. Wernicke

Vegetation and Poisonous Gas, especially Sulfur Dioxide, by E. Tiegs

Chemical Questions of Air Hygiene, by W. Liesegang

Air and Dust Investigation of the Rhine-Westfall Industrial Area, by H. Reiserer

Air Pollution and Prevention, by L. Diesfeld

Question of Health Hazard of Factory Air, by F. Müller-Voigt

Communal Hygiene Questions in the Field of Vermin Control, by J. Wilhelmi

Description of Apparatus Exhibited at the Chemical Exposition ("Achema"), by H. Bach

The subjects are all clearly and authoritatively treated, and profusely illustrated. The volume furnishes an exceedingly valuable summary of current practice in the field of sanitation. The questions are naturally discussed from the standpoint of applications to German conditions but references are frequently made to recent progress in other countries. Of the 350 delegates to this convention a considerable number came from foreign countries.

A. W. BUSHWELL

The Present Status of Preschool Hygiene in the United States—

By Frances M. Hollingshead, M.D., Director, Buffalo Foundation, Buffalo, N. Y. 40 pp.

This monograph is one of the most comprehensive résumés prepared recently on preschool hygiene and represents careful research work. The monograph was originally presented as a paper before the Child Hygiene Section of the American Public Health Association at the 56th Annual Meeting at Cincinnati, O., October, 1927. This monograph of 40 pages has been put out in attractive form. Copies of it are available from the Buffalo Foundation, 714 Marine Trust Bldg., Buffalo, N. Y. A. B. T.

That Mind of Yours. A Psychological Analysis—By Daniel B. Leary, Ph.D. Philadelphia: Lippincott, 1927. 266 pp. Price \$1.75.

This book is the outcome of a series of articles which have been running in the *Buffalo Evening News* for four years. The author describes it as "the story of modern psychology," and he professes to explain what psychology is, its problems and their solutions, as the modern psychologist sees them. He holds that there are real standards, but in the past we have gone from sandhill to sandhill, and only now have we discovered real solid foundations on which to build. This shows the optimistic vein in which the book is written.

Further on he acknowledges that there are many definitions of psychology, a number of which he gives and discusses. His first and simplest definition is that it is "a point of view," "a way of looking at human beings and their conduct." To those who have followed the reviews of a number of books on the subject during the past year, this is illuminating. The fact of the matter seems to be that psychologists themselves are not agreed on a definition, and have divergent views as to fundamentals. There are almost as many definitions as there are books on the subject.

The author is not a physician. He acknowledges, however, that many physicians have made notable contributions to the science, though they have not been students of psychology. On the other hand, he confesses to an opinion, which we believe the average physician arrived at many years ago, "that many so-called psychologists, particularly those of the inspirational school and the optimistic uplift Pollyanna persuasion, know little or nothing of biology and medicine."

The reviewer makes no pretense at being a psychologist in spite of the fact that an earnest effort has been made to understand what that profession is driv-

ing at. Some members have made real advances.

It must be remembered that this book is written for the laity, and we believe it to be better than the average of its class.

M. P. RAVENEL

Fundamentals of Dairy Science—

By Associates of Lore A. Rogers in the Research Laboratories of the Bureau of Dairy Industry, U. S. Department of Agriculture. New York: Chemical Catalog Company, 1928. 543 pp. Price, \$5.50.

The accumulated wisdom of the ages with respect to the biology, chemistry, bacteriology, and general scientific aspects of milk and milk products has been assembled in this notable volume, to which numerous experts have contributed. Nearly everything now known and understood about this most important of the foods of man seems to be presented here in a thorough, accurate, and at times extremely technical manner. It is stated in the preface that the book is designed for advanced students and research workers in the field of dairy science. As a consequence, parts of it are far from popular in style, but all of it will be indispensable as a reference text to any scientist or sanitarian who is concerned in any manner with milk.

The four parts of this book take up: (1) the constituents of milk; (2) the physical chemistry of milk and milk products; (3) the microbiology of milk and its products; and (4) the nutritional value of milk, and also the physiology of milk secretion. Numerous references are given at the end of each chapter, and there is an excellent index. The book is exceptionally well printed and arranged, for which the publishers and the editorial committee of the monograph series of the American Chemical Society deserve credit. The book can be recommended highly as well worthy of the great scientist and teacher to whom it is dedicated.

JAMES A. TOBEY

Laboratory Manual for General Biology and Fundamental Embryology

—By John Giesen. (2d. ed.) Milwaukee: Bruce Pub. Co., 1927. 215 pp., 11 figs. Price, \$1.80.

This is a laboratory guide for a typical elementary course in elementary zoölogy and botany, and the embryology of the frog and chick. It is in the form of a terse didactic outline of directions, with some supplemental data on the sources and care of laboratory material and the making of microscopical preparations. The author has not brought his nomenclature up to date, but still uses *Distomum* for *Fasciola* and *Trichina* for *Trichinella*. C. A. KOFOID

Anthelmintics and Their Uses in Medical and Veterinary Practice

—By R. N. Chopra and Asa C. Chandler. Baltimore: Williams & Wilkins., 1928. 291 pp. Price, \$5.00.

The present work is an extremely thorough and painstaking review of the subject of anthelmintics and reflects the wisdom of combining the viewpoint of a pharmacologist with that of a helminthologist. It is divided into three sections. Section I deals with general considerations such as methods of administration and investigation and with the correlation between chemical composition and anthelmintic action of drugs. In surveying the therapeutic agents that have been discovered the authors point out that among the intestinal worms, hookworms and their allies, ascarides, stomach worms and flukes are fairly susceptible; tapeworms moderately so; but oxyurids, *Strongyloides*, *Trichostrophus* and *Trichuris* are in the main non-susceptible. Only recently has progress been made with the somatic forms. Fair treatments have been devised for liver flukes, schistosomes and lung worms, but no effective treatment has been found for the filariae. This section

also includes a general survey of the worms infecting man and domestic animals to which is appended a key for eggs, larval forms and adults of the common worms.

In section II which deals with the drugs acting on gut parasites, two chapters are devoted to drugs acting on cestodes, the best known of which are male fern and allied drugs; ten chapters are devoted to drugs acting on nematodes and in the long list of agents especial attention is paid to such important remedies as carbon tetrachloride, oil of chenopodium, santonin and thymol. Chapter XV lists a number of proprietary anthelmintics, but the authors remark that although some of these have given fairly good results, they prefer to use ordinary drugs whose pharmacological and toxic actions are better known.

Section III consisting of three chapters is devoted to anthelmintics used against somatic worm infections. Particular attention is given to the antimony compounds and emetine and their use in schistosomiasis. The authors believe that emetine is not so efficacious as the antimony tartrates in the treatment of schistosomiasis and is, furthermore, much more expensive.

Throughout, each of the more important drugs is considered from the standpoint of history, source, chemical composition, pharmacological action and toxicity, dosage and anthelmintic effect. An exceedingly important feature of the book is an extensive bibliography covering 22 pages. The index is very well arranged in that the practical worker can find a list of the various drugs under each genus of worms. The present volume will be almost indispensable for either medical or veterinary workers interested in the treatment of worm infections, and should find a place in all laboratories dealing with any phase of experimental helminthology.

W. H. TALIAFERRO

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Portsmouth, Va.—Published as a part of the report of the city manager, the 1926 record of the Department of Public Welfare is creditable. A general death rate of 11.5 is somewhat higher than that for 1925 (10.7), due in part to a slight increase in deaths from pneumonia and cerebral hemorrhage. Six diseases caused over half of the 691 deaths, as follows: tuberculosis 38, cancer 23, cerebral hemorrhage 95, pneumonia 88, diseases of the heart 59, and chronic nephritis 57. It is noteworthy that only 1 death from typhoid was recorded. There were 1,029 births; and 100 infant deaths, of which 28 occurred during the first day, and 55 during the first month of life.

The laboratory division report shows a good range of examinations, with a total of 5,135, classified according to type. Commendable progress in this division is noted in comparison with the previous year.

Under the nursing division, it is noted that home nursing classes have been carried on, a central clinic, chiefly preventive, has been opened, and a health station, started in a colored section, has been active.

Newport, R. I.—The 1927 report of the Newport Board of Health is well arranged and informative. New and more spacious offices in the City Hall, with new equipment for laboratories and a dental clinic are noted. This city of 30,044 population, reports 447 births and 316 deaths, and an infant mortality rate of 40 deaths of infants per 1,000 births. A classified financial statement indicates an expenditure by the health department of \$25,778 for collection and disposal of wastes, and \$20,067 for purely health purposes.

There were 5 cases of diphtheria with

no deaths. A total of 2,689 children were given toxin-antitoxin, and 1,528 were given subsequent Schick tests, while 1,631 children who had not been previously immunized were given the Schick test. Active milk supervision has been exercised. The report concludes with many statistical tables worthy of study.

Hartford, Conn.—The 43rd report of the Hartford Board of Health for 1927 has a good light yellow cover, and on the second page contains an excellent statistical summary for the years 1926 and 1927. This city of 168,258 population had a resident death rate of 9.44, a resident birth rate of 20.2 and an infant mortality rate of 68.5. The death rate from pulmonary tuberculosis was 61.8. A decrease in deaths from lobar and broncho-pneumonia is recorded. Several good charts, most of them covering periods from 1881, and numerous statistical tables add interest to the report of progress.

Another year of successful coöperative work for infants and preschool children with the Visiting Nurse Association is noted by the health officer. Under the terms of the agreement, the city employs the V. N. A. as its agent to do the routine work at the health stations, and bills for their services at cost are rendered by them each month to the Board of Health. A total of 6,303 cases were registered, with 19,000 visits to the stations, in addition to the nursing visits to homes. A classified financial statement, with comparative figures for 1926 and 1927, shows a per capita expenditure in the latter year of \$1.40.

Greenville, S. C.—Greenville's annual report for 1927 is published in the monthly bulletin and is a record of prog-

ress for this city of 33,000 people. The number of diphtheria cases reported was half the number of the previous year, with no cases reported among colored children. During the past $2\frac{1}{2}$ years, all of the colored school children have been immunized. A resident death rate of 10.5, with no deaths from diphtheria, scarlet fever, or typhoid fever, and an infant mortality rate of 73.5 are recorded. The standard milk ordinance was adopted in 1926, and a new ordinance is now before the council governing the manufacture and sale of ice cream. All slaughtering is done in a modern abattoir where ante-mortem and post-mortem inspections are made. An annual appropriation of \$1,500 per year is made for mosquito control work.

Los Angeles County, Calif.—The annual report of the board of supervisors of Los Angeles County, Calif., (year ending June 30, 1927) contains 318 pages with many financial and statistical tables, several attractive photographs, and a small amount of descriptive text. An effort is being made to protect unincorporated areas through proper zoning and the establishment of definite building lines in districts where deed restrictions have expired. It is stated as the policy of the Regional Planning Commission to obtain from, or have reserved in the larger subdivisions, suitable park, school playground, beach or other open spaces of recreational or public nature in order to maintain a balanced community.

In the health department report section it is learned that during the early part of the year, a severe epidemic of smallpox was quickly stamped out and 160,000 people were vaccinated free, "representing a saving to the people of at least \$200,000." During the year vaccines and serums for prevention of disease were distributed at a cost of approximately \$15,000. The population is said to have increased $2\frac{1}{2}$ times dur-

ing the past 3 years, but communicable diseases have not increased to a similar extent. Laboratory services were increased 100 per cent in a year, for bacteriological work, and 30 per cent for chemical analyses.

Preventive work in tuberculosis control is carried out through the summer schools in coöperation with the county tuberculosis association. The infant mortality rate of 41 per 1,000 births is a record for a large rural district. There were 25,576 mothers who received free service on the education of the child at the health centers during the year. Co-operation has been established with 135 school districts in the joint employment of public health nurses. Twenty-five cities have coöordinated their work with the county health department.

American Child Health Association.—The *Fourth Annual Meeting Transactions* (May, 1927) of the American Child Health Association are published in a volume of 380 pages. This is a valuable compilation of addresses dealing with the various problems of modern child hygiene work. Here may be found enlightening discussions of progress in child health as viewed by national organizations; the promotion of child health through recreation; trends in federal and state child health work; and experience in medical schools with courses in preventive pediatrics. Many interesting graphs, statistical tables, and charts are reproduced to show the present status of different aspects of health work as compared with earlier years.

The coöperative program of the association is effectively outlined by the general executive. "What we covet, therefore, is the opportunity of securing productive coöperative service, when desirable and expedient, with the official agencies upon which government has placed the responsibility of advancing the cause of child health. It has also been our pleasure to join with other

voluntary health agencies and with the great national social and civic groups in the fields of our common interest and endeavor.

As an illustration of the type of co-operative work undertaken, the nationwide campaign for clean and safe milk is described. After a working plan for a state survey has the joint approval of the state department of health, the state dairy commissioner and the representative of the association, the work starts in the survey phase. An effort is made to secure a picture of the actual sanitary and chemical quality of the marketed milk in a cross-section of the state, together with definite first hand knowledge of the problems associated with milk production and distribution. Experts then point out the defects in routine methods and equipment, and offer suggestions for betterment. Finally

comes the phase of interpretation and promotion when, through carefully planned follow-up of the survey, the results are interpreted to the various civic and social groups and the importance of milk in the dietary of the growing child is stressed.

Educational workers proceed similarly with respect to the schools. They sample and analyze educational thought and practice relating to school health programs; and interpret, demonstrate, and promote activities along modern lines of accepted practice. At present, the association is engaged in a study of the effectiveness of the health program in the schools of the country which should yield valuable information that may be used to measure, in terms of health status, habits and knowledge of pupils, and the effectiveness of existing school health activities.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Diphtheria Mortality in 1927—The Atlantic Seaboard States had, during 1927, a diphtheria mortality higher than the previous year. The Central States have a much greater increase, whereas the Pacific States showed a decline.

ANON. Diphtheria Mortality in Large Cities of the United States in 1927. *J.A.M.A.*, 90:20 (May 19), 1928.

Typhoid Fever in 1927—Seven of the cities of more than 100,000 population had no typhoid fever deaths. Seventy-four had less than 2 per 100,000. There has been a progressive decline in each group for the past 3 years.

ANON. Typhoid in the Large Cities of the United States in 1927. *J.A.M.A.*, 90:20 (May 19), 1928.

Toxins of Hemolytic Streptococci—Polyvalent toxins from scarlatinal erysipelas and suppurative streptococci produced similar skin reactions and were neutralized by antitoxin prepared from any of the three toxins. The scarlatinal antitoxic serum was the most comprehensive in its neutralizing powers.

ANDO, K., et al. Relationship of the Toxins of Different Hemolytic Streptococci as Brought Out by Tests on the Human Subject. *J. Immunol.*, 15:3 (May), 1928.

Liver in Anemia—The active principle in liver effective in anemia is water soluble and free from iron, protein, carbohydrate, and lipid. It is probably either a nitrogenous base or a polypeptide.

COHN, E. J., et al. The Nature of the Material in Liver Effective in Pernicious Anemia. *J. Biol. Chem.*, 77:2 (May), 1928.

Diphtheria Among Contacts—Diphtheria is more prevalent among the family contacts of "carriers" within the first month than in a comparable popu-

lation living in the same neighborhoods. Persons harboring bacilli classified as avirulent may be of importance in the spread of the disease.

DOULL, J. A., et al. The Incidence of Clinical Diphtheria Among Family Contacts Subsequent to the Discovery of Carriers. *J. Prev. Med.*, 2:3 (May), 1928.

Skin Sensitivity to Scarlatinal Toxin—Four papers reporting studies of skin sensitivity in infants with and without streptococcal infections and treated with various sera.

COOKE, J. V. Scarlet Fever. *Am.J.Dis.Child.*, 35:5 (May), 1928.

Terminal Disinfection—Shall terminal disinfection be discontinued? Not entirely, is this British reviewer's opinion. Concurrent disinfection fills the bill with most diseases, but for smallpox he has his doubts. Disinfecting methods are discussed.

FARR, E. C. Present Tendencies Regarding Disinfection. *J.Roy.San.Inst.*, 47:11 (May), 1928.

Measles in Institutions—Rigid isolation of institutions caring for children under 3 years is justified when measles is epidemic. Management of contacts and the hygiene and care of the sick are the most important factors in prevention. Convalescent serum is a valuable adjuvant. These are some of the conclusions of this valuable paper.

GODFREY, E. S. Measles in Institutions for Children. *J.Prev.Med.*, 2:3 (May), 1928.

Scarlatinal Antitoxic Serums—Convalescent serums and antitoxic horse serums were found equally effectual in reducing fever, duration of skin lesions, complications and fatality rate. There was an absence of serum reactions when convalescent serum was used.

GORDON, J. E., et al. Convalescent and Antitoxic Serums in Scarlet Fever. J.A.M.A., 90:20 (May 19), 1928.

Gas Producers in Potable Water—*Cl. welchii*, *B. aerosporus*, *streptococcus fecalis* and undetermined organisms were found in Lake Michigan water and render the 48-hour presumptive test for *B. coli* valueless during part of the year.

GREIF, F. E. The Sanitary Significance of Lactose Fermenting Bacteria Not Belonging to the *B. Coli* Group. J.Infect.Dis., 42:5 (May), 1928.

Thermophiles in Pasteurized Milk—Pasteurizers should be flushed with hot water just before use to prevent seeding of milk with thermophilic bacteria. Rapid cooling prevents increase in counts.

HARDING, H. A., and WARD, A. R. High Bacterial Counts in Pasteurized Milk. Pub. Health J., (Canadian), 19:4 (Apr.), 1928.

Chlorination of Water—A useful review of the development of water chlorination procedures including pre-chlorination, superchlorination, and the use of chloramine.

NEWS FROM THE FIELD

LIVESTOCK LAWS

A close check-up on the laws governing the interstate movement of livestock and veterinary biological products, which has been made recently by the Bureau of Animal Industry, U. S. Department of Agriculture, has resulted in fines and jail sentences for the offenders. In the case of livestock quarantine laws, 4 violators were fined from \$100 to \$250 for driving or shipping cattle interstate without previous tuberculin test. Another violator was jailed. Five railroads were also penalized from \$100 to \$400 each for violating the 28-hour law, providing for the unloading of live stock for feed, for water and rest.

The license of one firm producing biological products has been revoked and another license has been suspended. Investigation showed conditions in the laboratories to be defective, insanitary and improperly conducted and the products contaminated.

COURSE FOR CONTINUATION SCHOOL WORKERS

A course in health education for workers in continuation schools will be inaugurated at Teachers College, Columbia University, with the opening of the college term in September, 1928. This is the first course of the kind ever to be offered in any university. The course is planned to meet the specific needs of continuation schools as they have been determined by a study made recently of the New York City Continuation Schools. The course will include Safety & First Aid in the Job; Posture and the Job; Nutrition for the Worker.

The course has been approved by the New York Board of Examiners and will be accepted for credit toward a teaching license for continuation schools. Thomas

A. Wood, M.D., professor of health education, Teachers College, will direct the course and will give some of the lectures. The lecturers also will include Hugh Grant Rowell, M.D., assistant professor of health education, and Anette M. Phelan, instructor in health education, Teachers College, John D. McCarthy, M.D., director health education for New York City Schools and others prominent in this field.

ROCKEFELLER HEALTH PROJECTS

MORE than \$11,000,000 was expended in 1927 by the Rockefeller Institute according to the report of George E. Vincent, M.D., president. Among the public health projects in the United States promoted by the Rockefeller Institute in 1927 were:

Aided local health organizations in 85 counties in 6 states in the Mississippi flood area.

Operated an emergency field training station for health workers in flood area and 9 other training stations elsewhere.

Assisted 9 schools or institutes of public health and 3 departments of hygiene in university medical schools.

Had a part in malaria control demonstrations or surveys in 8 southern states.

Contributed to the health budgets of 265 counties in 23 states.

Helped to set up or maintain public health laboratory services, or divisions of vital statistics, sanitary engineering or epidemiology in state health departments in 16 states.

Made grants for mental hygiene work.

Provided funds for biological research at 3 American universities.

T-A FOR PRESCHOOL CHILDREN

THAT health education properly directed coupled with effective organization will bring results is shown by the record of Batavia, N. Y., in its toxin-antitoxin campaign. During February and March, 910 children received three doses of toxin-antitoxin and of this number 312 were of preschool age. School

authorities, both public and parochial, the Parent-Teacher Association group, and the local newspapers coöperated in the campaign. The local board of health appropriated \$500 to pay the physicians who volunteered their services at the clinics.

POUGHKEEPSIE CITY FATHERS PROMOTE T-A DRIVE

THE Board of Aldermen of Poughkeepsie, N. Y., made an appropriation, by unanimous vote, of \$2,000 to meet the expenses of a toxin-antitoxin campaign carried on in May. An arrangement was made to pay physicians in charge of the clinics \$50 per clinic.

LYNN HABIT CLINIC

A new habit clinic has been established in Lynn, Mass. The clinic will be in charge of Dr. C. A. Bonner, superintendent of the Danvers State Hospital, Lynn, Mass., who is an expert in the field of mental hygiene of children. The clinic staff also includes Mary H. Holland, social worker, and Esther Reid, psychometrist.

PROTEST AGAINST DR. LEVY'S DISMISSAL

AROUSED by the removal of Dr. E. C. Levy as health officer of Tampa, Florida, for political reasons only, the Hillsboro County Medical Society, Florida, has gone on record protesting against his removal.

Commending Dr. Levy for his harmonious coöperation with organized medicine and referring to the complete confidence of the medical profession which he enjoyed, the local medical society, through its committee on resolutions, with J. C. Mills as chairman, went on record claiming:

That in being deprived of the services of a man whose work here in Tampa has fully borne out his previous reputation as the best municipal health officer in the United States, Tampa has lost not only a most efficient guardian of the health of its people, but also that prestige and distinction that comes from having such a man at the head of its Health Department.

TEXAS TO BUILD CHEMICAL LABORATORY

THE Texas State Board of Health recently made provision for the erection of a \$25,000 state chemical laboratory to be directed by Dr. S. W. Bohlo. Dr. Bohlo will continue to direct the Pasteur Institute which is to be combined with the state laboratory. Maudie Marie Burns will be pathologist of the new laboratory.

The laboratory will be built on a state-owned square in the City of Austin and ready for occupancy September 1.

ECUADOR NEW PUBLIC HEALTH LAW

THE public health law of Ecuador of June 17, 1927, provides punishments of from 1 to 5 days in prison and fines of from 1 to 100 sucres, or both, for parents or guardians guilty of the following:

Placing child with nurse not having a certificate of health from a physician

Failure to have a child vaccinated against smallpox within a certain period of time

Leaving child locked in the house and going away to work

Failure to provide medical care promptly in case of a child's illness, when such neglect results in the death of the child

Punishments as stated above are also provided for mothers who decline to feed their children at the breast without having a physician's certificate stating their inability to do so.

RECENT DEVELOPMENTS IN CHILD WELFARE WORK IN MEXICO

STUDY of physical development of school children—The Department of Public Education of Mexico has just completed a report of an investigation of the physical development of school children between the ages of 4 and 17 in the Federal District. This investigation, which lasted 3 years, included mental as well as physical measurements.

Physical examination of school children—Physical examination of school children in Mexico City, which has been in practice more than 3 years, has been made more extensive this year. All children in the primary schools will be exam-

ined once a year and those needing medical attention will be sent to clinics and dispensaries for free treatment. All children in the secondary, technical, and preparatory schools will also be examined; they will not be sent to dispensaries, but will be given advice necessary for the treatment of the disorders found and the prevention of disease. The Bureau of Hygiene of the Department of Education is also concentrating its efforts on inculcating good health habits among the school children.

New measures with regard to kindergartens—A new division, that of general inspection of kindergartens, was established under the department of education. The staff of this division is in charge of a woman teacher, and consists of several women inspectors of kindergartens. Provision has been made by the new division for the establishment in Mexico City of 18 additional kindergartens as annexes to public schools. For this purpose the poorest districts have been selected.

PRENUPTIAL CONSULTATION CENTERS IN ITALY

A prenuptial consultation center was recently established in Genoa. Two others had been established previously, one in Milan and one in Turin. At these centers persons intending to get married are examined by physicians, and those already married are given hygienic and medico-legal advice.

ITALIAN NATIONAL BUREAU FOR MATERNITY AND CHILD WELFARE

ACCORDING to official information, the National Bureau for Maternity and Child Welfare of Italy, established in 1925, gave subsidies in 1927 of 5½ million lire to 428 maternity and infant welfare agencies, and of 6½ million lire to 606 summer camps in which 180,000 children were cared for. Other activities of the bureau included inspection of 509 institutions for children; giving 50

courses in child care for physicians, midwives, and trained welfare workers; establishment of 9 traveling courses in child care; and operation of 55 traveling child health centers and 53 pediatric and obstetric clinics.

FIRST CUBAN NATIONAL CHILD-WELFARE CONGRESS

A committee under the chairmanship of the Secretary of Health has been working on plans for the First National Child Welfare Congress in Cuba and has decided to hold the congress in December of this year. The congress will continue the work of the Fifth Pan American Child Congress, which was held in December, 1927. Its main objects will be:

1. To bring to the attention of the nation the necessity of giving good care to children
2. To familiarize the public with the progress made in the study of the child
3. To promote the study of hygiene, pediatrics, child psychology, and education
4. To work for the enactment of child-welfare legislation

The Congress will be divided into the following five sections: Hygiene, medicine, psychology and education, sociology and legislation, and defective and delinquent children.

CUBA'S TUBERCULOSIS CAMPAIGN

AS a part of Cuba's anti-tuberculosis campaign, plans for which were prepared by the Department of Health, the government has appropriated 3,000,000 pesos for the construction of several sanatoriums for tuberculous persons. Plans have been made also for the introduction of compulsory reporting of cases of tuberculosis by physicians; extension of the visiting nurse system; keeping of complete statistics of cases of tuberculosis; and education of the public through literature, lectures, motion pictures, etc.

Preventorium for children in delicate health who are not tuberculous will also be established.

PERSONALS

- DR. J. W. H. SMITH, formerly with the New Highland Sanitarium and Clinic, Martinsville, Ind., has become associated with the Ohio Valley General Hospital, Peterson Laboratory, Wheeling, W. Va.
- DR. R. A. STEPHEN has been appointed City Health Officer of El Cerrito, Calif., to take the place of Dr. W. W. Fraser.
- DR. JOHN D. KEYE is now City Health Officer of Holtville, Calif., having succeeded Dr. W. F. Mosher.
- DR. BENJAMIN H. VIAU has been appointed City Health Officer of Sanger, Calif.
- DR. HENRY L. K. SHAW, the first director of the New York State Division of Child Hygiene upon its creation in 1914, and since August, 1919, a department consultant in child hygiene, was elected president of the American Pediatric Society at the annual meeting held at Washington during the week of May 7.
- DR. W. A. DAVIS has been named secretary of the Texas State Board of Health.
- ERNEST LEMAY of Austin, Tex., is the new director of the food and drugs section of the Texas State Board of Health.
- DR. GEORGE H. WILLCUTT has been appointed City Health Officer of Ross, Marin County, Calif. to succeed Mr. M. H. Edgar.
- SURGEON R. M. GRIMM has been relieved from duty at the American Consulate at Antwerp, Belgium, and has been assigned to duty in the American Consulate in Dublin, Irish Free State.
- SURGEON C. H. WARING has been relieved from duty at the Hygienic Laboratory, Washington, D. C., and has been assigned to duty in the American Consulate in Antwerp, Belgium.
- A. L. DOPMEYER, Associate Sanitary Engineer, has been relieved from duty in Interstate Sanitary District No. 4, Memphis, Tenn. on June 15, and has been assigned to duty in Interstate Sanitary District No. 5-6, in San Francisco, Calif.
- DR. PERRY F. PRATHER, Hagerstown, Md., has been reappointed Health Officer of Washington County, Md.
- EDMUND V. COWDRY, Ph.D., of the Rockefeller Institute for Medical Research, New York, N. Y., has been appointed Professor of Cytology in Washington University Medical School, St. Louis, Mo.
- DR. GEORGE M. JENNINGS, Missoula, Mont., was elected president of the State Board of Health on April 5.
- SIR ARTHUR NEWSHOLME, formerly Principal Medical Officer of England and Wales, visited New York City, to make a study of the Health Department's reorganization plan.
- DR. GOLDSBOROUGH F. MCGINNES has been appointed Director of Laboratories of the Virginia State Department of Health to succeed Aubrey H. Straus, who has tendered his resignation, effective June 15. Dr. McGinnes was formerly Health Officer of Isle of Wight County, Va.
- DR. WILLIAM F. WILD, formerly with the American Child Health Association and with the American Society for the Control of Cancer and the Minnesota Public Health Association, has been appointed Health Officer of Bridgeport, Conn.
- DR. JAMES W. BENHAM has been appointed Health Officer of Columbus, Ind. to succeed Dr. John R. Miller.
- DR. RODNEY M. AREY has been appointed City Health Officer of Muscatine, Ia., to succeed Dr. Arthur L. Bryan.
- CHARLES-EDWARD A. WINSLOW, Dr. P. H., Professor of Public Health at Yale University, has been appointed Cutter Lecturer on Preventive Medicine at Harvard University for 1928-29.

DR. THOMAS R. BROWN, Baltimore, Md., has been reelected president of the Johns Hopkins Medical Alumni Association.

DR. FRANK A. HOHENSCHUH has been appointed City Health Officer of Clifton, Ia.

DR. ERESTUS T. HANLEY has been reappointed City Health Officer of Seattle, Wash.

DR. JOHN A. WESSINGER has been reappointed Health Officer of the City of Ann Arbor, Mich. for a term of three years. Dr. Wessinger has served the city continuously for twenty-two years.

ANNE HASBROUCK, formerly with the Brooklyn Health Council, became superintendent of the Reconstruction Home at Elmira, N. Y. on June 1. This institution is supported by the State District Rotary Club.

DR. H. B. EHLE has succeeded Dr. G. S. Martin as Health Officer for Lassen County, Calif.

DR. W. H. ZIEBER has been appointed City Health Officer for Menlo Park, San Mateo County, Calif.

HENRY P. TALBOT, M.D. has been appointed chief of the division of venereal disease, Connecticut State Department of Health. He assumes his duties July 1. Dr. Talbot was formerly with the Public Health Service, Marine Hospital at Ellis Island.

DR. A. J. BURCH has been appointed part-time Health Officer of Catron County, N. M. He is successor to Dr. A. A. McDaniel who has moved from the county.

Supervising Venereal Disease Carriers*

RAYMOND S. PATTERSON, Ph.D., FELLOW A. P. H. A.

*Chief, Bureau of Venereal Disease Control, New Jersey State
Department of Health, Trenton, N. J.*

THE study of known cases of the common communicable diseases to detect sources of infection and contacts is a generally accepted function of health departments. Though detecting diphtheria carriers has been accepted for some years as a reasonable procedure, a systematic tuberculosis case-finding campaign has not generally been made a part of official local health programs. To contract diphtheria was a misfortune; to suffer from tuberculosis was somewhat of a disgrace. Hence we took aggressive measures against diphtheria, but confined our early antituberculosis programs to the building of hospitals and sanatoria for the unfortunate victims of the disease. Not until the Framingham demonstration had shown the way, were case finding programs generally advocated for health departments. If the popular attitude toward tuberculosis delayed the adoption of case finding measures, it is easy to imagine the effect of the stigma of gonorrhea and syphilis upon venereal disease control.

Prior to the war, few hospitals maintained venereal disease clinics in their outpatient departments; little was known of the prevalence of the infections; and nothing was done to find infectious persons and to induce them to accept the limited treatment facilities available. The war emergency revealed the true status of venereal diseases, and a herculean attempt was made to combat them. The war measures consisted principally in a nation-wide extension of the meager medical facilities, an aggressive educational campaign, and the repression of commercialized prostitution.

Clinic facilities for free diagnosis and treatment are essential; for otherwise indigent patients, suspected carriers who are required to

* Read at the New England Public Health Institute, Providence, R. I., Sept. 30, 1927.

submit to examinations, and infectious cases under compulsory treatment cannot be cared for. But medical treatment facilities alone without social service are an ameliorative rather than a preventive measure. All are agreed that sex education is an important factor in preventing venereal infections, and hence should not be neglected; yet none is so sanguine as to believe that information about the dangers of venereal infection alone will deter all persons from exposing themselves to these diseases. Again, vice repressive measures are equally indispensable, for they make commercialized prostitution difficult and thus tend to close the most fertile avenue for the spread of the diseases. Yet police repression of public prostitution cannot prevent the much more numerous clandestine prostitutes from spreading infection. These three measures have been carried on in New Jersey since the war as in other states, but important as they are they lose their effectiveness unless they supplement a determined effort to find through epidemiologic methods the relatively few infected persons who are sexually promiscuous. In New Jersey this additional step has been taken, i.e., the detection and supervised treatment of the persons responsible for the spread of the venereal diseases.

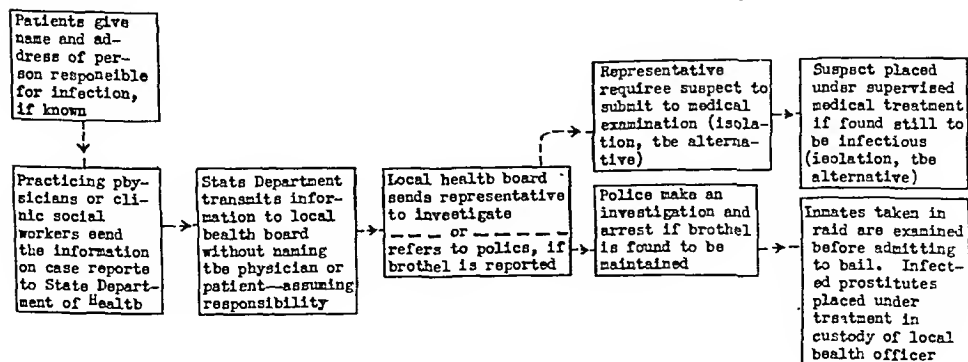

For the past five years the New Jersey State Department of Health has urged practicing physicians and clinic social workers to obtain information about the source of infection from all patients recently infected with a venereal disease, and to include the name and address of the source in their case reports. The response to the request was slow at first, but the continued improvement has been encouraging, for the number of physicians who give this assistance has increased to the point where for the past two years about one-tenth of all the case reports (chronic and acute alike) have included in them the name and address of the probable source of infection. The percentage of active cases giving the desired information about the source is much greater than one-tenth, for in the clinics in the larger cities the social worker who takes the patient's history obtains the information about the source of infection. As she is the deputy of the local health officer, the social worker investigates the reputed source immediately, and therefore does not include sources of infection on the case reports which she sends to the State Department of Health because the information is unnecessary.

In New Jersey, physicians report venereal disease cases direct to the State Department of Health instead of to the local registrar. When reports in which a source of infection is named are received from practicing physicians, the State Department of Health, without divulging the name of the physician or his patient, sends to the local health board

having jurisdiction the name and address of the suspected person. If a house of prostitution is named as the place in which the infection was contracted, this information is referred through the health officer to the police officials having jurisdiction, with the request that an investigation be made and the appropriate action be taken to close the house. More than a hundred brothels or professional prostitutes were reported in this manner during the past year and have been investigated by police officials.

If a man or woman is named as the source of infection, the venereal disease social worker or, if none is employed, a nurse or an inspector delegated for this work by the health officer investigates the report. If the investigator is successful in locating the person suspected of being a focus of infection, guarded inquiries are made about the suspect, and, unless the person's reputation is above reproach, he (or she) is informed that the State Department of Health has reported him (or her) as suspected of being infected with a communicable disease and that the law requires the health officer to demand a physical examination either by the family physician or at the public clinic. The suspected person is assured that no publicity has been or will be given to the investigation and that no one will be informed of the nature of the suspected condition as long as treatment is continued.

In only a very few cases, among the many hundreds of such investigations made during the past five years in New Jersey, have persons been named whose reputation was such as to make it inadvisable to ask the person to submit to examination. When this has occurred, the investigation has been dropped on the assumption that such a person would be unlikely to expose many persons to infection and that it would be better not to require a person possibly innocent of illicit sex relations to submit to examination. It should be noted that when suspected persons are approached they assume, usually, an attitude of injured

STEPS IN FINDING FOCI OF VENEREAL INFECTION

innocence, but the fact that they have been reported by the State Department of Health to the local health departments and that the health officer is "after them" causes them to think twice before their protestations of virtue lead to active opposition to the health officer's wishes.

The following report on a referred case from the venereal disease social worker in one of the large New Jersey cities is typical. Sometimes the protestations of innocence worry the inexperienced investigator, but this matter-of-fact statement indicates that the subject did not make much of an impression on the social worker.

Dear Doctor:

In reply to your letter of the 8th, relative to a case of syphilis contracted from "Miss Mary" at 172 B. Street, I would advise as follows:

Mary R— of the above address was interviewed and vehemently denied having venereal disease. A smear was taken which proved positive and a Wassermann test was four plus. Inasmuch as she is a food handler, her permit will be revoked. We will keep her under strict supervision and advise you of any further developments.

The tactful but firm nurse or health inspector finds little difficulty in inducing such people to submit voluntarily to examination and to remain under treatment if, and when, found infected.

The letter introduces another consideration—that of the incomplete or vague name and address. Frequently physicians can obtain only a nickname or a first name, or the approximate location of a house on a given block. Obviously, such information is of less value than exact names and addresses, yet we have found that an experienced investigator can work wonders with very meager help. Physicians should be impressed with the importance of pinning their patients down to get as much information as possible, yet the physician should be encouraged to transmit whatever information he may get, even though vague. A half loaf is better than none in this instance.

Only in a score of the larger cities are venereal disease social workers or public health nurses with social training employed on the staff of the health department. In many of the smaller incorporated municipalities, a public health nurse may be available for occasional venereal disease follow-up, but in most of the suburban and rural areas no official with any health training is available. In New Jersey, unfortunately, as in New England, each township committee is constituted a board of health. Usually some corner-store clerk is designated as the executive officer, and as a rule he is innocent of any knowledge of the science of public health. The State Department of Health has adopted the policy of sending a representative to visit such rural officers when the first case is to be referred to them. They are impressed with the

necessity for secrecy and tact in dealing with suspected cases, and the state official goes with the local health officer and demonstrates the technic of the interview. Frequently these part-time, untrained officials "catch on" surprisingly well once the way is shown. The following letters tell the story of work well done by a local health officer of a New Jersey coast town.

Dear Sir:

Replying to yours of the 11th, will say that I have located the man, and compelled him to undergo an examination by Dr. H—, this city, the result being positive.

I have ordered him to report to Dr. H— as often as required for treatment, with the assurance that if any more cases are reported as being infected by him after this date, he will be locked up for the protection of the public.

Dear Sir:

Replying to yours of the 15th, asking that I have Helen R— examined, if not being treated by a physician for syphilis, she being accused by Jerry B— of infecting him. Our school nurse interviewed her, and she told her that she was under the care of Dr. D—, which he verified and says she is getting along all right. She says Jerry is a liar, for he gave it to her.

Note: The name of the woman's accuser was not given by the State Department of Health. We do not know how the Health Officer learned it.

Dear Sir:

Your communication regarding the case of Emily W—, she being reported as a source of syphilitic infection, was received at 9:00 a. m. this morning. I at once sent my assistant, Miss H— who is also the school nurse and a very efficient one, out on the case.

She reports the girl to be only about sixteen years old, very attractive, and without any knowledge of the seriousness of her condition; she will go under the care of Dr. B—, going to him this evening for the first treatment. He is the representative of the Bureau of Venereal Disease Control.

This case was disposed of at 10:30, ninety minutes after receiving your letter.

Not all rural health officials take kindly to the suggestion that venereal disease follow-up is a legitimate local health function. Some few react as did the following:

Gentlemen:

Replying to yours of the 17th inst., concerning investigation of case of Helen C—, will say we received Dr. B—'s resignation, and we have had no health board meeting, hence no action. I am not sure whether you are inferring that it is my duty to look after and investigate these cases or not. I had a little experience some few years ago and don't care for any more. However, if this is one of the requirements of me, inform me definitely and I will either do the same or resign as Dr. B— did. That is his reason for resigning. From what I hear there is a chance for cleaning up several at this house.

Other rural health officials interpret the law in their own way. For instance, the next officer, a doctor, seems not to be greatly impressed with the provision of the state law which authorizes health officials to

cause suspected persons to be examined. In this instance, the original letter asking that Mrs. Anna A— be examined as a source of gonorrhea was not acknowledged, and several of the usual follow-up letters, each a little more stern than the preceding, failed to make any impression until the following answer was received:

Dear Doctor:

All your communications, referring to Mrs. Anna A— as suffering with gonorrhea, received.

Will say I have attended the A— family as long as they have lived in town, and as she never said anything to me about having had gonorrhea, at first I thought I wouldn't have anything to do with it.

This is the reason I made no reply. A few days ago she was telling me some of her troubles, so I asked her about it. She said she had taken no treatment for it, and neither Mr. A— nor herself suffered any. I suppose by that, she hasn't it.

Others seem to think that the state regulation requiring two negative smears before the case is discharged is a little too onerous for comfort, and occasionally we get such a reaction as this:

Dear Doctor:

Your letter of recent date, relative to one Adelaide Y— received and contents noted; would say in reply that on behalf of the Board of Health of Clemens Township you are granted full authority to go ahead and make the examination of Adelaide Y— of Laurelton, as you suggested the State Board was not satisfied with the one negative report made and sent by Dr. T—.

As far as we are concerned, knowing the facts of the case, we are satisfied with the report of Dr. T— and considered the matter closed.

I am directed to say to you that you may make the examination if you wish on your own responsibility and at your own expense.

By and large, the local health officials of New Jersey respond readily and efficiently to the request that suspected carriers of venereal disease be examined and placed under supervised treatment. In other words, venereal disease case finding is a practical procedure, for it is producing results in New Jersey, where conditions are comparable to those of the New England States. By this method it is possible to detect the persons who are the worst offenders in spreading venereal diseases, and if the worst offenders are taken care of the occasional offender will be less dangerous.

It may be assumed that, although gonorrhea and syphilis are very prevalent diseases, the number of persons suffering from these diseases in an infectious stage and who are actively engaged in spreading the infections to others is not very great in any one community. Sooner or later each will infect a person who will go to a physician or clinic for treatment. With coöperating physicians and active health departments, it is reasonable to assume that the proposed method will be

effectual in stopping the important avenues for the spread of venereal diseases.

Important as is this procedure, other means of discovering cases, of course, cannot be neglected. Voluntary and other official agencies can assist the health officer in detecting and referring for treatment suspected venereal infections among persons presenting other social problems. The police department can assist by having examined all persons arrested on charges involving sex offenses, and health officials are justified in demanding that the police repress all open prostitution. Industrial medical departments and employment agencies are another fertile source for the detection of unrecognized cases, and the infant hygienists will find important leads from stillbirths, neonatal deaths, and other conditions where congenital syphilis can be detected. The details of these supplementary venereal disease control activities are too involved to permit of discussion here. Some of them are described in two earlier papers on venereal disease case finding.¹

If we offer treatment only to those who seek it voluntarily, if we place too much faith in the influence of sex information upon human behavior, if we think of sexual promiscuity in terms of vice districts, and neglect that "gold mine" of information—the recently infected venereal case now under treatment—we are neglecting the most effective method of attacking today's most dangerous preventable diseases—gonorrhea and syphilis.

Promotion of Physical Education in Italy

A recent royal decree provides an annual appropriation of 10,000,000 lire (beginning with the fiscal year 1928-29) for the recently established National Bureau of Physical and Moral Education of Young People. The decree also gives the bureau charge of the physical education of children in elementary public schools and in all private schools and authorizes it to establish normal schools for the training of teachers of physical education. The establishment of such a school in Rome has already been decided upon, and 400 applications for admission have been received.—*Rassegna della Previdenza Sociale*, Rome, Jan., 1928, p. 101.

Study of Urban and Rural Tuberculosis Death Rates in New York State

JESSAMINE S. WHITNEY

Statistician, National Tuberculosis Association, New York, N. Y.

IS THE rural death rate from tuberculosis higher and is it declining at a slower pace than that of the city? This question has been the subject of a good deal of discussion ever since it was raised by Dr. Allen K. Krause, Editor of the *American Review of Tuberculosis* in the March, 1926, issue of that journal. An answer to the question has been attempted in the study outlined in this article.

New York State's figures are used as a basis of comparison because they are fairly typical and also because a detailed analysis of the records was made possible by the New York State Department of Health. It is probable that any other state in the Union where there are a number of sanatoria located in rural territory will find a similar comparison. Dr. Krause pointed out that between 1913 and 1918 the rural tuberculosis rate of New York State was below the urban rate, but that during 1918 the rural line crossed the urban, and from that time until 1925 the rural tuberculosis rate in New York State had exceeded the urban rate and in 1924 reached almost twice the urban rate.

To arrive at any understanding of the significance of these figures, or the possible reasons therefor, one must be somewhat familiar with the methods used in collecting the data on which the death rates are based. The usual custom is to consider as a part of the mortality of any district all deaths which occur in that district whether of residents or non-residents. This plan is in operation in New York State and therefore recorded tuberculosis death rates are not an accurate measure of the amount of tuberculosis in any community, but show only the number of cases terminating fatally in that territory.

Then again it is germane to a discussion of this sort to know exactly what is meant by "urban" and "rural." The former term usually connotes a busy city and the latter a pastoral scene dotted with farm-houses. That is all right for literature, but in statistics clearly defined limits must be drawn since we are dividing all territory in New York State into the two classes.

Up to the year 1922 the New York State Department of Vital Statistics classified as urban all cities and three large villages, making the dividing line of population 10,000; that is, those cities and villages

having a population of 10,000 or over were classed as "urban" and all other territory was classed as "rural."

In 1922 the classification was changed and the dividing point in population between urban and rural was placed at 2500. All incorporated villages of 2500 or more population and all cities were included under the heading "urban," and the rest of the state classed as "rural." It is a question whether a village of 3000 should properly be considered "urban"; but it is equally questionable whether under the prior classification a village of 9,500 could correctly be considered "rural." In the graphs made by the New York State Department of Health for Dr. Krause's editorial the figures were kept consistently according to the 10,000 population division throughout, although a change in actual practice occurred in the middle of the period studied.

Dr. Krause sums up the picture as shown by the graph as follows:

This trend, it is plain, is a mounting ratio of rural to urban tuberculosis, which has been going on for at least 13 years, to reach a point at present which puts rural well ahead of urban mortality. During the last 5 years the trend has been greatly accentuated, as it expresses, no doubt, a static or slightly rising rural rate set against an accelerated urban decline Were this the portrayal of merely an addition to rural columns of decedents transferred and subtracted from their urban residences, its uniformly expanding character could be explained only by the condition of an ever increasing number of deaths of city dwellers in the country.

Had Dr. Krause stopped here he would have had the answer. But he chose to go further and to somewhat repudiate this explanation by quoting from Dr. Eichel, then Statistician of the State Department of Health, to the effect that the annual number of non-resident deaths formed an almost constant percentage of the recorded deaths, so that the general trend of mortality was not affected. When Dr. Eichel made that statement he was discussing tuberculosis death rates in the 10 largest cities of the state, and for them the statement is undoubtedly true. It is not true for the situation in rural territory.

To arrive at such a positive statement as the above we accepted, to a limited extent, Dr. Krause's challenge for an analysis in greater detail of the vital statistics of New York State. The main point at issue, already defined by Dr. Krause, is whether the rural tuberculosis rate represents a mortality of decedents actually residents of rural territory. To ascertain this a study was made from information contained in the death certificates themselves.

The years covered were 1917 to 1924 inclusive, since prior to the year 1917 the vital statistics records were not available in the same forms as for later years. The records of the years 1925 and 1926 were in process of current tabulation and compilation and could not be made available for the purposes of this study.

Since the classification for "urban" and "rural" had been changed in 1922 to a division point of 2500 population, it was felt that either the former or the latter classification should be carried throughout, as changing the areas in 1922 might seriously vitiate the significance of the data. We have chosen to use the later classification throughout; that is, to consider as rural all unincorporated territory and all incorporated places under 2500 population. This certainly more clearly defines "rural" territory, than the former classification even if the remaining territory is not so clearly "urban," for it is with the changes in rural conditions with which we are chiefly concerned. This will account for the discrepancy between the official figures and those given in this study, although the total tuberculosis deaths for each year in each county and for the state as a whole will of course be the same as the official figures.

In the whole of New York State there were in the 8 years under consideration approximately 103,000 deaths from tuberculosis, of which over 16,000 occurred in rural territory. To discover from observation of the original death certificates themselves the usual place of residence of rural decedents and the time of their residence at the place of death was the method of this study.

It comprises data on 16,347 deaths from tuberculosis in rural territory in New York State during 8 years, 1917 to 1924 inclusive. Of this number 7,967 deaths or 49 per cent, were deaths of non-residents of the districts in which the deaths occurred. But this figure of 49 per cent is an average figure for the 8-year period. As a matter of fact, the percentage of non-resident tuberculosis deaths in rural New York in 1924 was 57, an almost steady per cent increase being shown from 1917 when the corresponding figure was 41 per cent.

From the careful analysis of the data there can be but one answer to the question as to the cause of the higher rural tuberculosis rate; namely, the deaths occurring in sanatoria and other institutions located in rural territory. In the very summer of 1918 when according to Dr. Krause's article the rural rate rose above the urban rate, the United States Army General Hospital No. 8, with 1000 beds for returning tuberculous soldiers was established in the rural part of Orange County. Although it was in operation only 2 years it accounts for about one-third of all non-resident deaths in Orange County in the entire 8 years. The large Monroe County Hospital, Loomis Sanatorium in Sullivan County, Onondaga County Sanatorium, the Samuel W. Bowne Memorial in Dutchess County, to cite only a few of the many, are all located in rural territory.

In 1917 there had been established in rural New York State 24

sanatoria with a capacity of 2868 beds. By 1923, there were 41 sanatoria in New York State in rural territory with a capacity of 4511 beds, a 57 per cent increase of rural beds in 6 years. There was almost exactly twice that increase in deaths in rural tuberculosis sanatoria in the same 6-year period; viz, an increase of 115 per cent.

Only 30 per cent of non-resident rural deaths were in private homes, 54 per cent were in tuberculosis sanatoria and the remaining 16 per cent in what were classed as "other institutions" although most of them were in tuberculosis wards or divisions of general hospitals. There were a few scattering deaths at county farms and in so-called "health farms." If the tuberculosis sanatoria deaths and those in "other institutions" are grouped, as they may properly be, 70 per cent of all non-resident deaths in rural territory are in tuberculosis institutions. But this figure of 70 per cent is the average for the 8-year period. It ranges from 61 per cent in 1918 to 80 per cent in 1924.

Let us now summarize the facts for 1924, the latest year of the study. Of all the tuberculosis deaths in rural territory 57 per cent were of non-residents of the territory in which the death occurred, and 80 per cent of all these non-resident deaths occurred in tuberculosis institutions.

To make clearer the picture of the migratory character of the tuberculosis decedents in rural territory, a classification was made of the number resident at the place of death less than 3 months prior to death, and it was found that 44 per cent of the non-resident deaths during the 8-year period fell into this class. For 1924, the last year of the study, the corresponding figure was 48 per cent. The average length of residence in the district where death occurred was 6.7 months. This figure ranged by counties from 3 months in Tioga County to 8½ months in Essex County, one of the famous health resorts of the state.

For a fuller knowledge of the rural situation, it was necessary to know from what sources the migration to rural territory had been made. Obviously some of it might come from other rural territory in the state and be properly a part of the rural rate. This part of the study is perhaps one of the most important phases of it. It was found that 10 per cent of the non-resident rural tuberculosis deaths were of persons who resided outside New York State; 15 per cent were of non-residents (clearly specified on the death certificate as having resided less than a year in the district) but for whom the usual place of residence was not entered; and the remaining three-fourths were residents of other sections of New York State, 62 per cent residing in urban and 13 per cent in other rural New York territory.

If the 15 per cent for whom the residence was not given be distrib-

uted according to the ratios found for known residence the figures would then show that 73 per cent of rural decedents came from urban territory, 15 per cent from other rural territory, and 12 per cent from outside New York State. The 12 per cent from outside New York State are, as might be expected, found almost exclusively in Essex, Sullivan and Orange Counties, health resorts famous throughout the country. The United States Army General Hospital in Orange County furnished one-sixth of the deaths of persons whose homes were outside New York State.

The question as to the greater propensity for migration in search of health between male and female sufferers from tuberculosis is settled by the fact that during 8 years in New York State the percentage of male deaths to all non-resident deaths in rural territory was 61. The lowest percentage of male deaths was found in Schuyler County (25 per cent) and the highest in Orange County (81 per cent), the county where the United States Army General Hospital was situated. Even with the figures for the latter county excluded the males were 60 per cent of the total.

The total non-resident deaths in rural territory were classified into broad age groups: under 15, 15 to 24, 25 to 54, and 55 and over. No facts of especial significance were brought out through this phase of the study. As might be expected, 86 per cent were at the ages 15 to 54, only 3 per cent children under 15, and 11 per cent older persons, past 55.

The tuberculosis death rates for urban and rural New York State (uncorrected) based on a 2500 population division are given in Table I.

TABLE I

Year	Urban	Rural	Year	Urban	Rural
1917	140.6	134.7	1921	80.0	108.4
1918	135.3	127.0	1922	75.6	106.7
1919	169.8	119.0	1923	78.0	101.2
1920	93.2	117.8	1924	76.7	94.2

Even these uncorrected recorded rates show a steady decline in the rural tuberculosis rate as in the urban, which has been continuous for at least 8 years.

On the basis of the findings of this study we can correct those rates year by year by deducting from the rural mortality the percentage of non-residents found among the decedents for each of those years. A correction must also be made for non-residents from other rural territory whose mortality properly belongs to the rural rate. When these two corrections are made the rural rates for the 8 years are as follows:

The corrected rural rates eliminating non-residents fall far below the corresponding urban rates and the trend is downward. (See Figure I).

TABLE II

New York State			New York State		
Year	Tuberculosis rural rate uncorrected	Corrected for non-residence	Year	Tuberculosis rural rate uncorrected	Corrected for non-residence
1917	134.7	90.1	1921	108.4	59.5
1918	127.0	85.8	1922	106.7	58.8
1919	119.0	73.3	1923	101.2	57.0
1920	117.8	68.4	1924	94.2	48.9

Rates

FIGURE I—Urban and Rural Tuberculosis Death Rates with Rural Rates corrected for Non-residents. New York State, exclusive of New York City, 1917-1924.

To this the question may be raised: that is all right for a correction of non-residents in rural territory, but how about the correction of rates in urban territory? Are there not equivalent percentages of tuberculous persons who go to urban institutions and die there, who properly belong in rural territory?

Fortunately this matter has already been answered for us by two studies. In 1922 Dr. Otto Eichel then Director of the Division of Vital Statistics in the New York State Department of Health, made a

correction of all tuberculosis deaths for residence in which he charged all tuberculosis deaths to the district in which the decedent resided when the disease began. His findings were referred to by Dr. Krause.

Dr. Eichel found that in correcting the tuberculosis death rates, not only the New York City rate was raised from 3 to 5 points but that the adjustment for the 10 largest cities in the state showed that in all but 2 the rate after correction for non-residence was higher than the usual recorded rate.

We have still another study just completed by Dr. J. V. De Porte, Director of the Vital Statistics Division of the New York State Department of Health. For the year 1926 all tuberculosis deaths in New York State were re-allocated to the districts which were the usual places of residence of the decedents, and Dr. De Porte's figures show that on this basis the rural and urban rates change places; that is, that the corrected urban rate is even farther above the rural than the rural exceeded the urban in the recorded rates. The actual figures are as follows:

TUBERCULOSIS DEATH RATES IN NEW YORK STATE PER 100,000 POPULATION, 1926			
Urban		Rural	
Recorded	Corrected for Residence	Recorded	Corrected for Residence
70.4	83.2	87.5	59.4

Dr. De Porte's figures for 1926 show that the actual rural rate is only two-thirds the recorded rate, while the actual urban rate is 18 per cent higher than the recorded urban rate.

SUMMARY

The usual recorded mortality rates from tuberculosis for rural and urban territory are fallacious in that they do not represent the actual mortality of the various sections.

Rural tuberculosis mortality rates are controlled by the deaths of persons in tuberculosis institutions. In New York State the number of beds for tuberculosis in rural territory have increased 57 per cent in the last 6 years. The increase in deaths in rural tuberculosis sanatoria has increased 115 per cent in the same time.

Fifty-seven per cent of persons who die in rural territory are non-residents of that territory. Eighty per cent of all non-resident rural deaths occur in tuberculosis institutions.

When an actual analysis of tuberculosis deaths is made and non-residents are allocated to their home area the rural tuberculosis rate becomes only two-thirds the recorded rate while the urban rate is increased by 18 per cent.

The actual rural tuberculosis rate is considerably lower than the urban in New York State and is declining.

Advancement in Mosquito Control in the United States and Canada*

BY questionnaire, the committee obtained information on mosquito control activities from the health departments of 42 states and provinces in North America and from the territory of Alaska.

These units are grouped in 4 classes and under each classification, a summary of the activities of each state or province is given.

GROUP No. 1—States and provinces in which mosquito control operations are being carried on:

New Jersey—Control of salt marsh mosquitoes continues to be the greatest problem. Malaria mosquitoes have appeared only rarely in two or three counties, principally in unprotected areas. Salt marsh ditching has gone on; several million feet (when figured on a 10" width basis) are being cut each season, with the result that this phase of work approaches completion in a number of counties. Ditch cutting and cleaning machines are in use in several places; Hudson County employs electric pumps for drainage purposes; mowing machines have been used in several counties to clean up ditch edges and to afford access to swamps; tractors have proved helpful in transportation of oil, and power oil sprayers are in use. Due to dissatisfaction with the spreading, lasting and killing properties of fuel oil, the State Experiment Station will coöperate with oil companies to produce a more suitable oil. The State Experiment Station has also developed a new mosquito trap.

County-wide control was continued in 10 counties operating under the State Mosquito Control Laws and it is expected that 2 more counties will soon engage in this work in the same manner. Although the season was favorable for mosquito production, annoyance in the metropolitan districts was but slight. Where salt marsh mosquitoes have been largely eliminated during the last 10 years from New Jersey coastal areas, there has occurred an annual average increase in taxable values of 75 per cent more than where the mosquitoes are still present.

Illinois—Malaria prevails in the 12 southern counties and pestiferous mosquitoes are more or less annoying throughout the whole state. *Culex* production in sewage polluted water courses around Chicago has been enormous. In the south, 3 additional cities inaugurated

* Abstract of Report of the Committee on Mosquito Control, delivered before the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

control work and numerous lakes and ponds were stocked with minnows. In sparsely settled swampy areas, screening, destruction of adult mosquitoes and quinine sterilization are practiced. To determine the economic importance of predominant species, and having in view the control of all annoying mosquitoes, some experimental work was done in the northern part of the state. Around Chicago and its environs, intensive control work resulted in greater benefits; for through the efforts of a number of official and semi-official agencies, more than 20 cities and towns successfully engaged in abatement work. Several miles of channels were opened up to correct obstructed flow in rivers and creeks polluted with sewage from the Chicago area. A number of municipalities raised funds by popular subscription for interior control work. The outstanding feature in mosquito control work this year was the enactment of a law in Illinois providing for creation of abatement districts in communities having a population greater than 300 and for the collection annually of funds by taxation not to exceed one mill on each dollar of taxable property. Application has already been made for one district in the south and three in Cook County, embracing 50-odd municipalities. It is understood to be the plan that such abatement districts will take over all mosquito control work within their respective boundaries.

Texas—Of the 254 counties in the state, about 200 have a mosquito problem with approximately 100 of these reporting malaria. The state authorities are confronted with the problem of spreading control work over a very large area at an increased per capita cost. Systematic control is conducted in some 130 towns, though not all have full-time programs. To those towns which have previously had control operations functioning, the state authorities give only certain supervision and assistance in reviving intensive field work during the mosquito breeding season. Under this limited plan the state health department is enabled to extend its field of operation. Much has been done to eliminate mosquitoes and malaria in certain areas of concentrated population, but little has been done in rural sections. Control operations along the Mexican border have been continued by local communities. Organized control work has reached directly and indirectly approximately 2 million people, which is about 40 per cent of the state's population.

Louisiana—Although mosquitoes are present all over the state and certain sections are malarious, it is stated that the mosquito nuisance is less, that there have been no outbreaks of mosquito-borne diseases, and that the malaria rate seems to be continuing a gradual decline. The state health department has continued to make surveys and submit

plans for and cost estimates of control work. As part of the post-flood sanitation program the work of screening 600 homes of known malaria carriers is being carried out. This work is being done at the expense of the American Red Cross and under the direction of the U. S. Public Health Service. Data collected to compare mosquito bars with screens indicated that more than half of the mosquito bars were not mosquito proof. Although screens give greater protection, the cost of using them, based on a 4-year period and as compared to mosquito bars, was found to be about the same.

Mississippi—Three species of *Anopheles* are to be found here, and *Aedes sollicitans* exist along the coast. The receding waters from the flood created innumerable *Anopheles quadrimaculatus* breeding areas. The 22 full-time county health departments have accomplished considerable control work and 4 additional cities have appropriated special funds to engage in abatement work. The state has maintained its system of advising and supervising. With the aid of the American Red Cross and the U. S. Public Health Service, approximately 3400 homes were screened as a part of the flood sanitation program. The outstanding feature this year is the development of increased interest on the part of the citizenry in mosquito control work.

Alabama—Anti-malaria work and the control of pestiferous mosquitoes are regular functions of the 32 county health units which serve 65 per cent of the population. The outstanding feature of the work is the prevention of new foci looking to the time when the old foci will be eliminated and malaria controlled. The permit system for impounding water is a primary tool of control and places the burden on the property owner where it belongs. Failure to secure results brings a revocation of permit.

Railroad Coöperation in Texas, Louisiana, Arkansas and Missouri—The St. Louis-Southwestern Railroad, Missouri Pacific Railroad and the Chicago, Rock Island and Pacific Railroad all extended their malaria control activities in 1927 in these states. A number of communities took advantage of the coöperation offered by the railroads and inaugurated control measures. Engineering personnel of the railroads lent material assistance during the flood period in planning and effecting anti-mosquito campaigns.

California—Data for this year were not received by the committee. Salt marsh mosquitoes exist along the coast and *Anopheles* and *Culex* inland. Malaria is prevalent in the Sacramento Valley. There is every reason to believe that the usual activities of the 17 organized abatement districts continued during the year.

Virginia—In the Eastern section of this state a malaria mosquito

problem exists, and salt marsh mosquito production along the coast remains unabated. Control work, limited almost entirely to the malaria phase, was continued in 27 towns. A study of salt marsh breeding was made in the area of Hampton Roads and a control commission appointed in anticipation of the creation of a district there. At Quantico, dusting with Paris green by airplane was carried on throughout the season.

South Carolina—Anopheles control work was conducted in 4 counties by permanent health units under state supervision, and 7 drainage districts established at the joint expense of the International Health Board and the counties, have been maintained and have proved effective. Financial conditions preclude the establishment of 15 additional drainage districts on which surveys have been made. Coöperation has been established with the state highway authorities for the elimination of borrow pits, and at Bamberg, Paris green dusting by airplane was successfully tested. Impounding water regulations were rigidly enforced. State assistance was given to 23 towns in the control of pestiferous mosquitoes. As an educational measure, lecture courses were established in 3 universities in the state.

North Carolina—Malarious mosquitoes are present in 13 of the eastern counties. Such control work as is done is conducted from the standpoint of disease prevention. Where required, control operations were conducted by county health departments under the supervision of the state. Two counties have been able to report a reduction of malaria of approximately 60 per cent after 3 years' intensive work. A study of the influence of impounding water upon malaria incidence is being conducted by the state.

Georgia—Control work this year by the state comprised service to 40 municipalities and was directed against all species of mosquitoes and toward enforcing regulations relative to the impounding of water.

Florida—Mosquito breeding in the mangrove areas along the east coast received special attention and beach cities gave considerable thought to the curtailment of mosquito production in adjacent areas. The control district of Indian River County spent \$4,000 and supported a bond issue of \$100,000, which however, has not yet been validated. Seventeen cities serving one-quarter of the population of the state engaged in concentrated work with good results. Several marsh areas were transformed into lakes. Three counties engaged in salt water mosquito control work. The women's clubs were active in educational work. Outstanding features include the adoption of machinery for oiling, the arousing of much public interest and coöperation, the adoption of the method of charging cost against land benefited

in some sections, and the elimination of malaria and dengue fevers in Daytona Beach.

New York—The only organized work in the state is confined to sections of Nassau County and New York City and is conducted by the Nassau County Mosquito Extermination Commission and the New York City Board of Health. Control covers the entire county of 307 square miles with 20,000 acres of salt marsh, 2 cities and 50 villages. The outstanding feature of the work is the reduction of malaria from 476 cases in 1916 to an average of 2 cases for the past 6 years and the development of machinery for catch basin spraying. The problem in New York City is principally one of annoyance. Construction of new roads without proper culverts established new breeding places. Oiling operations by truck were extended and a portable pump used for draining most areas which could not be filled.

Connecticut—Interest in mosquito control has increased during the last 2 years, although the problem here is limited to non-disease carrying mosquitoes. Salt marshes in 3 towns were ditched, using both public and private funds, and other acreage previously ditched was maintained either under state supervision or through local assistance. In New Canaan oiling proved satisfactory.

Rhode Island—In 1925 and 1926 the state appropriated \$30,000 per year to be available to municipalities on a 50-50 basis for mosquito control work. However, in 1925, 31 per cent of this amount was withdrawn and in 1926, 23 per cent. This year only \$15,000 was appropriated but nothing was withdrawn. This decrease in expenditures indicates a parallel decrease in sentiment for mosquito control. The State Commissioner of Public Health, believing the problem one worthy of attention, has endeavored to create favorable public sentiment.

Massachusetts—The principal problem in this state is that of salt marsh mosquitoes. The only control work effected in recent years has been that which resulted indirectly from the operations of the Massachusetts Drainage Board which is conducted for the purpose of improving agricultural areas.

Pennsylvania—The problem is reported as being local in nature, of minor importance and handled by local authorities.

Kentucky—The only work carried on this year was in connection with the Mississippi River Flood and consisted of draining and oiling pools. The State Board of Health has been unable to organize anti-mosquito work on account of insufficient personnel.

Tennessee—Malaria problems lie principally in the western part of the state covering an area some 100 miles square. *Culex* are also

found in this and several other sections. Although general mosquito control work was carried on in some 20 cities and towns, malaria control is the principal activity and was conducted on a county-wide basis in 5 of the western counties with the most highly concentrated work in Shelby County. A quantity of oil for use in 3 of those counties flooded by the Mississippi River overflow and some \$5,300 for screening was supplied by the National Red Cross. Activity is also reported in 4 cities in the central part of the state. Paris green dusting and *Gambusia* play an important part in control operations.

Missouri—Malaria is present to some extent in all parts of the state but is an important factor principally in 7 counties in the southeasterly section, which also applies to the pest mosquito. Due to insufficient personnel and funds control plans are developing slowly, the present activities being limited to educational campaigns.

New Mexico—Anopheles are found in only two localities although mosquito breeding is common along the Rio Grande. Malaria prevails in Dona Ana County and in a small section north of Santa Fe. Only one city has undertaken systematic control work with money obtained by popular subscription. Airplane dusting is to be considered next year.

Idaho—Some pool drainage was done by a few cities. Malaria is not a factor.

Maryland—Survey of one summer resort and town was made and oiling operations were conducted in another town. The problem is principally one of pestiferous mosquitoes.

West Virginia—Occasionally there are complaints from communities because of mosquitoes but the causes of such complaints are easily determined and corrected.

Dominion of Canada—Mosquitoes are reported throughout the Dominion and have been found in large numbers in several sections. It appears that malaria is not a factor. The Department of Agriculture is active in control work.

Nova Scotia—No organized control work has been attempted.

New Brunswick—Control measures have been of an incidental nature, such as the drainage of ponds and swamps.

Quebec—In 1926 a swamp in Montreal was given one application of oil, but operations were not entirely effective due to the extent of the problem and the lack of funds. It is understood that this work is to be continued this year.

Ontario—The city of Ottawa made an appropriation in 1926 for preliminary control work by local boards of health. The invasion of mosquitoes from outlying areas somewhat nullified the work. A mix-

ture of oil and caustic soda gave good results and dusting with powdered derris root was found to be effective. A small amount of money was spent for drainage and oiling this year.

Manitoba—The Winnipeg Anti-mosquito Campaign Committee gives coöperation with some other agencies and is carrying on an active and effective control campaign.

Saskatchewan—Health authorities in this province have said that malaria was not considered in their program and therefore control work was not inaugurated by them.

Alberta—At Banff, the Department of Agriculture has been successful in control operations using oil and gambusia. The Provincial Health authorities have done no such work.

British Columbia—In this Province there is a rich agricultural area where spring and summer freshets establish a 14,000-acre breeding area. The Department of Agriculture recommends permanent diking and draining.

GROUP No. 2—States in which the mosquito control problem exists with no control being done:

Kansas—Mosquitoes of the pestiferous species are present but were not so prevalent as when conditions for breeding were more favorable. The State Department of Health has sponsored a mosquito radio talk.

Indiana—Although no organized work is carried on, extensive drainage operations conducted for agricultural purposes and real estate developments have indirectly resulted in good.

Delaware—Mosquitoes of the irritating varieties are present in abundance but the problem of control would embrace 80,000 acres of salt marsh in addition to the usual fresh water breeding places. An educational campaign is contemplated as a preliminary step to active work.

Iowa, Wisconsin, Minnesota, Wyoming—It appears that malaria is not a factor in any of these states and that no organized control work has been instituted.

Oregon—Due to a late high tide, mosquitoes were more abundant this year than usual. There was also a slight increase in the number of cases of malaria although the total was not high. Efforts to secure protective legislation have not been successful.

Washington—It appears that the mosquito problem is not of sufficient weight to merit the expense of control work.

Alaska—Mosquito production in the interior is exceptionally large. The population of the territory is so small in comparison with the area

that control is almost economically impossible. It is understood that there is no malaria problem.

GROUP No. 3—States claiming to have no problem:

Maine, New Hampshire, Vermont, Ohio, Michigan, North Dakota, Montana and Colorado.

GROUP No. 4—States from which data are not available:

Oklahoma, Arkansas—In these two states the records indicate a malaria problem.

South Dakota, Nebraska, Utah, Nevada and Arizona—It is believed that malaria prevails to some extent in some of these areas with more or less trouble from pestiferous mosquitoes.

There has been a marked reduction in mosquito production generally since last year. It appears that there is a decided increase in sentiment for mosquito control work in North America and that such work is being directed more and more against all species of mosquitoes. Machinery is coming into further use in extensive control work and as a means to an end, enabling legislation is being enacted in additional states.

In view of the very encouraging progress recorded the committee limits its recommendations to continuance of progress in this important adjunct of public health engineering: the enlarging of abatement work of a permanent nature; securing the fullest possible coöperation of the public through the formation of state and local anti-mosquito associations, radio publicity, motion pictures, etc.; seeking favorable legislation where none exists and recommending the adoption of appropriate regulations in roadway and other public developments whereby mosquito breeding places will be built-out instead of built-in.

Course in Psychiatric Work

A one-year postgraduate course in welfare work in Germany with mentally abnormal children, open to physicians, teachers, clergymen, and child welfare workers, was to be started on January 1 of this year under the auspices of the German Association for Psychiatric Work among Children. *Zeitschrift für Schulgesundheitspflege*, Leipzig, 12:559, 1927.

Montana's Laboratory for the Study of Insect-Borne Diseases

R. A. COOLEY

Secretary, Montana State Board of Entomology, Bozeman, Mont.

PROBABLY there does not exist another research laboratory like the one of the Montana State Board of Entomology now nearing completion at Hamilton. The field of work as laid down in the Act which created this board in the year 1913, is "to investigate and study the dissemination by insects of diseases among persons and animals, said investigation having for its purpose the eradication and prevention of such diseases," and the new laboratory is designed and equipped, so far as is possible within the available fund, to perform the necessary studies connected with insect-borne diseases. The Act authorizing the erection of this laboratory, signed by Governor Erickson on March 16, 1927, appropriated the sum of \$60,000. The building is a brick faced, reinforced concrete structure of three stories, 40 feet by 66 feet on the ground. A one-story wing 88 feet in length is attached to the west and is designed for the care of stock laboratory animals. The building is made without a basement in order that it may be as sanitary as possible, and to have as few places as possible where insects or rodents may hide away. The construction throughout is such as to avoid cracks and sharp corners. The boiler burns oil and is automatic and certain of the rooms have automatically controlled temperatures. While the building is planned generally for the field of medical entomology, and closely associated lines, it is laid out particularly for the needs immediately before the state. The common wood-tick of the region, *Dermacentor andersoni* Stiles, and the diseases of man and the losses in live-stock of which it is the cause, constitute the immediate problem.

The work on Rocky Mountain spotted fever is being conducted under an informal plan of coöperation between the U. S. Public Health Service and the Montana State Board of Entomology. At the present time the U. S. Public Health Service is concerned mainly with a further study of the Spencer-Parker vaccine. This vaccine, made from the bodies of infected ticks, was originated two years ago at the old, improvised laboratory at Hamilton and at the Hygienic Laboratory at Washington, D. C., by the two U. S. Public Health Service workers whose names it bears. It now has been used on about 4,000 persons in Montana, Idaho and Wyoming, with uniformly encouraging results. The U. S. Public Health Service is also giving attention to the study of

the organism of spotted fever, *Dermacentroxenus rickettsi* Wolbach, and other organisms found in ticks; characteristics of the virus of spotted fever, with particular references to differences in ticks and in various laboratory and wild mammals; relationships of the rabbit tick, *Hacmaphysalis leporis-palustris* Packard, in the spotted fever complex, tularemia, and tick paralysis in man and domestic animals. Some years ago the entomologist of the State Experiment Station at Bozeman, in coöperation with Dr. W. D. Hunter, Dr. F. C. Bishopp and Dr. W. V. King of the U. S. Bureau of Entomology at Washington, worked out the life history and host relationships of the wood-tick. Since that time the entomologist of the Board of Entomology has done further work on its biology, particularly with reference to its reactions to temperatures. During the past year the entomologist has been engaged in a study of the French tick parasite, *Ixodiphagus caucurtei* Du Buysson, introduced into Montana with the assistance of Dr. Brumpt and Dr. Larrousse of the University of Paris, and Dr. S. B. Wolbach of the Harvard Medical School of Boston. Particular emphasis is to be given to the work on this parasite during the next few years and an effort will be made to find other parasites, particularly in Africa.

The U. S. Public Health Service is represented in Montana by Dr. R. R. Spencer, officer in charge, and by Entomologist R. R. Parker, Special Expert. The State Board of Entomology is *ex officio* and composed of Dr. W. F. Cogswell, Secretary of the State Board of Health, *Chairman*; Dr. W. J. Butler, State Veterinary Surgeon, *Member*, and R. A. Cooley, State Entomologist, *Secretary*.

A feature of the spotted fever studies in Montana is that they are planned and carried out with careful reference to field conditions. It is for this reason that the new laboratory was erected at Hamilton in close proximity to regions where Rocky Mountain spotted fever is found. Field conditions may be thus easily studied, materials for study may be brought in, and parasites may be bred and quickly liberated.

Laboratory work on spotted fever has always been dangerous for the workers. Up to the time that the Spencer-Parker vaccine was developed there had been 4 cases of laboratory infection with the disease in Montana (3 at the field laboratories and 1 in Helena). All of these cases were fatal. Since we have had the vaccine there have been 7 laboratory cases and 6 of these have recovered. It is now indicated that the vaccine gives full protection against all strains of the disease excepting the more virulent one in the region near the laboratory, and sufficient protection in the majority of cases to insure recovery from infection with the more virulent strains. It is hoped the new laboratory with its modern conveniences will afford much better protection for the

workers than was possible in the one being abandoned which was a vacated schoolhouse.

The new building provides an incinerator for the disposal of dead animals and all waste; a specially adapted laundry and drying equipment for the cleaning and drying of the numerous cloth bags used to confine the ticks on laboratory animals; dressing, locker and shower rooms for the use of workers, who are expected to make a change of clothing on coming from the field and on leaving the laboratory; a shop for the making of cages and other equipment; a poison room for mixing and drying poisoned grain to be used in the destruction of certain rodents; and quarters for the custodian. A special feature of the equipment is a series of three refrigerator rooms cooled by a Frick ammonia machine. These rooms are cork walled and are automatically maintained at 40° C., 40° C. and 0° C. respectively. In these rooms are fifteen thermal cabinets automatically maintained at graded temperatures ranging from 0° C. to 37° C. These cabinets will be put to a variety of uses including storage and incubation of cultures, virus, and vaccine, and experimental work on ticks and parasites.

During the season of 1928 we hope to rear and liberate at least 1,500,000 parasites, which involves the holding of a large number of parasitized ticks, and we have found that within certain limits we can bring them out when we want them by varying the holding temperature.

The building provides several rooms in which laboratory animals such as guinea pigs and rabbits, and wild rodents such as ground squirrels, mountain rats and wild rabbits of various kinds, will be held in cages stacked in steel frames. The production of vaccine in quantity involves the feeding of a very large number of infected ticks, as well as numerous tests on guinea pigs. Many of the experiments on the virus and the studies of the organisms require the use of laboratory animals. In the parasite work it is necessary not only to parasitize the ticks while they are on animals but also to rear the ticks which are to be parasitized. To prove that parasites have been established in the experimental field areas and determine the percentage of parasitized ticks, wild rodents must be trapped and held in cages until the ticks drop off.

It is thus necessary to hold a very large number of animals in cages in the screened and guarded laboratories. This requires the daily feeding of animals, often the taking of their temperatures, and at all times the keeping of the cages and rooms in a clean and sanitary condition.

There are also provided two general laboratories equipped with facilities for chemical and bacteriological studies. For the grinding of infected ticks and further preparation of the vaccine, a special room with suitable facilities is provided. There are also furnished office and

record rooms and a photographic room. The rabbit hutches in the animal wing deserve special mention as they are made in keeping with the established practice of rabbit breeders in the Northwest. These hutches are built in four tiers facing a hollow square or court. While the four walls of the building are complete, the roof is left off in the portion over the court thus practically exposing the animals to the open air, which exposure growers have found keeps rabbits in a healthier condition. The guinea pig room is of tighter construction and is given a small amount of heat. A root cellar is under this room.

Rocky Mountain spotted fever occurs, in addition to Montana, in the following states: Idaho, Wyoming, Utah, Colorado, California, Nevada, Washington, Oregon, North Dakota and South Dakota. In spite of this general distribution in the Northwest the people of the United States rather generally look upon the disease as being peculiar to Montana. This is due to the fact that most of the investigations have been conducted in Montana, and also to the fact that there exists an area in western Montana where the disease is more virulent and fatal than elsewhere. In western Montana, particularly, spotted fever has been looked upon as a "mystery disease." The brilliant work of Dr. H. T. Ricketts removed some of this mystery and pointed the way for further study. The excellent work now being done by the U. S. Public Health Service is further explaining the peculiarities of the disease.

Including the highly trained specialists and their helpers, in this country and in other countries, there have been 7 deaths from laboratory infection with the Rocky Mountain spotted fever. This is probably a record. These deaths have contributed an air of romance to the disease and popular writers have found spotted fever in Montana a fertile subject. Much or most of what has been written is true if taken as separate statements. But selected statements set forth without telling all of the facts, and made in highly colored language, have created a false impression, which is hurting the State of Montana both in its reputation as a place of residence and also economically.

The Board of Entomology has pursued a policy of fearless truth telling, believing this to be the best way to overcome an unreasonable fear that some persons seem to have. Spotted fever does occur in Montana rather generally though there is a small total of cases. There were 36 in 1927, and this number compares favorably with many other diseases. Ticks are common in many parts of Montana but ticks are common in places all the way through to the Atlantic Ocean.

The State of Montana expects to continue its studies of the tick and spotted fever and the new laboratory here described may be taken as an earnest of the state's desire to remedy the situation which exists.

Pathology, Prophylaxis and Treatment of Subtertian Malaria

IAN MACKENZIE, M. D.

International Petroleum Company, Ltd., Peru

THE report embodied in this paper is based on the detailed examination of 1150 cases, and covers a period of 9 years. The early experiments were carried out in Sierra Leone during 1916 to 1918, at the instigation of Sir Ronald Ross, but the exigencies of war service made consecutive work difficult, while the influenza epidemic of September, 1918, broke the continuity of many of the experiments. The investigations were continued in the West Indies and in Venezuela.

Little that is new in our knowledge of the disease is claimed for this report, but accuracy of experiment and observation has been the aim throughout, and the correlation of symptoms with laboratory findings may prove of interest.

Three problems interested us at the outset:

1. The value of quinine in prophylaxis
2. The biological properties of the gamete
3. The causes of the changes in certain essential organs, giving rise to the syndrome called the pernicious attack

The solution to these important questions might suggest a rational form of treatment whereby localization of the disease to one or more organs could be prevented, or if present, relieved. The organisms were studied in hanging-drop and fixed preparations, and the polychrome stains employed were those of Senevet and Wright's modification of Leishman's method.

From various groups, at different times and in different localities, new arrivals in the tropics, and numbering 627, the following observations were made:

1. Red blood count
2. Hemoglobin index
3. Absolute and Differential Leucocyte count
4. Blood Pressure
5. Coagulation time of the Blood
6. Urine Examination

These were divided into three batches:

NOTE: Acknowledgment is made of the invaluable assistance of the noncommissioned officers and men of the R. A. M. C., Tower Hill, in the collecting and staining of blood films; especially are my thanks due to Sergeant Trehearne and Corporal Williams, whose enthusiasm and practical ability made possible what turned out to be a difficult and painstaking task.

- A. 209 received prophylactic quinine (5 gr.) daily
- B. 209 received an iron and arsenic tonic daily
- C. 209 received no prophylactic treatment

At the end of the first month, the number and percentage of cases admitted to hospital or clinic were:

- Group A. (31) ...14.9 per cent
- Group B. (34) ...16.2 per cent
- Group C. (39) ...18.6 per cent

Treatment during the attack consisted in the administration of quinine intravenously, 0.15 gr., or by the mouth, 0.30 gr., daily. The average duration of treatment was 10 days. On discharge, the experiment was continued.

At the end of the 2nd month:

- Group A. (42) 20 per cent Relapses or reinfections 2.2 per cent
- Group B. (32) 15.5 per cent Relapses or reinfections 6 per cent
- Group C. (60) 28.8 per cent Relapses or reinfections 9 per cent

Treatment as before was instituted, and the average duration in hospital or clinic was 9 days.

At the end of the 3rd month:

- Group A. (33) 16 per cent Relapses or reinfections 6 per cent
- Group B. (29) 14 per cent Relapses or reinfections 3.5 per cent
- Group C. (32) 15.4 per cent Relapses or reinfections 4.2 per cent

It will be noted that the relapses are given as percentages of the whole group.

Total number and percentages of cases treated or undergoing treatment at the end of 3 months:

- Group A. (106) . .51 per cent
- Group B. (95) . . .45.4 per cent
- Group C. (131) . .62.7 per cent

Total relapses or reinfections at the end of three months:

- Group A. (17) . . .8.2 per cent
- Group B. (20) . . .9.5 per cent
- Group C. (28) . . .13.2 per cent

After the 3rd month, patients from all groups received a prophylactic dose of 10 gr. of quinine daily. The admission rate for old and new cases fell to 9 per cent per month.

No. 39

NAME	DATE	B.P.	R.B.C.	L.C.	TABLE I				Fever	Spleen	Localization Signs
					H.I.	C.T.	Urine				
Gerr.K	30 5-18	124	5,280,000	6,700	0 9	5m. 10s.	N	Observations on arrival at Tower Hill			
	18 6-18	110	4,100,000	11,300	0 6	6m. 5s.	N	3 days	Enlarged	Vomiting and Diarrhea	
	20 6-18	115	3,600,000	6,200	0 5	7m. 2s.	N	Remittent	Enlarged	None	
	22 6-18	120	4,160,000	5,700	0 65	6m. 4s.	N	None	Enlarged	None	
	25 6-18	128	4,850,000	6,400	0 7	6m.	N	None	Not palpable	None	
	28 6-18	130	5,300,000	7,100	0.85	5m. 30s.	N	None	Not palpable	None	
										Rings not found after the 2nd day.	
										Treatment: Quinine intravenously (0.15 gr.) on 1st day, then 0.30 gr. daily by the mouth.	

On admission to hospital or clinic, the observations on the blood and urine were repeated, and continued every 2 days until the patient's discharge. Additional notes made included:

Localization of symptoms
Duration of pyrexia
Enlargement of spleen
Increase in large mononuclears

Table I represents a typical record sheet, while Tables II to IX, summarize the results obtained in the whole series (1150).

TABLE II
Blood Pressure

		Per cent
1. No fall	(83)	8
2. 5-10mm.	(105)	9
3. 10-15mm.	(220)	19
4. 15-20mm.	(474)	41
5. 20-25mm.	(163)	14
6. 25-30mm.	(69)	6
7. Over 30mm.	(36)	3

TABLE III
Red Blood Count
Loss

		Per cent
1. Under $\frac{1}{2}$ million	(46)	4
2. $\frac{1}{2}$ -1 million	(356)	31
3. 1-2 millions	(506)	44
4. 2-3 millions	(207)	18
5. Over 3 millions	(35)	3

TABLE IV
Leucocyte Count

		Per cent
1. Persistent Leucocytosis	(80)	7
2. Leucocytosis, followed by leucopenia	(817)	71
3. Leucopenia from outset	(253)	22
Relative and absolute increase of large mononuclears	(494)	43

TABLE V
Hemoglobin Index

		Per cent
8	(276)	24
7	(437)	38
.6	(264)	23
5	(173)	15
and under.		

TABLE VI
Urine (albumen)

		Per cent
1. No albumen	(836)	73
2. Trace	(184)	16
3. $\frac{1}{2}$ -1 per cent	(81)	7
4. 1-2 per cent	(31)	2.7
5. Persistent	(18)	1.6

TABLE VII
Duration of Pyrexia

		Per cent
1. Under 24 hours	(35)	3
2. 24-36 hours	(218)	19
3. 36-48 hours	(242)	21
4. 48-60 hours	(368)	32
5. 60-72 hours	(161)	14
6. Over 72 hours	(126)	11

TABLE VIII
Splenic Enlargement

		Per cent
1. Not palpable	(264)	23
2. Palpable during paroxysms	(828)	72
3. Persistent enlargement	(58)	5

TABLE IX
Localization Signs

1. Gastrointestinal	(125)	11 per cent
(a) Dyspepsia	(56)	
(b) Pseudo-dysentery	(49)	
(c) Cholecystitis	(11)	
(d) Choleraic	(7)	
(e) Appendicular	(2)	
2. Skin	(125)	11 per cent
(a) Herpes Labialis	(47)	
(b) Hyperpigmentation	(61)	
(c) Diffuse Erythema	(14)	
(d) Purpura	(3)	
3. Cerebral	(73)	6.3 per cent
(a) Delusions	(32)	
(b) Polyneuritis	(13)	
(c) Comatose	(11)	
(d) Meningitic	(8)	
(e) Mental	(4)	
(f) Cerebellar	(3)	
(g) Hemiplegic	(2)	
4. Urogenital	(42)	3.6 per cent
(a) Malarial Hemoglobinuria	(22)	
(b) Nephritis	(18)	
(c) Orchitis	(2)	
5. Circulatory	(29)	2.5 per cent
(a) Tachycardia	(19)	
(b) Arrhythmia	(8)	
(c) Anginal	(2)	

Examination of these record cards brings out the following points:

1. Anemia is marked and progressive during the first week of the attack, but as a rule recovery in new cases is prompt.
2. The blood pressure, at some period of the paroxysm, is lowered almost invariably. There is a marked relationship between a low blood pressure and localization of symptoms.
3. After a preliminary leucocytosis, leucopenia is the rule, and in the majority of the readmissions there is a relative and absolute increase in the large mononuclears.
4. The coagulation time of the blood is sometimes increased, sometimes unaffected, and more rarely decreased.
5. In the majority of the cases rigors are not marked.
6. The temperature charts are very irregular in first attacks, but become more frankly intermittent in the relapses.
7. The rate of hemolysis is less marked in the relapse, although the anemia is as a rule more profound.
8. Where quinine prophylaxis (gr. 5) daily has been given, the clinical symptoms of an attack are often more intense, and the immediate reaction to quinine less effective than when no prophylaxis is employed. This is more noticeable in first attacks.
9. The addition of iron and arsenic to the prophylactic quinine, although it did not materially decrease the number of admissions, diminished the amount of anemia associated with the attack.
10. In areas where malaria infected mosquitoes are numerous, quinine in 5 gr. doses is insufficient to prevent an attack. By doubling the daily dose the incidence is much reduced (40 per cent less in one locality).
11. Quinine treatment by the mouth, provided there is no vomiting, seems to be as efficacious as by any other route.
12. The more marked the anemia the greater the tendency to localization of symptoms.

In order to determine whether the prophylactic doses of quinine or the much larger therapeutic doses would of themselves produce anemia, 10 volunteers, none of whom had suffered from or were exposed to malaria, were given 30 gr. of quinine a day for 3 weeks. In no case did this dose have any hemolytic effect.

The increased coagulation time of the blood suggested that a calcium salt might be a useful adjunct in treatment, but experiments carried out after the administration of large doses of calcium chloride produced no effect whatever either on the coagulation time or on the general condition of the patient.

The lowered blood pressure, combined with the post-mortem findings in the viscera of malarial cases, in which small infarcts were frequently present, suggested that good results might follow by raising temporarily the blood pressure with a view to dilating the capillary vessels, and so preventing or reducing this blocking and concentration of toxins. The intravenous injection of large quantities of isotonic

saline in some of the more severe pernicious cases seemed to be efficacious, but better results were obtained by infusing a saline solution containing an osmotically active colloid, such as gum acacia. To these solutions quinine in varying doses was added (10-20 gr.). In a few of the cases the temperature dropped in the course of a few hours and did not rise again; in others, localization symptoms disappeared rapidly after the injection.

Turning now to the biological properties of the gamete, Schaudin's speculation that the relapse in malaria was due to parthenogenesis, the macrogametes being converted into schizonts and then starting a new asexual cycle, seemed plausible. But the evidence given below tends to support the view of Sir Ronald Ross that the parasites are capable of survival for long periods in the viscera, and that a partial immunity exists which, under certain conditions such as fatigue, excesses etc., is broken down.

As late as 1918, the authors of *Malaria in Macedonia* summed up their conception of the rôle of the gamete as follows:

The hematozoan also gives rise to certain elements whose rôle is all important, known as gametes (sexual form). These elements are formed at the expense of the schizonts and ameboid bodies, which instead of dividing into rosette bodies, become transformed into a body which is either rounded (in *Plasmodium vivax* and *Plasmodium malariae*) or falciform (in *Plasmodium Falciparum*), and is soon set free in the circulation. This body, which is the gamete, possesses two extremely important biological properties. In the first place, it is responsible for the chronicity of malaria in the human organism, and secondly, it is the cause of the persistence of malarial epidemics throughout the globe. The gamete is extremely resistant to quinine, while the vegetative forms (schizonts, ameboid bodies and rosette bodies) are destroyed by the drug, the gametes may persist in the organism for months or years. Now under certain conditions, when the organic resistance gives way, under the influence of fatigue or meteorological circumstances, the gametes, which had hitherto remained quiescent, like parasitic cysts, begin to divide, and by multiplication of their nuclei give rise to rosette bodies, the rupture of which sets free the merozoites. The latter at once attack the red corpuscles, increase in size and number and the ordinary cycle of schizogony is reproduced. This special process of segmentation is called parthenogenesis of the gametes. This is the ordinary process in relapses in malaria. It can easily be understood that so long as these special elements persist in the organism, the patient is exposed to a relapse, and it is in this sense that it may be said that the gamete, and the gamete only, keeps up the chronicity of the disease.

The evidence for these conclusions seems to me unsatisfactory. My researches into this problem resulted as follows:

1. Despite Karrawy's observation that he found parthenogenesis to occur in *Plasmodium vivax* at the height of the paroxysm, most careful examination of thousands of films and hanging-drop preparations in a large number of malarial cases, has failed in every instance to show anything suggestive of retrogressive schizogony. When gametes existed in the peripheral circulation, a double infection

of a corpuscle with a schizont and a gametocyte was not infrequently observed.

2. Post-mortem examination of smears from the viscera—spleen, liver, brain, bone-marrow—in cases known to be free from the clinical manifestations of malaria for at least 3 months before death, but all of whom were chronic malaria subjects, showed the capillaries filled with blood containing parasites and leucocytes with pigment; the red cells of the splenic pulp contained schizonts and crescents.

3. Provocative attacks of malaria were produced by the intravenous injection of adrenalin in 3 out of 6 cases whose peripheral circulation showed an excess of large mononuclears and pigmented leucocytes, but no plasmodia.

4. Splenic puncture in 10 cases with moderately enlarged spleens, in whom the clinical manifestations of malaria were absent, and crescents only could be found in peripheral blood, demonstrated the presence of sporulating forms on the films of 6.

5. A Syrian was admitted into hospital with amebic dysentery. On examination, his blood was found to be swarming with crescents, and in spite of prolonged examination of more than 100 films, no plasmodia could be discovered. There had been no clinical evidence of malaria for many months. By means of a Pravaz syringe, blood from this subject was injected directly into the basilic veins of 5 members of his family who lent themselves for the experiment, in quantities of 1 c.c., 2 c.c., 4 c.c., 6 c.c., and 8 c.c. In no case did these injections produce an attack of malaria. Sometime later, 0.5 c.c. of blood containing plasmodia from a case of sub-tertian malaria was injected into this Syrian. Within 10 days he was readmitted with a typical paroxysm, his blood swarming with plasmodia. Finally, 0.5 c.c. of his blood, containing the plasmodia, was injected into the members of his family previously inoculated with crescents. Four out of the 5 developed an attack within 2 weeks.

While the series of experiments and observations just described cannot be considered as conclusive evidence against parthenogenesis, I submit that they are sufficiently suggestive to make us hesitate before accepting Schaudin's view.

Of the fact that quinine in sufficient dosage kills the crescents in time, there can be no doubt. In one series of cases, 109 natives, whose peripheral blood showed numerous crescents but no plasmodia, were given 30 gr. of quinine a day with the following results:

Shortest time required for disappearance of crescents—5 days
Longest time for their disappearance—28 days
Average time required—17.5 days

Safe Water for Tourists

MICHIGAN began its annual roadside water survey earlier this year than usual so that tourists will be safeguarded against polluted and contaminated water and the safe water supplies will be posted before the tourist season is in full swing. Two men are sent out to collect samples of water which are sent to the state laboratory for analysis. A third man is sent out a couple of weeks later to post the supplies and safe up an analysis with a "Safe Water" sign.

Carrying Health from the Clinic to the Community

ESTHER JACOBS

Executive Secretary, Community Health Center of Philadelphia, Pa.

THE Health Extension Department of the Community Health Center of Philadelphia, in its effort to develop a health program that would reach and interest a variety of groups throughout the community, has had a very interesting experience. Our aim is to give a working knowledge of fundamental health rules for everyday use and to stress the preventive side of health work.

The Community Health Center, supported by the Federation of Jewish Charities, was organized in 1921, upon the recommendation of Michael Davis, Ph.D., after he had made a survey of the medical resources within the Federation. It is located in the same building which houses several large case work agencies of the Federation. The Community Health Center functions as a health clearing bureau for the social agencies of the Federation, whose clients come to it for complete physical and mental examinations, as well as dental care.

All examinations are made by appointment through the agency sending the clients. Before the examination the health center receives from the agency a history of the family, in addition to the social and health record of each individual to be examined. With these facts for reference the necessary laboratory tests and examinations are made. Finally, a full report of the examination, together with definite recommendations, is sent to the agency. In the Mental Hygiene Department we include psychological, psychiatric and child habit clinics.

The examining staff is composed of salaried specialists working part of the day at the Community Health Center. There are 4 physicians (2 men and 2 women), 1 psychologist, 2 psychiatrists, 1 clinical pathologist, and 2 dentists. In addition, a psychiatric social worker, a nutrition worker, an oral hygienist and adequate clinical and laboratory assistants and a clerical staff give full time. There is also a volunteer staff of clinical secretaries and clerical workers.

The health instruction and teaching is given first by the physician during the examination and is supplemented by the health center social worker, who also explains the recommendations made by the doctor. This is further followed up by the agency worker who is originally

responsible for referring the patient to us, and who (since our medical work is diagnostic in character) also does the refer and follow-up work through existing resources of hospitals, dispensaries, and private physicians. A food demonstration is held during clinic hours once a week. One nutritious dish is selected from the daily menu chart and prepared in the clinic, recipes in English and Yiddish distributed, and the food served to all the mothers and children present at the time.

In our health extension program we tried to cover as many sections of the city as possible and to organize groups of different types in each section. We succeeded in reaching the following groups:

A Yiddish speaking Mothers' Club, with an average attendance of 35. The importance of, planning, preparing and serving well balanced meals was discussed. Colored charts were used to illustrate menus, and recipes in English and Yiddish distributed.

Two groups of working girls in different sections of the city were interested. One, a group of 12, was organized as a weekly Supper Club. A course meal at a minimum cost of 25 cents each was prepared by the girls. Each member was responsible for some part of the evening's program. Not only was this an opportunity to teach how to prepare a well balanced meal and how to serve it, but the duties and courtesies desirable in a hostess were explained. Once a month there was, as an invited guest to dinner, a specialist in some field of health work. Thus, care of the teeth, good posture, personal hygiene were each in turn discussed. When the group disbanded for the season complete physical examinations were made, at the Community Health Center and in some instances by private physicians, and defects corrected. In one instance a psychiatric study was deemed necessary.

The second group, which met monthly, consisted of all the girls in the clubs of one of our settlements. There was an average attendance of over 100 girls from 16 to 20 years of age. Notices of the meetings were usually posted in advance as talks on "Charm and Beauty," "How to Dress," "Etiquette," etc. Through these topics health discussion was stimulated, resulting in definite questions regarding individual health problems and the advantages of health examinations, and in some instances voluntary requests for complete physical examinations.

A Health Story Hour in one of the playgrounds is held weekly. This is a mixed group of white and colored, the former usually of foreign born parents. The age group is between 6 and 10 years, and the average attendance over 60 children. It is remarkable to hear the health story repeated by the children the week after its presentation by the worker, and to realize how they have absorbed definite health rules presented in this fashion. Several mothers came voluntarily to meet the

"teacher" and tell just how the children were trying to live up to health rules.

A Health and First Aid Club is held weekly in one of the Hebrew schools. The group consists of 15 adolescent girls, 13 to 16 years old. Upon the request of the girls several sessions were devoted to sex education. One meeting was devoted to general discussion, after which the girls wrote their questions and placed them in a box for the worker to answer at the following meetings. Later the mothers of two of the girls personally thanked the worker, saying that they were grateful for the instruction that had been given since they themselves had been unable to discuss the subject with their daughters. These children not only come from the better type homes where parents are interested and coöperative, but mingle with a like group, and through their interest and activities in the club spread health thoughts and rules to a group we probably would never reach otherwise.

Recently a posture class for a limited group of children from 8 to 13 years, referred from our clinics, has been organized, and two pre-school groups in nursery schools are taken over one period a week by the health worker. Mothers of these children have formed a Mothers' Club.

During health week special programs were arranged for each group and we succeeded in inaugurating periodic health examinations for the members of the staffs of the organizations housed in the building, except where individuals were already under the care of private physicians.

In the past 6 months we have reached an average of over 300 individuals outside of the health center each month through the various clubs, classes and lectures. These are in addition to those coming to our medical, mental and dental clinics for original and reëxaminations. We have examined 4,895 in our Medical Department, 1,404 in our Mental Department, and have given dental care to 6,182 during the past year. It is not, of course, possible to estimate the number reached indirectly through the extension work. Requests for a continuation of the clubs and classes have been made and we are encouraged by the thought that health information has been spread and taught through the various activities and are considered of sufficient value to be continued.

Incidence of Tuberculous Infection in Children from Rural Districts*

RUTH E. VORIES, M. D.

The Mayo Foundation, Rochester, Minn.

UNTIL 1924 when Slater reported the results of the von Pirquet tuberculin test on children in a rural community in Minnesota, all of the statistics on the percentage of positive tuberculin reactions in children were compiled from data from clinics in the large cities of this country and Europe. Slater reported only 10 per cent of positive reactions as compared with 50 to 80 per cent of positive reactions reported by continental clinics and clinics in New York City.

The question arises whether any of these figures can be accepted as representative of the percentage of children giving a positive reaction to tuberculin, because in one case the tests were given only to children living in a healthy, wealthy rural community where the incidence of tuberculosis was low and the danger of infection slight, and in the others to children from the large cities, generally from the poorer, congested districts where there was obviously greater opportunity for tuberculous infection to occur.

At the Mayo Clinic we have an opportunity of examining children from many different sections of the country and from all types of environment. Since a tuberculin test is done as a routine in the case of every child who registers in the Section on Pediatrics, it might be valuable to collect data on the results of tuberculin tests from a larger group, geographically speaking, than is covered by any of the data available at the present time.

This study was made to determine the results of tuberculin tests on children coming from rural and semi-rural districts. The results reported were collected from a study of the histories of 1000 children between the ages of 6 months and 15 years, living in communities with a population of less than 25,000 and coming from 35 states, Porto Rico, Mexico, and Canada. All cases in which there was any evidence of active tubercular lesions were excluded.

In the 1000 cases there were 169 (16.9 per cent) in which the tuberculin reaction was positive: There were 532 boys, and of these 15 per cent gave positive reactions; 468 were girls and of these 19 per

*Presented at a meeting of the Northwest Pediatric Society, Rochester, Minn., July 16, 1927.

cent gave positive reactions. Table I shows the results of the 1000 tests with the number and percentage of positive reactions according to age groups. A study of this table will show that there was a slightly higher percentage of positive reactions among the girls. Except for 3 girls aged 1 year, no positive reactions were recorded for children less than 2 years of age. While there was no striking increase in the percentage of positive reactions with the increase in age, the percentage of positive reactions among girls from 2 to 5 years of age was greater than among the boys of that age, and this balance persisted throughout the series. Slater reported practically the same observations.

TABLE I

POSITIVE REACTIONS IN THE DIFFERENT AGE GROUPS

Age, years	Boys			Girls		
	Cases examined	Positive Reaction Cases	Per Cent	Cases examined	Positive Reactions Cases	Per cent
0.5-2	21			13	3	23.0
2-5	110	11	10.0	99	13	13.1
5-10	220	36	16.3	186	32	17.2
10-15	181	33	18.2	170	41	24.1
Total	532	80	15.0	468	89	19.0

TABLE II

ANALYSIS OF CASE HISTORIES OF PATIENTS WITH POSITIVE REACTIONS

	Boys		Girls	
	Cases	Per Cent	Cases	Per Cent
Positive reactions	80	15.0	89	19.0
History of exposure	8	10.0	7	7.8
Family history of tuberculosis	16	20.0	17	19.1
No history of tuberculosis or contact	56	70.0	65	73.1
Overweight (5 per cent or more)	14	17.5	12	13.4
Underweight (5 per cent or more)	28	35.0	40	44.9
Changes in lungs in roentgenogram	15	18.7	19	21.3
Types of changes in lungs				
Calcified lymph nodes	8		13	
Bronchial thickening	5		4	
Fibrosis	1			
Infiltration	1			
Healed tuberculosis			2	

Data collected from the case histories of the patients with positive tuberculin tests are shown in Table II. It will be seen that only 8.8 per cent gave a history of known contact, whereas 19.5 per cent gave a family history of tuberculosis. Fifteen per cent of the patients were 5 per cent or more overweight and 40 per cent were underweight. The difference here is marked enough to make one attach more significance to the positive tuberculin reaction in the underweight than in the overweight child. Changes were visible in the roentgenogram of the chest in 20 per cent of the patients. The changes in the lung most

frequently found were calcified lymph nodes and bronchial thickening, neither of which necessarily indicates tuberculosis.

Family history of tuberculosis with no known tuberculous contact was shown in 124 cases of the 1000 examined. Of the 60 boys in the group of 124, 16 (26.6 per cent) gave positive reactions, and of the 64 girls, 17 (26.5 per cent) gave positive reactions. This seemed to indicate that among children with a family history of tuberculosis there is a slightly greater percentage of tuberculous infection than among children from families free from tuberculosis.

Thirty-three patients gave a history of tuberculous contact. Fifteen of these were boys, and of these 10 (66.6 per cent) gave positive reactions; 18 were girls and 9 (50 per cent) gave positive reactions. The high percentage of positive reactions occurring in children who had tuberculous contact, as compared with the percentage in children without tuberculous contact, has been commented on by all who have studied tuberculin reactions in the various groups.

In the 1000 cases there were 144 in which there was some evidence of pulmonary changes on roentgenologic examination of the chest. Seventy-five of these patients were boys and 16 (21.3 per cent) had given positive tuberculin reactions; 69 were girls and 20 (28.9 per cent) had given positive reactions. These figures suggest the possibility of a definite relation between positive roentgenologic findings and tuberculous infections in children.

In considering the accuracy of the results in this report there are several points which must not be overlooked. First, practically all the results reported are of the von Pirquet test which is applied by the burr method on the flexor surface of the forearm. The readings are taken 24 and 48 hours later. The Mantoux test, which has been shown to be much more significant for certain purposes, is used only in cases in which there is reason to suspect tuberculosis, and it is necessary to exclude a tuberculous infection as soon as possible. Second, the tests were made and read by different doctors and allowances must be made for individual variations in interpreting the results. Third, with few exceptions the results were reported after only one test. The importance of repeated tests in determining positive reactions is being emphasized more and more because there is a negative reaction following a first test in a certain percentage of noncachectic persons with known tuberculous infections, but the reaction is positive when the test is repeated.

In our records there are several cases in which the von Pirquet test was negative but because the physical examination or history suggested the possibility of a tuberculous infection the tuberculin test was later

TABLE III

COMPARISON OF POSITIVE REACTIONS IN VARIOUS SERIES

	Slater, per cent	Green and Forbes, per cent	Mayo Clinic, per cent
Entire group	10.0	45.2	17.0
With contact	81.0	64.0	58.8
Without contact	5.3	19.4	6.0

repeated by the Mantoux method. Sometimes a positive reaction was not obtained until a second Mantoux test was given or the amount of tuberculin was increased.

In conclusion, attention is drawn to the fact that our results are comparable to those of Slater, and of Green and Forbes who reported the results of tuberculin reactions in children in rural and semi-rural districts near Denver, the results being classified according to whether the children had or had not been in contact with tuberculosis (Table III).

NEW UNION STATION, CHICAGO

The Importance of Proper Training for Sanitary Inspectors*

ERNEST W. J. HAGUE

Chief Health Inspector, City of Winnipeg, Man.

THE Sanitary Inspectors Association of Canada has done a great deal to improve the status of the sanitary inspector—first, by affording opportunities for the members to increase their knowledge and usefulness, and second, by helping to remove that notion, once so prevalent that any uneducated Tom, Dick or Harry was good enough for a sanitary inspector.

However, in Canada we still have a long way to travel before the inspector comes into his own.

We have to convince quite a number of the sanitary inspectors themselves that in these days when public health work is progressing by leaps and bounds, and when new discoveries in the conquest of disease are being made almost every year, that a person taking up public health work in any of its branches cannot be content with mere routine work, but that he or she must be of a studious nature, prepared to keep abreast of this rapid progress—to know about the new discoveries, and to apply them in his daily work. We also need to convince quite a number of inspectors of the advantage of belonging to an association such as this, which exists for the benefit of sanitary inspectors and other health workers.

Next, we want the support of the health officers. We want to show them how much better work they will be able to accomplish when all public health workers are properly educated and trained.

We also need to convince governmental and municipal authorities who employ sanitary inspectors and other health workers that they can get better value for their money by insisting on proper qualifications for such workers.

Lastly, we seek to show the general public with whom we come in contact so much, that the sanitary inspector is not a raw man pitchforked into a public position by means of some "pull," but a man specially educated and trained for his particular work.

What is a sanitary inspector, and what are his duties? In the first place we note a great diversity in these duties. H. P. Boulnois, late

*The following is a paper presented at the Annual Convention of The Sanitary Inspectors Association of Canada, held at Winnipeg, Man., in 1916.

Engineering Inspector of the Local Government Board, England, once had this to say on the matter:

In order to carry out the multifarious duties of his office, an inspector should be partially educated in the following trades and professions: That of a *plumber*, in order to detect bad work, and to be able to specify in his notices how the bad work is to be rectified. That of a *builder*, in order to detect improper sanitary construction, and state how it must be remedied. This is of greater importance where, as in some towns, the sanitary inspector has to carry out the duties of a building inspector, and watch the erection of new houses which are being erected under the by-laws regulating new buildings. That of a *butcher*, in order to detect and intercept bad meat. That of a *veterinary surgeon*, in order to observe animals that may be suffering under the Contagious Diseases (Animals) Act, and also in connection with his visits to slaughter-houses. That of a *lawyer*, in order that he may be well cognizant with all the Acts and Regulations under which he carries out his duties, and to enable him to form a judicial opinion upon all statements and facts. That of an *architect*, in order that he may understand plans, and if necessary, make sketches of anything that comes under his notice in connection with his duties. That of a *clergyman*, in order that he may preach the good tidings of sanitation, and may by his precept and example further the good work he is engaged upon, and also that he may be able to patiently bear the abuse which he may sometimes receive for what is called his "prying interference." Lastly, he must try and educate himself in *common sense*, that most valuable commodity, without which book learning availeth not much.

A few extracts from Taylor's *Sanitary Inspector's Handbook* may not be out of place here:

To carry out his duties efficiently, the sanitary inspector must exercise great forbearance, tact and good temper; sometimes technical objections will be raised to his proceedings, vexatious delay and evasions will often occur in the fulfilment of his notices, nuisances which the officer is anxious to suppress may elude his authority; when he would force one person to refrain from tainting the atmosphere with the result of an offensive trade, where he would oblige another to see that his tenants were better housed than cattle, he will often be reminded of the rights of property and of an Englishman's inviolable claim to do as he will with his own. With private affairs he should interfere only when they become of public import, and with private liberty only when it becomes a public encroachment.

Thus neither the personality nor the office should be magnified. To do this is to court the contempt of ordinary men and women. Officialdom is the curse of any administrative body. Therefore the man who goes about his duties in a way that compels respect, and whose tactful demeanour impresses others that the thing he is asking for cannot be denied, is the one who will win his way to the front. Owners and occupiers are but human, and they like to feel that they are receiving the attention of a friend, although an official.

And again speaking of qualifications:

Sanitary authorities do not and have not always sought to appoint the person best fitted for the post of inspector. They have too frequently appointed the man who could command the greatest influence with its members without the slightest regard to his qualifications. The important duties which sanitary inspectors are now called upon to discharge, and the large discretionary power that must be vested in them, demands that only qualified persons should receive these appoint-

all certificates granted. I know that this offer has been made in Manitoba. It should be noted that the certificate of the Joint Examination Board in England will be harder to get than the old one, mainly because a much higher standard of preliminary education is required of the candidates. Some secondary education is also insisted upon. Candidates in addition to this must have attended a 6 months' course and also have received practical training in a public health department of lectures and demonstrations at an institute recognized by the board, for at least 300 working hours during a period of 1 year. The Ministry of Health is making arrangements with municipalities for the giving of this training.

This is a very brief description of the new regulations, but it indicates a movement toward a much higher standard for sanitary inspectors in England and Wales. New Zealand and Australia are moving in the same direction. What about Canada? Outside of the Province of Saskatchewan and the City of Winnipeg, I know of no place where the obtaining of a certificate is required as a precedent to appointment. Surely now that Canada ranks as a nation, we should not be satisfied with anything but the best. One of the main objects of our association is to promote the knowledge of sanitary science. How can we do this if we ourselves have not that knowledge?

One of the difficulties in this new country has been the lack of courses of lectures for sanitary inspectors, and of opportunity for gaining practical knowledge. The universities should provide the necessary classes. Practical training might be obtained by students in acting as voluntary part-time helpers in health departments. All, however, might not be able to get to the university centers, but in the larger cities private classes under a good tutor can accomplish much. This method has been very successful in Winnipeg. But even isolated students should not despair, for many students have prepared themselves for examination by private study. A course of lectures or a class held for students studying for examination, should be quite different from a short course of lectures intended for inspectors holding official positions. In the first instance the student has to begin with the elements of the sciences, such as arithmetic, mensuration, geometry, physics, chemistry, etc., before commencing to consider the application of these to sanitation. The period of study must cover a fairly long interval. The short courses on the other hand are intended for practical men already knowing a good deal about the subjects dealt with, but anxious to acquire the latest and best information. Examples of the latter may be found in the lectures and demonstrations provided in England by the Royal Sanitary Institute, or by the courses in dairy inspection now

being given in England as arranged for by the Ministry of Health.

Our association stands for the enactment of legislation in all the provinces which will require, in the case of future appointments to the position of sanitary inspector, a qualifying certificate from some recognized national examining body.

We do not advocate this because we believe that a man who has succeeded in obtaining a diploma knows all about public health work. It takes years of practical experience to become really well qualified; but we do claim that men and women who have taken the trouble to obtain a certificate are likely to become valuable workers more quickly. Some health officers say that they prefer to train their own men, and no doubt a few health officers do good work along this line. Most of them, however, are too busy to attempt it. If I were a health officer and had to break in new men and train them to be useful, I should at least like them to know something of the sciences underlying the work, something of the triumphs of public health work in the past, and have an idea of the best methods now pursued in this and other countries.

I am rather amazed at the indifference of many health officers as to the qualifications of the men who are given them to work with. One would think, in view of the fact that considerable importance is today attached to the proper training of health officers, bacteriologists, public health nurses, and other health workers, that both the Canadian and American Public Health Associations would have adopted before now, some scheme to help the sanitary inspector also.

It should be clearly understood that what has been said about certificates being compulsory does not apply to sanitary inspectors already holding positions. By dint of study and hard practical experience many of these are the equal of any certificated men. We need them all within the fold of our association.

We want to raise the status of the whole profession, and the best, and in fact the only way to do this, is by means of education. We claim to be technical experts, and that we should receive remuneration on the scale of technical experts. This can only be accomplished by actually becoming technical experts and then by convincing health officers and employing authorities that we are entitled to better consideration as such. Get the technical ability and the remuneration will follow naturally. This education should be continuous. Systematic reading on subjects pertaining to public health work is an absolute necessity. There are available a large number of textbooks, reports and journals. We should have a conception of what is being done all over the world in public health work.

I said at the beginning that our first task was to convince the sani-

tary inspector himself of the importance of education and proper training, and of a continuous process throughout life of absorbing knowledge pertaining to his chosen profession and trust that what I have said may convince some of this necessity.

The next most important work of our association is to convince health officers of this necessity for trained men. Sanitary inspectors have not the slightest desire to usurp in any way the functions or prerogatives of health officers. On the contrary, our sole desire is to make ourselves as efficient as possible that we may become what we should be—the right hand of the health officer. In England the position of a sanitary inspector is different. There he is a statutory officer and may exercise certain powers, independently of the health officer. In Canada, however, the health officer is in supreme control, and personally I think ours is the better system, and tends to accomplish better work. What could a health officer accomplish without his assistants? Imagine a well qualified man—a D.P.H. if you like—being appointed as health officer of a large city and given no assistants. He would naturally say: "Where are my sanitary inspectors, my food and dairy inspectors, my communicable disease inspectors and nurses, my bacteriologist? I want these and I want good men and women, properly trained, if you expect me to do anything of value for the community."

And so, we appeal to the health officers for a more active support. We suggest that health officers might help along the following lines:

1. Demand that the public health workers appointed to assist them shall be properly qualified.
2. Assist in procuring such legislation in each province of Canada as will prevent the appointment in future of unqualified persons.
3. Assist in the training of the men and women composing their staffs, both by their own personal instruction, and by helping to secure the provision of lecture courses and demonstrations for sanitary inspectors.
4. In provinces where the Royal Sanitary Institute has at present no examining board, to assist in having such a board appointed. If a Canadian certificate is desired, arrange with the government of each province for a joint examination board composed of representatives appointed by the government, the Royal Sanitary Institute, and the Sanitary Inspectors' Association. In each province the examinations might be almost uniform, and the certificate issued to successful candidates might bear the name of the government of that province. This certificate should, however, be recognized officially throughout Canada as the certificate required by law for all future appointments after a given date. It might even be possible to arrange with the Dominion Government and the Royal Sanitary Institute for the establishment of an examination board for all Canada. Such a board would comprise five or more members for each province.
5. Give this association and the branches thereof their personal sympathy and support.

If we can induce health officers to do this, good results will follow.

If our chiefs, the health officers of Canada, see that we are in earnest in this matter, they can scarcely refuse to help in a matter which so closely touches them and their work.

The above remarks apply equally to mayors, aldermen, and those responsible for appointments to positions in health departments. This association is not a trades union, and does not exist *per se* for the purpose of raising salaries. But, if you are going to appoint men and women to help to carry on this great work, why not make sure that they know their job? If well qualified, they will be cheaper in the end.

The sanitary inspector and the public health nurse come into daily contact with more citizens than any other health officials. In the course of their daily work they are called upon to discuss health topics and measures. They should be well qualified to do this convincingly, and also be able to correct some of the inaccurate notions found among the public and obtain their coöperation.

Just a word here, lest anything I have said should convey the impression that there are no certificated inspectors in Canada—there are many, and most of them belong to our association. Six candidates obtained certificates in Manitoba in April, this year. If certificates become obligatory there will be no lack of applicants.

Dental Service for School Children

FREE dental treatment for children whose parents are unable to pay has recently been started in Habana, Cuba, and nearby towns by the Department of Public Health. Dental inspection of all public school children has been practiced for some time. During December more than 5,000 children had their teeth examined; 3,200 of them needed treatment; 915 were treated free.

Conveyances have just been provided in order to permit better service in the schools on the outskirts of the city.—*Diario de la Marina*, Habana, Jan. 10, 1928.

What Is Public Health?

A Symposium

THE definition of public health is not a mere matter of wording. It is one of fundamental concept. The answer is not quite so simple as the constant use of the term would lead one to expect. There are several reasons for this. Two words are used in the term. The term is comparatively a recent one and not nearly so old as law, religion, medicine (and are these easy of definition?). There are so many activities embraced in public health that workers in these different fields may be expected to view the whole from their particular angle.

Recently a few members of the public health profession were asked to submit their definitions of public health in writing. Some forthwith began to make excuses. One state health commissioner admitted:

Your letter asking for my definition of public health has driven me nearly crazy. I am sorry that I really can't do it now and anyway, nobody would care what my definition was. When the hot weather comes and I am thinking more freely, perhaps I can do something.

Others, while admitting the difficulties of such definitions, stood up under the strain. A few protested, but sent in their requested contribution. One contributor wrote:

Definitions are dangerous things. I remember one on health, by a distinguished authority. It ran somewhat thus: "Health is a condition of the body which only exists when all the organs of the body are in a healthful state."

Still another protested:

I am consistently opposed to definitions of any kind except of single words, since in definitions, we limit our field with meaningless generalities.

The foregoing extracts from the letters received will indicate that the task of defining public health is not an easy one. Yet it is important for us to define our field and to have a clear fundamental concept of it. The definitions which follow, though they show considerable differences, help toward these ends.

E. L. Bishop, M.D., Commissioner, State of Tennessee Department of Public Health:

Public health practice is the organized effort of society to eliminate disease, elevate the standard of health and well-being and increase the span of life. Its scope of activity deals, not only with the causes and conditions of disease, but with the causes and conditions of health as well. In dealing with the causes and conditions of disease, activity must be essentially preventive in character, whereas in dealing with the causes and conditions of health activity must be productive of such causes and conditions.

H. W. Hill, M.D., University of British Columbia, Department of Nursing and Health, offers a self-contained statement which includes the implication that public health applies not only to individuals but to masses:

Public health is the science and art of conscious physical (including mental) adjustment between man and his surroundings in the universe. It is the science and art of human physical life within groups of people.

The Canadian Public Health Journal, in a publication soon to be issued, after the subsidiary terms hygiene and sanitation are first defined, the following definition will be used:

Public health is hygiene and sanitation applied to individuals, *en masse*, with special attention to the inter-relations of the individuals: it is the inclusive term under which may be placed all the science and art of our present civilization which bears in any way on the achievement of better adjustment between man and his environment.

H. S. Cumming, Surgeon General, U. S. Public Health Service:

Public health is a specialty of medicine whose function is to make applicable and to apply medical knowledge for the preservation and improvement of the health of populations.

Matthias Nicoll, Jr., M.D., Commissioner, State of New York Department of Health:

The field of public health comprises two chief functions: First, the administration and enforcement by health officials of the Public Health Law; and second, the promotion by coöperation between official and non-official health agencies—including the medical profession—of well conceived and practical measures directed toward the preservation of life and improvement of physical and mental health.

Curative medicine, in the commonly accepted meaning of the term, should not be included among official public health activities, except in emergencies and when, in the absence of proper medical care, there arises a menace to the health of the community.

George W. Fuller, Fuller and McClintock, Engineers, New York, N. Y.:

Public health is the health of the community considered as a whole, and its maintenance relates particularly to protection and promotion of the health of individuals and community groups through the systematic application of medical, biological, chemical and engineering sciences in establishing suitably favorable conditions for well-being and health.

Professor Ira V. Hiscock, Yale University, School of Medicine, Department of Public Health:

Public health is that which develops and conserves health and lengthens life by means of community activities organized to secure environmental sanitation, communicable disease control, early discovery and preventive treatment of disease, and the education of the public in the principles of healthful living.

J. L. Pomeroy, M.D., Health Officer, County of Los Angeles, Calif.:

Modern public health is the advancement of community health by the creation of an equal opportunity for every citizen to enjoy the fullest possible physical, mental and social development through the application of scientific knowledge in its

broadest sense to the environment of and to man himself, not as act of charity, but as a fulfilment of the obligations of democracy under our constitution.

W. S. Leathers, M.D., Vanderbilt University, School of Medicine, Department of Preventive Medicine, suggests that three points of view may be considered: (1) from the standpoint of the health of the public, (2) with reference to practice, and (3) as a science. He offers a definition of the term from the viewpoint of science and as a phase of medical service:

Public health is the application of the principles of preventive medicine to the control of disease and to the maintenance of individual and community health.

Sophie C. Nelson, R.N., Superintendent of Nurses, Visiting Nurse Service, John Hancock Mutual Life Insurance Company, Boston, Mass.

If the definition of public is "of or pertaining to the people" or "pertinent to or affecting a nation, state or community at large," and health is "a normal condition of body and mind," public health is the result of efforts for attaining and maintaining the maximum health of every individual through the joint endeavor of all.

S. J. Crumbine, M.D., General Director, American Child Health Association:

A recent writer has defined hygiene as follows: "Hygiene aims to make growth more perfect, life more vigorous, decay less rapid, death more remote."

Public health embraces a knowledge of those sciences, the application of which to human conditions and environment is designed to favorably influence the health status of the people of a community as a whole, and which, with applied personal hygiene, will provide the optimum conditions under which the aims of hygiene may be more certain of realization.

E. R. Hayhurst, M.D., Ohio State University, College of Medicine, Department of Public Health:

Public health is the philosophy, art and science of hygiene in its broadest sense as applied to groups of human beings, usually considered as within national, state, or other civic boundaries, and fostered by voluntary as well as official agencies. Hygiene implies the engendering of well-being, maintaining of the same, increasing its possibilities, preventing disease, and providing for the eugenic propagation of the race.

C.-E. A. Winslow, Dr. P.H., Yale University, School of Medicine, Department of Public Health:

Public health is the science and the art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing service for the early diagnosis and preventive treatment of disease, and the development of the social machinery which will insure to every individual in the community a standard of living adequate for the maintenance of health.

SUMMARY

In general it is to be noted that the definitions deal with practices rather than principles. With one possible exception, the definitions do

not include any very direct reference to heredity as a factor in public health.

The similarities are greater than the differences in the definitions which have been listed. The order of the ideas, and the words used as sentence structure bridges between them vary as would be expected. But there is a remarkable uniformity in the ideas presented. What are some of the essential concepts which recur in these definitions?—

That public health deals with the causes and conditions of health as well as of disease.

That the object of public health is elevation of the standard of well-being, increase of the span of life, disease prevention, adjustment of man to his environment.

That these objects are achieved in the individual and in social groups.

That the factors involved in terms of knowledge are related to biology, chemistry, education, medicine, engineering, nursing and law.

That public health is made possible by individual and collective effort through official and voluntary agencies.

That public health is both a science and an art.

TENURE OF OFFICE IN THE HEALTH DEPARTMENT

IN his discussion in *Health Problems in Organized Society*,¹ Sir Arthur Newsholme makes the following statement:

Public health work must be made practicable as a career; and to this end reasonable security of tenure of office must be given to competent officers, and their remuneration must compare not unfavourably with the earnings of physicians in private practice. Happily both these objects are now approximately secured in England.

That they are objects still to be attained in this country every American sanitarian recognizes. Examples of the disturbance of the continuity of state and municipal health work by political interference are recent enough to keep the problem clearly in the foreground. The possibility of the recurrence of such incidents, disturbing alike to the state or city involved, and to general public health progress, is revealed in a recent survey made by the American Public Health Association's Committee on Permanency of Tenure.²

The insecurity of tenure of office among the health officers of 156 cities is revealed by the answers to five questions devised to throw light on the present American situation. Only 1 out of 5 health officers is appointed by a board of health. The health officer's appointment is regulated by civil service in less than one-fifth of these cities. Only 7 out of 10 cities require that the health officer shall devote his time exclusively to the duties of his position. About one-fourth of the cities appoint the health officer for a term of 2 years or less; less than half (46 per cent) make the term of office "indefinite, or at the pleasure of the appointing body."

Other municipal officials escape these hazards of the health officer's position. Almost all superintendents of schools in these cities are appropriately appointed by boards of education. They are on full-time service, as are the majority of city engineers and fire chiefs. The number of fire chiefs enjoying the privilege of an indefinite term of

office appreciably exceeds the number of health officers appointed on this basis. The average term served by the predecessors of fire chiefs in these cities was, consequently, twice as long as that of the predecessors of the health officers.

The second problem, that of adequate remuneration for the health officer, is equally far from solution. The average annual salary of the health officers in these cities was \$4,420, yet the majority required that the health officer possess a medical degree. On the other hand, superintendents of schools, required in only 11 per cent of the cities to have a college degree, received an average annual salary approximately \$3,000 higher. The implication is, of course, not that the latter salary is too high, but that the former is too low. The desideratum is remuneration commensurate with the professional requirements of the position, and this has certainly not been attained in the case of health officers.

In the present survey, only 3 cities made the degree of Doctor of Public Health compulsory for their health officers. Only 29 of the 1281 state, county and city health officers listed by the U. S. Public Health Service up to January 1, 1928, held the degree of Doctor of Public Health, or the Certificate in Public Health.

If the profession of health administrator, in city, county, or state, is made financially safe, more young men and women will seek special public health training in the universities, and the supply will satisfy the demand. That this aspect of the problem also demands attention is indicated by the report of the American Public Health Association's Committee on Training and Personnel,² which states that only 104 public health degrees were granted in 1926. Ferrell³ has estimated that adequate health service for the entire population of the United States requires the training of 570 health officers annually. The inadequacy of the present output of potential health officers may be readily seen.

Like most of the problems of organized society, the dual health problem presented by the existing insecurity of tenure of office and low remuneration of health officers can be solved best by education. Intelligent citizens, convinced of the vital importance of health work to the community, will guard the position of health officer with the assurance of opportunity for uninterrupted efficient service with adequate compensation. But the educational method is necessarily a slow one. Meanwhile, there is at hand a specific means for hastening the education of the present generation of voters—the use of the *Appraisal Form*. A constantly increasing number of health officers is making this form the basis for a tangible record of progress, which is intelligible to the taxpayer. State-wide surveys in Michigan, Wisconsin, Illinois, and

individual cities—Detroit, Boston, East Orange, Racine—have made notable use of it.

The extension of the use of the *Appraisal Form* will make an immediate contribution to the general and individual solution of the health officer's dilemma.

RHEUMATISM AND HEART DISEASE

THE importance of rheumatism as a disease of childhood with consequent damage to the heart, has often been pointed out. Apart from the ordinary acute cold, there is scarcely an ailment with which the average practitioner comes more frequently into contact. Possibly "familiarity breeds contempt." It is reasonably sure that the average physician does not consider the usual case of rheumatism as being serious. Parents and those generally who have to deal with children pay little attention to the ordinary rheumatic pains, and it is well known that the so-called "growing pains" are seldom given serious consideration, despite the warnings which have been issued.

Two years ago Drs. Barker and Cole¹ devoted to this subject a volume which deserved wide circulation, pointing out, as it did, that between 80 and 95 per cent of heart trouble in young people had its origin in some form of rheumatism. They quoted studies which indicated that there were at least 167,000 cases of rheumatic fever in the United States in 1916, of which 40 per cent almost certainly developed chronic and serious heart disease. During the World War 88,000 cases of valvular disease were found in 2,500,000 men examined in the draft. A recent compilation showed that in 1917 heart disease was given as the primary cause of death in 129,000 cases, and as contributory cause in 48,000; against 191,000 and 87,000 respectively in 1925; while diseases of the arteries were assigned as the primary cause in 19,000 in 1917, and 23,000 in 1925; against 40,000 and 66,000 respectively as contributory in 1925. While the population increased 38 per cent and deaths from all causes 14 per cent, heart disease showed an increase as a primary factor of 49 per cent and as secondary factor of 81 per cent, while arterial disease gave percentages of 21 and 64 respectively.² From the financial standpoint the cost of deaths from heart disease is estimated as more than \$1,500,000,000 a year, and the cost of hospitalization as almost \$30,000,000.³

Rheumatism has been the object of numerous studies in Great Britain, where the disease seems to be, if anything, more common than in this country. Reports have been issued by the Medical Research Council and the Ministry of Health in addition to two reports by a sub-committee of the British Medical Association.⁴ The cost in money among the insured (approximately one-third of the total population) is some \$85,000,000 annually, and if the late effects are taken into consideration, the disease ranks as one of the chief causes of death.

On May 10, a Conference on Rheumatic Diseases was held at Bath, England, the ultimate outcome of which will be awaited with great interest. Sir George Newman,⁵ as President, gave a short but impressive review of the work before the conference, and a summary of the ideas which are widely held at the present time. That the disease, or diseases, which are usually classed under the name of rheumatism are not understood, and that there is good reason for differences of opinion, is demonstrated in a careful study of rheumatism among children in Cardiff.⁶

The conference was held in three sessions, which considered respectively the social aspects, causation, and treatment of the disease. Prevention seems to have been forgotten, though the paper by Dr. Reginald Miller⁷ dealt largely with environment. No physiologist, no sanitarian, and no epidemiologist, were included in those invited to address the conference. The Public Health Service and the School Medical Service were also overlooked, which is hard to understand when Sir George Newman was the president.

As far as the published reports go, little or nothing new was brought forward. The meeting was for the purpose of collecting evidence, which must now be sifted and evaluated, with the hope that it will lead to research and the adoption of practical measures.

Dr. Miller held that environmental conditions, chiefly poverty and dampness, were the great predisposing factors in children. Changes in the skin make it inefficient in its responses to cold and moisture. Deficiency in vitamin B, with intolerance of carbohydrates, are noted in pre-rheumatic children. In certain forms of chronic rheumatism the endocrine organs are at fault.

Two great obstacles—not to mention others—have barred the way to proper understanding of rheumatism: confusion in nomenclature, and failure to establish the cause of the disease. The most notable work on causation, that of Payne and Poynton, has not been generally accepted nor carried to its legitimate conclusion. The work of Small in this country is not convincing. While we may claim some advance, we must in honesty confess that the entire matter is in a state of confu-

sion, though there is a general tendency to believe that some form of streptococcus is the causative organism. He is a bold or ignorant man who would speak dogmatically on the subject.

Some facts, however, stand out clearly. Rheumatism is very common. Its effects are disastrous to life as well as health. It is especially fatal in the poorer classes who cannot take proper precautions in the way of rest nor obtain skilled treatment. It involves a heavy tax financially on every community. It is possibly to some extent contagious. Certain studies show that the contact case incidence is approximately that of infantile paralysis and cerebrospinal fever, reporting of both of which is required.

There is certainly ground for believing that the disease is preventable to a large extent. From every aspect it challenges the bacteriologist, the epidemiologist, and the health officer. It deserves more study and more careful attention than has been given in the past.

OF WHAT USE ARE OUR VOLUNTARY HEALTH AGENCIES?

DR. Oliver Wendell Holmes once said that when John and Thomas are talking together it is no wonder that confusion sometimes arises among the six of them. When asked for an explanation he said: "Why, there is the real John and John's idea of John, and Thomas's idea of John, and the real Thomas and Thomas's idea of Thomas, and John's idea of Thomas. That is six, isn't it?" There are three primary forces active in the public health movement, the health official, the unofficial health agency and the medical profession; and this, according to Dr. Holmes's computation, would make twelve possibilities for misunderstanding.

Yet it is of the most vital moment that these three active forces in the community health program should comprehend and sympathize with each other, for success involves the coöperation of all three. In the March issue of the JOURNAL the debt of the community to its health officials was discussed, and it seems time to consider what we owe to the volunteer health agencies which have played so large and so unique a part in health promotion in the United States. A little consid-

eration will indicate that there is scarcely a single stage in the public health movement in which these unofficial agencies have not played an important rôle. We prefer to call them "unofficial" rather than "voluntary" agencies because the latter term is sometimes held to imply a somewhat amateurish quality, an implication wholly unwarranted. In official and unofficial agencies alike, the paid executives are usually professional experts, quite as well qualified in one case as in the other; and in both instances the work is often directed by a voluntary unpaid board. The difference is simply that the health department is supported from the tax levy as a part of the routine machinery of government, while the unofficial agency is supported by contributions, endowments or community chest grants as an expression of the desire on the part of the citizens to further the fullest type of community life.

Let us review briefly some of our debts to the unofficial agency and see how nearly coextensive they are with the entire field of public health. The fundamental movement for environmental sanitation in the United States took its rise in the Citizens' Survey of New York City in 1865; and the latest campaign in communicable disease control for immunization by toxin-antitoxin is in large measure being conducted, in New York State and elsewhere, through the support of unofficial social agencies, following, of course, the general lines first laid down by Park and Zingher.

The anti-tuberculosis movement has from the start to the present time been dominated by the National Tuberculosis Association and other unofficial agencies, and at each important stage it is these agencies which have led, so that even today the bulk of our program for the control of this disease is carried on outside the health department. The movement for the control of infant mortality was initiated, both nationally and locally, by unofficial organizations. Even the health program for school children owes the stimulus which has transformed it in recent years to the vision of Dr. Holt and his associates in the Child Health Organization. The national programs for the control of venereal disease and for mental hygiene owe nearly all of the impetus behind them to the unofficial national organizations active in these respective fields. In industrial hygiene the individual far-sighted employer and the unofficial National Safety Council have accomplished far more than all the legislative and administrative machinery of the states. The development of public health nursing has (except on the Pacific Coast) been accomplished chiefly through unofficial agencies, and more than half of it is still conducted by such agencies. Finally, we can never express our debt to organizations such as the Metropolitan Life Insurance Company, the Milbank Fund and

the Commonwealth Fund for the health demonstrations at Framingham, Syracuse, Cattaraugus County, Fargo, Mansfield, etc., and for the stimulus and guidance they have given to our program as a whole.

The other two parties to the social contract for health promotion, the unofficial agency and the medical profession, must in the last analysis always recognize the ultimate authority of the health official. He, after all, represents the community as a whole and his word must be final. The best health officer is, however, the one who appreciates most gratefully the contribution which the unofficial agency and the medical profession can make to his program, and who uses them most generously and most intelligently for the common cause to which all three are pledged.

MAIN CHANNEL AT ROMEO, ILL., LOOKING UPSTREAM

CHICAGO'S PUBLIC WORKS SAFEGUARD ITS HEALTH

THE 57th Annual Meeting of the A. P. H. A. in Chicago, October 15 to 19, comes at a most opportune period in the development of great engineering projects of profound interest to public health workers. At no other time in the city's history has there been more activity in water supply, sewerage, garbage disposal and mosquito control than at the present. Chicago fully appreciates the truth of the slogan, "Health Is Wealth," and is investing in a most intensive way in health protection.

Before the projects for improvement in water supply and sewerage planned for this city are completed, about \$400,000,000 will have been spent in these great public works. They are a part of Chicago's vast program for municipal improvements and are responsible in no small degree for the enviable public health record attained in that city during the past decade. Certainly every engineer and probably many of health officers and other health workers in the various branches of the profession will want to visit these works. With this in mind, the local committee in charge of arrangements is making special plans to accommodate all who attend the Annual Meeting.

The Sanitary District of Chicago charged with the great responsibility for drainage and sewage disposal in the region of Chicago is now building two of the largest sewage treatment plants in the world. One, the North Side plant, using the activated sludge process will be in operation at the time of the meeting; the other, the West Side Imhoff plant, will be nearly completed in its first unit and at a most interesting structural stage by that time.

The city water department has under construction a new pumping station—its 12th—a tunnel 200 feet under Lake Michigan, and a new intake crib structure said to be the largest ever built. During the last year the department placed in operation the world's largest water pumping station and the most completely equipped experimental water filtration plant ever operated. The new municipal garbage reduction plant, opened only a month ago, is considered one of the finest of its kind in America, and has already attracted wide interest among engineers.

Under a plan developed by the Gorgas Memorial Institute mosquito abatement, work in the suburbs of Chicago has been carried out this year on a very

Courtesy of Chicago Sanitary District

ENTRANCE TO NORTH SHORE CHANNEL, SHOWING PUMPING STATION AT WILMETTE

comprehensive scale through the co-operation of several official agencies. The mosquito problem in this section is a unique one and has many interesting phases.

THE CHICAGO WATER WORKS

Chicago's water is obtained from Lake Michigan through 6 intakes located from 2 to 4 miles from shore. The water is brought to the 11 pumping stations

through nearly 70 miles of tunnels under the lake and the city. The Thomas Jefferson Pumping Station, now under construction on the northwest side, will be the 12th pumping station supplying Chicago's water. It will have a capacity of 100 m.g.d. and like the more recent stations built by the city will be equipped with centrifugal pumps. The largest of Chicago's 12 pumping stations is the William Hale Thompson station, put

Courtesy of Chicago Sanitary District

39TH STREET CONDUIT EXTENSION, UNDER CONSTRUCTION IN THE BED OF BUBBLY CREEK

Courtesy of Peter Fish

WILLIAM HALE THOMPSON PUMPING STATION

into operation for the first time last spring and having a capacity of over 300 m.g.d. The total pumpage capacity of all stations, including the Thomas Jefferson, is over 1,500 m.g.d. The average daily pumpage is about 900 m.g.d. Chicago pumps more water than any city in the world.

A new tunnel system known as the Chicago Avenue Tunnel is now under construction, approximately four miles

of the tunnel having been dug already through solid rock, 200 feet below the lake. To serve this tunnel intake, a crib structure 90 feet in diameter has been built near the Municipal Pier. It will be launched, towed out to its location over the intake shaft in the lake, and sunk in its final position some time this fall.

The newer tunnels are all dug through rock and are lined with concrete. They are mostly "horse shoe" in section with diameters varying from 12 to 16 feet. The older tunnels were dug through clay, and are brick lined. They are circular in section, diameters varying from 5 to 10 feet. The oldest, completed in 1867, is still in service. From the pumping stations the water is delivered to the nearly $3\frac{1}{2}$ million consumers through over 3,500 miles of cast iron pipe. The per capita consumption of water in Chicago is excessive, averaging about 300 gallons per day. This is considered to be due largely to wastage by small consumers. Chicago meters only 35 per cent of its water, and this is to the large consumers such as industries and large apartment buildings.

The only treatment given the raw lake water for purification is chlorination at the pumping stations. The system for supervision and control over the

chlorination of Chicago's water supply is exceptionally well organized. About 3500 pounds of chlorine are applied to the water daily. While this method provides a safe water, it does not give a first class supply. During and following storms on the lake the water becomes turbid for days and even weeks at a time, especially during the winter and spring months. In the summer and fall the water due to plankton forms in the lake water. The water in the vicinity of the southern cribs is exposed from time to time to pollution from the cities and industrial plants in the southern end of Lake Michigan in the so-called Calumet district of southern Illinois and northern Indiana.

Realizing that a clean, sparkling and safe water supply at all times is not only a necessity but a public asset, Chicago is preparing for filtration of its water. The first step taken was the construction of an experimental plant. This station, which was completed this spring at a cost of about \$150,000, is now operating and a most elaborate series of experiments on the treatment and filtration of Lake Michigan water is being conducted. The plant is in charge of experts and it

is confidently believed by those who have seen the station and reviewed its program that findings of far reaching importance to water purification will result from the experimental work conducted there. The plant consists of two large size rapid sand filters with ten smaller filter units and various types of

CALUMET SEWAGE TREATMENT WORKS, IN OPERATION SINCE 1922

mixing and settling basins for pre-treatment of the water. It is a station which should be visited by every public health engineer and sanitarian.

The Chicago water works system to date has cost over \$110,000,000 and when filtration plants to treat the entire supply are completed this investment will probably be over \$150,000,000.

Under the present permit from the Secretary of War, a flow of 8,500 cubic feet per second is allowed from Lake Michigan in addition to the water supply.

The original works of the District consisted of the main channel running from the South Branch of the Chicago River at Robey Street to Lockport on the Des Plaines River. This was opened for

NORTH SIDE TREATMENT PLANT. THIS PROJECT WHEN PLACED IN OPERATION WILL HANDLE THE SEWAGE FROM AN AREA OF 78 SQUARE MILES, AND A POPULATION OF 800,000.

THE SANITARY DISTRICT OF CHICAGO

The Sanitary District of Chicago is a municipal corporation, including not only the City of Chicago but 59 other municipalities within its corporate area of 442.35 square miles. Originally organized in 1889 for the purpose of diverting the sewage of Chicago from Lake Michigan and diluting it with lake water in amount at least 3½ cubic feet per second, sewage treatment has been added to its functions to supplement dilution.

service in January, 1900. To this has been added the North Shore Channel, extending from Wilmette to the North Branch of the Chicago River, which it serves to flush out, and the Calumet-Sag Channel running from the Little Calumet River at Blue Island to the main channel at the Sag. Supplementing these channels as part of the dilution system are the intercepting sewers along the lake front both north and south of the Chicago River and the Calumet intercepting

system. By this construction the sewage was diverted from the shores of Cook County, bordering on Lake Michigan from the county line on the north to the Calumet River on the south.

However, with the rapid growth of the city and its industries, the load on the channel grew to such an extent that by

1909, the Sanitary District realized that treatment supplementary to dilution was required. To learn how to do this to best advantage locally, a testing station was built and operated on domestic sewage and three others, packinghouse wastes, tanneries and the corn products waste, respectively, the three most im-

portant groups of industry, aggregating a few years ago an equivalent load of 1,500,000 population as against a human population of 3,000,000. Considerable progress has been made with the handling of the corn products waste by a system of bottling up and concentration of the waste.

Recently a paint waste has been studied because of its effect on biological treatment.

The treatment program comprehends the removal of settling solids from all the sewage as soon as possible, and ultimately biological treatment.

To develop the treatment system for the Sanitary District, a number of projects were outlined, the five major ones being: the North Side, the South Side, the Southwest Side, the Calumet and the DesPlaines River. In addition a number of minor projects for the smaller isolated villages have been planned, and three have been built, one at Morton Grove, one at Glenview, and one at Northbrook.

Of the major projects, the DesPlaines River works was put in service in 1922—an activated sludge plant, serving about 55,000 people, with provision for filter pressing and drying the sludge. At this plant various experimental features have been tried—a testing station is being operated on aeration prior to trickling filters, and a sludge digestion.

The Calumet works also went into service in 1922, and is now serving about 155,000 people. This is primarily an Imhoff tank plant, but for experimental purposes two of the thirty-two tank units have been equipped as activated sludge units. A small trickling filter of 0.7 acre is also operated for experimental purposes. Tests have been made on sludge filtering and heat drying. A mechanical stripper is being developed for handling the air dried sludge from the outdoor bed. A glass covered drying bed is also operated.

Of the large works two are under con-

struction, the North Side and the West Side. The North Side works is expected to go into operation early in August, the West Side works in October.

The North Side works is an activated sludge plant, the largest in the world. It is designed to handle 330,000 people as of 1930, and an average flow of 175 million gallons daily. The plant includes the pump and blower house; the main building which houses the main meters, return pumps, excess sludge pumps, locker rooms for employes and laboratories; the grit chamber building; and the service building housing the heating boilers, machine shop, and miscellaneous shops. The sewage is pumped up 48 feet into the grit chambers, thence passing through 1-inch opening bar screens to preliminary settling tanks where the coarser solids are removed, then through the main meters to 3 batteries of aeration tanks. From the aeration tanks the sewage passes to the settling basins, the effluent going to the North Shore channel, and the sludge being returned to use over. The excess sludge is to be pumped through an 18-mile force main to the West Side works for digestion.

The West Side works is an Imhoff tank plant, the largest in the world, designed to serve 1,800,000 people as of 1940, and a flow of 400 million gallons per day. The first battery of 3 is now under construction consisting of 36 tank units. The sewage is pumped up 68 feet into the preliminary skimming tanks, about 15 per cent of the flow with the heavier solids being passed through the grit chamber. The flow then passes to the Imhoff tanks after receiving the sludge from the North Side. The effluent flows to the main channel. Sludge drying beds on a large scale will be provided, equipped for mechanical stripping and handling of the air dried sludge. A railroad is also planned to remove the sludge for dumping on some 900 acres reserved for the purpose.

LAYING THE LARGEST CAST IRON PIPE IN CHICAGO'S WATER WORKS SYSTEM

The Southwest plant has not yet been planned.

To bring the sewage to the various works a comprehensive system of intercepting sewers has been planned. Of these the Calumet and the North Side sewers have been practically completed and the West Side sewer is under construction.

Up to December 31, 1927, approximately \$126,204,310.31 has been expended on the dilution system, and in addition, \$80,378,909.17 on the treatment program, of which a large portion has been spent since 1920. Last year about \$16,371,208.02 was spent in construction of the treatment program. Ultimately some \$155,000,000 will be invested in treatment.

The program now under way has been

approved by the Chief of Engineers, U. S. Army, and the Secretary of War. To carry it out necessitated action by the Illinois State Legislature and increases in bonding and taxing power. At the present time sewage treatment is being extended on a practically unprecedented scale.

The various plants are open to visitors. Descriptive pamphlets are also available on the District works.

In addition to the sewage treatment works, a check is maintained by a fully equipped laboratory, on the water supplies taken from Lake Michigan, some 70-odd samples being analyzed daily. To follow the operation of the treatment works, branch laboratories are maintained at the Calumet and DesPlaines works.

In the study of the Illinois River conditions yearly branch laboratories are maintained at points between Summitt and Alton.

The accomplishment of the Sanitary District can best be measured by the marked reduction in typhoid fever in Chicago. Prior to the opening of the Main Channel in 1900, explosive epidemics had occurred with average yearly death rates as high as 174 per 100,000. Since the opening of the Channel the rate has steadily declined, until for the

last 2 years a rate of under 1.0 has been attained.

In addition, the shores have been cleaned up, making bathing both safe and attractive where formerly it was frequently both unpleasant and dangerous because of the presence of raw sewage.

The condition of the Chicago River has been vastly improved. Flushing also aids in keeping the North Branch and the South Branch in better shape than prior to 1900. Sewage treatment will carry the improvement much farther.

ASSOCIATION NEWS

INTERNATIONAL MEMBERS

International membership in the A. P. H. A. is increasing. Within the last month applications for membership have been received from Dr. Hou-Ki-Hou, Commissioner of Health, Shanghai, China; Dr. Ianuarie Gomoiu, Health Commissioner, Ministry of Public Health of Rumania, Bucharest, Rumania; and Dr. Aurel Voinea, Assistant Director of Public Health, Bucharest, Rumania.

A. P. H. A. membership extends into several countries of South America, into Austria, Belgium, Czechoslovakia, Spain, Denmark, France, Germany, Holland, England, Italy, Palestine, Poland, Switzerland, Portugal, China, Japan, Straits Settlements, Dutch East Indies, Syria, Borneo and Africa and Australia, Canada, Mexico and the Philippines. *The American Journal of Public Health and the Nation's Health* is posted to these countries monthly and it has subscribers also in Hungary, Jugo-Slavia, Norway, Russia, Turkey and Sweden.

COMMITTEE ON ADMINISTRATIVE PRACTICE

Professor Ira V. Hiscock of the School of Public Health, Yale University, is in Los Angeles County, Calif., making a survey of the health activities of Los Angeles County. Dr. W. F. Walker, Field Secretary of the Committee on Administrative Practice, has been on the west coast during June and July, stopping in Los Angeles to confer with Professor Hiscock relative to the appraisal of health activities being made in Los Angeles County; attending the Regional Meeting of the Association in Portland, Ore.; and making a reappraisal of health activities of Salem, Ore.

Dr. Walker gave a course of lectures, July 8-11 at Northwestern University on "Public Health Activities of a Chamber of Commerce." The syllabus of this series of lectures includes "Costs of Health Work," "Methods of Study of Local Conditions," "Fighting Disease," and "Prevention of Disease and Health Promotion." He also gave a series of lectures July 22-24 at Massachusetts Institute of Technology on the *Appraisal Form for City Health Work*.

DR. RUHLAND APPOINTED HEALTH OFFICER

George C. Ruhland, M.D., director of the health demonstration being conducted in Syracuse, N. Y., under auspices of the Milbank Memorial Fund, has been appointed full-time health officer of Syracuse, N. Y. The appointment was made by the mayor of the city upon the resignation of Dr. Herman Weiskotten, Dean of the Medical College, Syracuse University, who has been serving as health officer. The position carries a salary of \$10,000 a year. Dr. Ruhland has been serving as deputy health officer of Syracuse, receiving \$5,000 from the city and \$5,000 from the Milbank Fund. The city of Syracuse will now assume the responsibility of his salary, and Dr. Ruhland's appointment goes into effect August 1.

Dr. Ruhland went to Syracuse as director of the health demonstration in 1924. The demonstration, according to the original plans of the Milbank Memorial Fund executives, was to cover a 5-year period, which has almost expired. But it was decided to continue the demonstration indefinitely if a full-time health officer was appointed.

Dr. Ruhland is a Fellow of the Asso-

ciation and is a member of the Committee on Administrative Practice, of the Sub-committee on the Revision of the Appraisal Form for City Health Work, chairman of the Sub-committee on Record Forms, and a member of the Sub-committee on Organized Care of the Sick.

Dr. Ruhland went to Syracuse from Milwaukee where he was commissioner of health.

CORRECTION AND APOLOGY

Listing the death of Dr. Jose Amarante, Rue Lafayette 106, Rio de Janeiro,

Brazil, in the March JOURNAL was an error due to the return of mail by the Rio de Janeiro post office marked "Deceased."

STATE AND PROVINCIAL HEALTH AUTHORITIES

Matthias Nicoll, Jr., M.D., New York State Health Commissioner, was elected president of the State and Provincial Health Authorities of North America at Minneapolis, Minn., June 8-9. Dr. Nicoll is a Fellow of the A. P. H. A. and a member of the Governing Council.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Diphtheria From Carriers—A study has been made in Baltimore of the prevalence of clinical diphtheria among family contacts who have been exposed to known carriers, virulent and avirulent. Statistically it has been shown that the family contacts of carriers are exposed, within the first month after discovery, to a risk of clinical diphtheria much greater than that of the control population living in the same neighborhood. The incidence among family contacts of carriers during this period, is, however, only about one-tenth that of those in similar association with recognized clinical cases. While questioning the adequacy of their statistical evidence the authors conclude that the family contacts of carriers of virulent bacilli experience a greater risk of having clinical diphtheria than do those associated with carriers of avirulent bacilli. The brief period of increased incidence in the families of carriers is followed by a compensatory period of at least 2 months' duration in which the attack rate falls below that of the control group.—James A. Doull, Wm. R. Stokes, & G. Foard McGinnes; *The Incidence of Clinical Diphtheria Among Family Contacts Subsequent to the Discovery of Carriers*;—*J. Prev. Med.*, II:191 (May), 1928.

Schick Tests in Honduras—A study has been made of the Schick test as applied to 430 natives of Honduras in 1926 and 1927, and 40 school children of American or American-Spanish parents, and 31 negro school children. The natives, as a whole, showed a very high percentage of immunes, while the American school children exhibited a much lower percentage of immunes. In a group of 34 American children from 6 to 14 years of age inclusive, 55.8 per

cent were positive as compared with 9.6 per cent in the 196 children of the same age who were natives of Honduras. The author feels that congested living conditions have much to do with the difference in susceptibility, and that cities usually show a lower percentage of susceptibility than do rural communities.—William H. Taliaferro, *The Results of Schick Tests in Tela, Honduras*, *J. Prev. Med.*, 2:213 (May), 1928.

Scarlet Fever Immunization—Since July, 1924, in Gary, Ind., an effort has been made to immunize school children against scarlet fever. The general procedure has been to give a Dick test followed by 5 doses of toxin given at intervals of 5 to 7 days, and Dick tests given 2 weeks after the last dose. The dosage has been increased until 500, 2000, 8000, 25,000, and 80,000 have been given since September, 1927.

Fifty-three per cent of 6452 primary Dick tests have been positive. In general, younger children show a higher incidence of positive tests, and more of the American than of the foreign born children show positive reactions.

Three thousand, two hundred and fifty-five Dick re-tests have been given. Sixty-six per cent were negative, 17 per cent slightly positive, and 17 per cent positive. Of a small group that were Dick negative in May, 1927, after a full course of doses, about 70 per cent were still Dick negative in December, 1927.

Of the 433 cases of scarlet fever reported to the Gary Board of Health since July, 1924, 12 were in persons known to be Dick positive, and 6 in persons who had been pronounced Dick negative.

The authors conclude that the incidence of scarlet fever and the number of

deaths have decreased, and especially has the reduced incidence been affected among those who have had scarlet fever toxin.—Margaret G. Smythe and O. B. Nexbit, The Dick Test and Immunization Against Scarlet Fever in the Public Schools of Gary, Indiana; *J. Prev. Med.*, 2:243 (May), 1928.

Health Conditions in Bronx—The Bronx Borough of the City of New York has a large excess population between the ages of 20 and 45 years when compared with the standard United States distribution. The excess is 56,000 in this group, indicating for the men 13 per cent and for the women 19 per cent more than elsewhere.

The natural rate of increase of population in Bronx is the highest of any borough, due to a high birth rate as well as a low death rate. In 1926 the Bronx rate of natural increase was 11.90 per 1,000 annually, against 3.85 in Manhattan.

In 1926 the crude death rate was 10.52 per 1,000 and was thus 17 per cent more favorable than that of New York City in general.—G. J. Drolet; Health Conditions in the Bronx, New York City; New York Tuberculosis and Health Association, March, 1928.

Fargo Demonstration—Two parts of the final report of the Fargo Demonstration which has been carried on since 1923 through the coöperation of the Commonwealth Fund with the City of Fargo have appeared. At the beginning of the demonstration at Fargo the score, as indicated by the *Appraisal Form*, was 320 as compared with 499 as an average

score of 86 small cities in 1923. In 1927 the Fargo score had risen to 827 points.

During the year 1927 the Child Health Demonstration Committee of the Commonwealth Fund has gradually withdrawn from the activities which they had organized, leaving local personnel in the full direction of the program. The public health staff of the city paid from local funds consisted at the end of 1927, in a full-time health officer, sanitary inspector, 6 nurses, supervisor of health education, a part-time physician, a full-time dentist, and 2 clerks. The community health program for the fiscal year ending June 30, 1928, calls for the expenditure of \$1.51 per capita. The health department share of this is \$1.06, of which only \$0.38 goes to the isolation hospital. The board of education contributes \$0.41 per capita.

Dr. Walker states in his summary report that "bringing its health work up to its present high level in the space of 5 years is an achievement of which Fargo may well be proud." He further emphasizes certain definite needs as, an increase in immunization against diphtheria and smallpox; a more adequate follow-up of cases of communicable disease; a more intensive program for the early recognition and care of tuberculosis cases and contacts; a more adequate financing of dental service; an increased supervision of milk and food supplies; and provision for continued progress in community health education. —Five Years in Fargo—Part 1 and Part 2—The Commonwealth Fund Division of Publications, *Bulletins No.* 7 and 8, May, 1928.

LABORATORY

C. C. YOUNG

ANTIGENIC PROPERTIES OF BACILLUS TYPHOSUS FROM A SMALL EPIDEMIC

H. T. JONES, M.D.,

Lawrence, Kan.

and

C. M. DOWNS, PH.D.,

Department of Bacteriology, University of Kansas, Lawrence, Kan.

THE following report is made because of the interest which attaches to the occurrence of typhoid fever in a recently vaccinated individual and because a study of the infecting organisms and other organisms isolated from the same epidemic showed them to be identical with each other but different from the strain used for vaccination. The patient, O. S. aged 45, received three doses of a standard commercial typhoid vaccine on December 4, 11, and 18, 1925. This vaccine is prepared from the Rawlings strain of *B. typhosus* and strains of *B. para-typhosus* A and B, obtained from a reputable source. No appreciable reaction resulted from the vaccination. On August 10, 1926, the patient became ill. He had a temperature of 102°, diarrhea, headache and general malaise. On August 14, a blood count showed a total white count of 6,600; polymorphonuclear cells, 66 per cent; large lymphocytes, 4 per cent; small lymphocytes, 30 per cent. A stool culture was made and typhoid and paratyphoid bacilli were isolated. The typhoid organisms were found to be typical culturally but agglutinated slowly and in low dilutions only with antityphoid serum prepared from the Rawlings strain. The paratyphoid bacillus resembled *B. paratyphosus* B in its cultural reactions. The patient ran a typical typhoid course of rather mild type. The temperature was seldom above 102°. There was no delirium. On August 25, he developed phlebitis of the

popliteal vein. He was discharged from the hospital October 3, 7 weeks and 5 days from the onset of illness. Stool cultures made for release on October 8 showed typhoid bacilli but in relatively small numbers. Cultures made on October 10 and October 16, showed no typhoid bacilli. Several subsequent examinations showed that the stools continued negative. Although the typhoid bacillus was not isolated from the blood stream, the typical clinical course and the epidemiological history as given below precluded the idea that the patient was a typhoid carrier and that the organisms found in the stools were not the etiologial factor.

At about this same time 7 other cases of typhoid fever were reported and an investigation showed that they occurred on the same dairy route. These cases had been preceded by a fatal case about 2 weeks before where the patient also took milk from this dairy. The source of infection was traced by the State Board of Health to a carrier who had recently come to the dairy. The patient, O. S., took milk from this dairy and was a heavy milk drinker, so that it seemed probable that the source of his infection was the same as that of the other cases in the epidemic.

In view of the fact that the strain of typhoid isolated from O. S. was somewhat unusual in its serological reactions it seemed worth while to investigate the antigenic properties of as many

other strains as could be isolated from this same epidemic. From the 9 cases which occurred, 6 strains were isolated from the following sources: C, blood; M, blood; S, urine; O. S., stool; N, stool; C., stool. All of these cases had typical clinical cases of typhoid fever. Unfortunately, the strain isolated from the carrier could not be obtained. Accordingly a study was made of the cultural and antigenic reactions of these strains to try to ascertain if they were identical as might be expected from their common source, and also if they differed in any respect from the Rawlings strain which had been used for vaccination in the case reported. Culturally these 6 strains were typical for *B. typhosus* and differed only from the Rawlings strain in that they fermented xylose more rapidly. In order to ascertain the antigenic properties of the epidemic strains, agglutination and absorption tests were used.

Antisera were prepared from each of the 6 strains and from the Rawlings strain. Cross agglutination tests showed that the strains from the epidemic agglutinated to titer with the antiserum prepared from these strains but that they agglutinated slowly and in low dilution only with the anti-Rawlings serum. The anti-Rawlings serum agglutinated the Rawlings strain at dilutions of 1-5000 and the milk strains at from 1-500 to 1-1000 only. Absorption tests were made by absorbing each antiserum with all the milk strains and with Rawlings. These tests showed that the epidemic strains absorbed out all the agglutinins for each other and for the Rawlings strain but that when they were used to absorb anti-Rawlings serum they failed to remove the agglutinins for the Rawlings strain. Absorption of the sera prepared from the epidemic strains with the Rawlings strain weakened the titer for the milk strains but did not remove all the agglutinins for the homologous strains.

Agglutination and absorption tests with serum from O. S. after recovery showed that his serum agglutinated all the epidemic strains in dilutions of 1-500 but that it agglutinated the Rawlings strain only partially at a dilution of 1-10. The O. S. organisms used for absorption with O. S. serum removed all the agglutinins for the milk strains while absorption of O. S. serum by the other milk strains removed the agglutinins for the O. S. strain. Use of the Rawlings strain for absorption with O. S. serum removed the agglutinins for the O. S. strain and the other epidemic strains only in high dilutions of the serum. In view of the foregoing agglutination and absorption tests it seems fair to conclude that the strains of typhoid isolated from the milk-borne cases were identical with each other and probably identical with the strain isolated from the carrier at the dairy. The tests also show that the epidemic strains differed from the Rawlings strain used for vaccination in the case reported.

Although the success of antityphoid inoculation is unquestioned an inquiry into the literature reveals a number of cases of typhoid fever occurring in vaccinated individuals. We have been able to find a record of 340 cases of typhoid fever in vaccinated persons occurring since 1915, with some records of epidemics where figures are not given.³⁻¹¹ These were all well established cases of typhoid in which the individuals had been vaccinated by the subcutaneous method with one strain of typhoid or with typhoid, paratyphoid A and paratyphoid B. Many cases were reported from the French, British and German armies during the early part of the World War, but as vaccination then did not include the paratyphoid bacilli and as careful bacteriological examination was not always made, many of the so-called typhoid cases may have been paratyphoid infections. Such cases were not included in the above number.

Vaughan¹ sums up what seems to be the consensus of opinion as to the causes of typhoid fever in vaccinated individuals as follows:

1. Overwhelming infection
2. Strains of organisms against which the ordinary vaccine does not immunize
3. Failure of patient to react
4. Failure of inoculation

In our opinion two of these factors may have been operative in this case. The patient probably received a very heavy dose as he was accustomed to drink large quantities of milk and the antigenic differences which distinguished this organism from the Rawlings strain may have been sufficient so that the antibodies developed as a result of vaccination did not protect against the epidemic strain. It is not known whether the patient reacted after vaccination with the formation of antibodies against the Rawlings strain. His serum gave a partial agglutination at 1-10 with the Rawlings strain after he was convalescent. The antigenic variation from the Rawlings strain which the epidemic strains exhibited confirms the observation previously made by one of us.²² A number of other authors also have observed antigenic variations in well identified strains of *B. typhosus*. Blankenhorn,²³ Ecker,²⁴ and Myers²⁵ have observed antigenic differences in strains residing in the tissues of the host for long periods of time and in carriers. The work on these epidemic strains suggests

that we were dealing with such a strain which may have become atypical from long residence in the carrier. Olin²⁶ and others have considered cross absorption tests as evidence of the identity of strains isolated from epidemic cases arising from a common source.

SUMMARY

The case of typhoid fever reported here shows the occurrence of infection in a recently vaccinated individual. The strain recovered from the patient was found to be antigenically identical with 5 other strains from cases which received their infection from a common source, i.e., contaminated milk. These strains differed antigenically from the Rawlings strain used in the vaccine.

VITAL STATISTICS

LOUIS I. DUBLIN, PH.D.

The Homicide Record in American Cities, 1927—Deaths from homicide seem to have reached a stationary condition at one of the highest points in our history. During 1927 the rate in 122 American cities, having an aggregate population of about 35,000,000, was 10.4 per 100,000, which is slightly lower than the 1926 rate of 10.8. In 30 cities for which data can be secured as far back as 1900, the rate has increased steadily with few fluctuations from 5.1 in 1900 to 11.3 in 1924; since then, however, it has dropped to 10.1 in 1927.

There were no deaths in 1927 from homicide in Brockton, Malden, Newton and Somerville, Mass., Harrisburg, Pa., Lakewood, O., Lincoln, Neb., Newport, R. I., and Passaic, N. J. Low death rates of 1.0 or less were found in Camden and Elizabeth, N. J., and Lowell, Lynn and New Bedford, Mass. The highest murder rates were 69.3 in Memphis, Tenn., 63.0 in Birmingham, Ala., 55.5 in Charlotte, N. C., 54.0 in Jacksonville, Fla., 43.4 in Atlanta, Ga., 40.0 in Miami, Fla., and 39.7 in East St. Louis, Ill. The largest cities of the country with their congested slums and alleged rule of violence and crime had rates which were considerably lower than these southern cities. Boston had the lowest rate, 3.9, New York City 6.1, Philadelphia 8.4, Baltimore 10.3 and Chicago 13.3. Conditions in Chicago seem to be improving, however, for the 1926 rate was 16.7. An improvement is also apparent in Detroit, Mich., where the rate dropped from 25.3 in 1926 to 18.7 in 1927.

The mortality from homicide in American cities does not compare at all favorably with the rates of foreign coun-

tries. In 1926 the rate for England and Wales was 7 per million as against 104 for the American cities. The rate for Italy in 1925 was 44 per million and the corresponding rate for the United States Registration Area was 86. In the same year the Canadian Registration Area, which included all of Canada except the Province of Quebec, had a rate of 14 per million.

An analysis of the homicides of Jefferson County, Ala., was made for the years 1920-1926. During this time there were 560 deaths of males and 137 of females from homicide. The average age at death of the females was 25.8, for the males it was 31.9 years. Six hundred and eighty-nine of these deaths took place in Birmingham city but 19.1 per cent of the males and 15.6 per cent of the females were non-residents of the city. Seventy-five and seven-tenths per cent of the male deaths and 59.7 per cent of the female deaths were due to firearms while 66.2 per cent of the white persons and 74.4 per cent of the colored were killed in this manner.

The death penalty is enforced in much too small a proportion of cases and with too long a delay to be effective in preventing homicides. A study of the 10-year period ending with 1926, in 6 states that did not enforce the death penalty and in 5 that did, showed the average murder rate in the non-capital-punishment states to be 42 per million and 57 in the states which enforced the penalty. The number of deaths from homicide for each execution varied from about 36 in Pennsylvania and 44 in New York, to 170 in Ohio and 274 in Massachusetts. These statistics prove that the infliction of the death penalty falls on an insignificant

nificant fraction of the murderers in these states and that therefore the best purposes of justice would be served by abolishing the death penalty and substituting life imprisonment without opportunity of pardon or commutation of sentence.—Frederick L. Hoffman. *Spec-tator* 120:8 and 40-42 (Mar. 29), 1928.

London Vital Statistics, 1927—The statistical abstract published by the London County Council shows that the estimated population of the administrative county of London in 1927 was 4,550,000. That recorded in the last three censuses was 4,536,257 in 1901; 4,521,685 in 1911, and 4,484,523 in 1921. Greater London has increased in population from 6,581,402 in 1901 to 7,805,870 in 1921. The average birth and death rates per 1,000 population of the decennium 1841-1850 were 31.6 and 24.8, respectively, and the natural increase rate was therefore 6.8. In the quinquennium 1921-1925 the birth and death rates were 19.9 and 12.3, respectively, and the natural increase rate 7.6. The most striking fact is the fall in infant mortality from an average of 167 in the decennium 1841-1850 to an average of 71 in the quinquennium 1921-1925. The rate recorded in 1927 was still lower, 59. From 19,586 in 1917 the number of street accidents increased to 48,153 in 1926. The 1927 figures are not yet published, but it is feared that this ominous increase has been maintained. Accidents per 1,000 of population have risen from 2.61 to 6.71.—London's Moving Populace and Vital Statistics. *J. A. M. A.* 90:1489 (May 5), 1928.

Health of Pretoria, Union of South Africa—In the year ended June, 1927, the European population was 42,000 and there were 23,000 colored persons—Africans, Eur-Africans, and Asiatics. The European death rate was 7.0 per 1,000, as compared with 7.7 in the pre-

vious year. The death rate for the colored races was 16.0 per 1,000. The European infantile mortality rate of 49 per 1,000 births is the lowest on record for Pretoria; last year's figure, which is considered to be very low, was 2.5 higher. The infant mortality for all colored races was 315 per 1,000 registered births. The natives (Bantus or Kaffirs) suffered most heavily, their rate being 388.5 per 1,000, though this figure is an improvement on that of the previous year, which was 483 per 1,000. In Benoni the rate is quoted as 847 per 1,000, the number of deaths in native infants under 1 year in January, 1927, being equal to the number of births during the month. On the West Rand conditions, though bad, are better than on the eastern end of the Reef; in Krugersdorp last year the native infantile mortality rate was 320 per 1,000 births, but these figures undoubtedly exaggerate the state of affairs. Notification of native deaths is practically complete, but that of births is very defective.

Excluding imported cases the infectious diseases notified among Europeans were: typhoid 67 with 2 deaths, scarlet fever 25, diphtheria 20, measles 209, whooping cough 100, other infections 33; among non-Europeans: typhoid 26 with 8 deaths, diphtheria 2, measles 17, whooping cough 8, tuberculosis 13, other infections 8. Typhoid vaccine was administered to 1,497 persons—545 Europeans and 952 non-Europeans. Only 12 cases of malaria were notified in the municipality during the year; 8 of the patients had either come to Pretoria from elsewhere or had been infected outside the area.—*Brit. M. J.* Mar. 3, 1928, p. 370.

Health Conditions in Prussia During the Year 1927—Health conditions in Prussia, during 1927 were comparatively favorable. There were only two outbreaks of typhoid of any propor-

tions. The first outbreak, which was traceable to infected cheese, comprised 175 cases and 12 deaths. The second outbreak, which spread over seventeen towns and villages through contact transmission from patient to patient, included 155 cases and resulted in 14 deaths. As in recent years, there were frequent outbreaks of meat poisoning involving a considerable number of cases.

During the post-war period, diphtheria and scarlet fever were on the decline, but, during the past 2 years, they have increased. In 1927, the increase of both diseases was marked, while the number of scarlet fever cases, over 1926, was almost doubled. In the main, however, the diseases have run a mild course, so that the deaths have not increased in the same proportion as the morbidity. In Berlin and in some few cities to which the disease was carried, diphtheria appeared in a malignant form, and caused a case mortality of 12 per cent. In some parts of Prussia, especially in the sections of the province of Saxony that border on the Free State of Saxony, epidemic infantile paralysis was prevalent, evidently carried there from the focus of infection in Leipzig and vicinity. The number of cases and deaths was, however, considerably less than in 1926.

Puerperal fever still shows a comparatively high morbidity and mortality. Tuberculosis, which, during the post-war years, showed an increased incidence, appears to have been brought to a standstill; the number of deaths from tuberculosis has decreased. For a number of years, an increasing incidence of goiter has been observed in Prussia, particularly among the school children. In many sections of Prussia small quantities of iodine have been administered in an artificial manner, with undeniably good results, though it is too early to draw any final conclusions from these

experiments. The observations will be continued, with great interest and attention.—*J. A. M. A.* 90:1726 (May 26), 1928.

The Age Incidence of Appendicitis Operations—A study of 766 consecutive appendicitis operations in the past 20 years at the Claremont (N. H.) Hospital showed that 41 per cent were in persons between 20 and 30 years of age, 21 per cent were in the 10-20 age group, 20 per cent in the 30-40 group, 7 per cent in the 40-50 group, 5.5 per cent were under 10 and 5 per cent over 50 years. The 20-30 age group also showed the highest incidence, about 32 per cent, in 6,568 cases reported by questionnaire from different parts of Canada and the United States. Four hospitals in New England, however, had the most cases, 38 per cent, in the ages between 10 and 20.

Of the 37 cases at the Claremont Hospital occurring in persons over 50 years of age, 22 were in such desperate condition that the operation was performed as an attempt to save the life of the patient. All of these 22 cases had suppuration in some form; some gangrene, some a large amount of free pus and some a well developed peritonitis. Twenty-four of these 37 cases were male and 13 female.

The mortality rates at the Claremont Hospital were as follows: all ages, 3.6 per cent; under 10 years 4.8 per cent; 10-20 years 2.3 per cent; 20-30 years 2.2 per cent; 30-40 years 2.0 per cent; 40-50 years 4.1 per cent; 50 and over, 21.6 per cent. The mortality rates reported in the questionnaires varied from 1.9 to 4 per cent for all ages and from 19 to 50 per cent in all persons over 50.—Emery M. Fitch, *Appendicitis in People Over Fifty Years of Age. New England J. Med.* 198:348-351 (Apr. 5), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Methods Used by Oil Company Stop Pollution of Streams—At the El Segundo Refinery, the Standard Oil Company of California pumps about 20 million gallons of salt water daily from the ocean. The water is used for cooling purposes in the refining of oil. In its way through the refinery the water picks up a certain amount of oil from leaks and spills, etc. The oil is about 0.1 per cent of the volume of water used. This oil is removed from the water before latter is returned to the ocean. The article describes the method used in separating the oil and water by passing it through a tank or series of tanks or compartments and over skimming baffles. The action which takes place keeps the water and oil moving toward the surface, thus assisting and accelerating the movement of the oil to the surface where it is pumped off. The above plant removes all traces of oil from the water. Charles W. Geiger. *Water Works Eng.*, 81:90 (Jan. 18), 1928. Abstr. Frank Raab.

Deep-Pit Sludge Digestion at Indianapolis Sewage Works—Sludge is pumped at 7.72 and 1.12 per cent solids, respectively, to digestion pits. Pits are about 300 ft. square with a depth of 7 to 10 ft. The nature of the soil beneath the pits permits water to escape to such extent that it is only occasionally necessary to remove any quantity of free water, although skimming boxes are provided for the removal of liquor at any depth.

No chemical or temperature control is provided. A pit receives sludge until it is full, and the flow is then diverted to another pit until the first pit is lowered by filtration into the ground. This

brings about a series of intermittent fillings and effects some seeding. During filling periods pits become more acid, especially in cold weather.

Primary sludge enters the pit at a pH of about 6.8 and the activated sludge at 7.3. Under normal filling conditions the mixed sludge seldom drops during digestion below 6.8, and, on standing, without the addition of fresh sludge, goes to 7.8 and 8.0 in a short time. Above figures indicate conditions under which digestion usually takes place but hard and fast reaction and time figures cannot be given. Relative amounts of fresh and digested sludge and temperature govern the rate of reaction change.

A tabulation showing figures obtained in taking stock of sludge in the various pits is given. The large reduction in volume is attributed to the nature of the soil underlying the pits and the extent of digestion of solids to the long period of time involved, although the method of filling produces a mixture of some very old and some very fresh sludge in each pit. The mixture has never drained to less than 80 per cent of moisture and for the most part a moisture content of about 85 per cent obtains.

The author believes that as the proportion of activated sludge increases, satisfactory draining becomes more difficult and that drying beds will be required to put sludge in a condition to be handled. The present use of sludge by growers has not solved the problem of disposal but its use may be developed and extended as growers become familiar with its advantages.—C. K. Calvert, *Eng. News-Rec.*, 100:230 (Feb. 9), 1928. Abstr. C. H. Kibbey.

The Ozone Fallacy in Garage Ventilation—Dr. Salls presents a discussion of the literature concerned with the reaction of carbon monoxide and ozone, and from this discussion one must conclude that there is great variance in the literature concerned with this reaction.

The experimental studies which Dr. Salls presents are analyses of the atmosphere from a gassing chamber, in which carbon monoxide is mixed with ozone at room temperature. The atmosphere was sampled from the beginning of the mixture of the gases to a period 140 minutes thereafter. The carbon monoxide determinations were made by means of the Sayers-Yant method, using defibrinated steer's blood as a blood reagent. Three samples of the atmosphere were obtained prior to starting the ozonator, the three samples yielding the following results in chronological order: 13, 9 and 7 parts of carbon monoxide. After allowing the ozonator to operate for about 20 minutes, a sample was taken which yielded somewhat less than 5 parts of carbon monoxide. Subsequent samples were taken to the end of 140 minutes. When these samples were plotted against time they fell on a fairly uniform curve which appears to be the curve of absorption of gas by the chamber walls and leakage through them. The starting of the ozonator appears to have in no way altered the shape of the curve.

Dr. Salls concludes that this study indicated no evidence of an appreciable action of the ozone on the carbon monoxide.—Carroll M. Salls. *J. Indust. Hyg.*, 9:503 (Dec.), 1927. Abstr. Leonard Greenburg.

Preventing Excessive Smoke—One of the most important discriminations in the field of smoke abatement, so far as railroading is concerned, is the differentiation between smoke prevention and "smoke painting" or white-

washing. The latter is merely a method of discoloring smoke by means of wet steam or vapor, whereas the former, the correct method, requires improved combustion for its treatment. The author further points out that smoke burning or smoke combustion are misnomers because smoke already formed ordinarily cannot be burned or consumed. The greatest difficulty in avoiding smoke is usually on switch or transfer engines, owing to the nature of their work, and on road engines starting out from their terminal. Here it is necessary to rely on the blower and "smoke burner," by means of which additional air is admitted to the fire box, this air serving to prevent the formation of smoke. When the steam jets are used in the fire box without inducing the flow of additional air into the fire box, the steam jets merely serve to paint the smoke and not to prevent it.

In addition to this generous supply of air, a sufficiently high fire box temperature is necessary to prevent smoke formation. And finally, it is to be pointed out that the proper method of firing has considerable influence on smoke formation. Only a sufficient amount of fuel should be placed in the fire box at each firing as will insure proper combustion.—J. F. Bjorkholm. *Railway Age*, 84: 357 (Feb. 11), 1928. Abstr. Leonard Greenburg.

Iron and Manganese Removal at Wausau, Wisc.—This is a description of a 3-4.5 m.g. iron and manganese removal plant, costing \$125,000. Well water of poor physical character is being effectively treated by aeration, coagulation and sedimentation, and filtration. Final chlorination is not needed. The aerator consists of shallow wooden racks, holding 5 inch layers of coke and 2 inch layers of manganese dioxide ore, which are arranged in vertical tiers. The aerated water is dosed with 7.4 g.p.g. alum and 3.5 g.p.g. lime before dis-

charge through a baffled mixing chamber into a 45' x 45' x 16' Dorr clarifier, and then into three sedimentation basins, each 36' x 45' x 14' in size. Six rapid sand filters are fitted with porous concrete slab underdrains capable of passing 150 g.p.m. per sq. ft. Slabs are bolted to concrete stringers and have joints cemented. Slabs were made of $\frac{3}{4}$ to 1 inch gravel. A gravel layer of this size is used over slabs to depth of $6\frac{1}{2}$ inches; then one of $\frac{3}{8}$ to $\frac{5}{8}$ inch size for a depth of 3 inches; and then one of $\frac{1}{8}$ to $\frac{3}{8}$ inch size for a depth of 3 inches. Fine sand to depth of 28 inches is placed upon gravel. Complete control and recording apparatus is provided. From $2\frac{1}{2}$ to 3 per cent wash water is used, which is somewhat high because considerable fine floc reaches the filters.—Emil Flatter. *Am. City* 38:125 (Mar.), 1928. Abstr. C. R. Cox.

A New Larvicide for Mosquitoes—The authors experimented with chemically pure borax, with crystalline and calcined sodium borate, and with commercial borax. The latter was found to be as efficient as any. After experimenting with various concentrations, the authors conclude that ordinary borax in the concentration of 1.5 gm. per liter of water proved an efficient larvicide for mosquito larvae. This retains its action for long periods of time in wooden pails. Borax did not stop egg laying and hatching, but in no case did the young larvae live for more than 2 days.

They quote reports that borax pools do not produce mosquitoes and that, in a borax country, this substance is not absorbed into the ground but crystallizes

on evaporation of the water and is ready for the next rain. The authors suggest that there is a field of usefulness for borax as a larvicide, in such places as fire barrels, etc.—Robert Matheson and G. H. Hinman. *Am. J. Hyg.*, 8:293 (Mar.), 1928. Abstr. L. L. Williams, Jr.

The Role of Ammonia in the Purification of Water—During the 1925 maneuvers of the British Army, Major Harold introduced a new method of purifying water. This method assisted in preliminary treatment with ammonia followed by sterilization with chlorine. In this way the absorption of chlorine is restrained and its germicidal powers are enhanced. The sterilizing agent is not unduly deviated by organic matter and a safe water is produced, practically free from unpleasant tastes. The chlorine solution was given initial contact with the ammonia prior to dosing into water and the highest concentration which did not show evidence of available chlorine was fixed upon as the optimum. Two compounds were produced by the interaction of 1 equivalent of chlorine with $\frac{1}{2}$ an equivalent of ammonia. In a foul water containing urine and nitrites in unreasonable amount some absorption of mono-chloramine was evident but with all casual waters encountered a dose of 1 p.p.m. has always sufficed. Dichloramine is slower in action but possesses greater stability than mono-chloramine. Normally each water cart having a capacity of 110 gal. is dosed with 1.25 gm. of ammonium bicarbonate and about 3 gm. by weight of dry chlorine gas.—C. H. H. Harold. *J. Roy. San. Inst.*, 48:484 (Mar.), 1928. Abstr. W. L. Havens.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH.D.

Industry and Public Health—One concern employing 4,500 employees found, before instituting medical service, that they were losing from cost of illness due to sickness \$67,500; cost of absence from sickness, \$150,000; production loss from sickness on the job, \$50,000; loss to workers in wages, \$162,000; loss through reduced earning capacity, \$40,000; medical expense to workers, \$45,000; public expense and charitable relief, \$56,000; total, \$570,500.

The justification for industrial medicine lies not only in the reduction of absences from sickness, but also in the prolongation of lives of usefulness of the older and more experienced employees. We have no statistics on this subject, and it will be a long time before the ultimate effect can be appraised.

Statistics further show that the average industrial worker is absent from duty 6 to 9 days each year due to insignificant ailments. In the case of salaried workers this loss falls wholly on the industries; while in the case of hourly paid workers the loss is divided—the worker losing the wages, the concern the output.

When absenteeism lasts so long as to require workers being replaced, the loss to the industries increases heavily. Estimates vary as to the cost of hiring an employee, but besides the first cost, wastes of one kind and another are involved. Often the worker is no better in health than the one replaced. The accident hazard is increased, output lessened, and defective work increased. Here is another economic reason why big business is interested in health.

As to results accomplished from the direct application of health work to in-

dustries, the Metropolitan Life Insurance Company's figures are probably more accurate than any others we have. Its statement for the year ending December 31, 1926, shows that lives saved among industrial policy holders from 1911 to 1925 in excess of general mortality improvement numbered 240,000; lives saved among policyholders in 1926, as compared to the death rate in 1911, numbered 63,330. In other words, by the application of protective health measures to industrial workers it paid 63,330 fewer death claims. This means that not only fewer death claims were paid, but it also means happiness and well-being for thousands of families.—T. F. Abercrombie, Proceedings of the Fourteenth Annual Meeting of International Assoc. of Industrial Accident Boards and Commissions, Atlanta, Ga., Sept. 27-29, 1927, *U. S. Dept. of Labor, Bur. of Labor Statistics. No. 456*, Feb., 1928, p. 135.

Cancer Statistics as They Appear to a Pathologist—The author presents many arguments bringing him to the conclusion that the increase in the cancer rate is just about the same as the increase of the other three common causes of death in those who have passed the prime of life; namely, cerebral hemorrhage, nephritis and heart disease. Also diabetes, which is chiefly an old age disease shows the same trend. "I find myself unable to accept anything about cancer as finally established by statistics."

I am not by any means sure that changes of habits and occupations may not be having some influence on the incidence of cancer. For example, a smaller proportion of the population are now engaged in outdoor occupations,

which theoretically favor the development of cancer of the skin of the face. Chimney sweeps' cancer may be decreasing or vanishing with modern house construction and heating in the countries where it once occurred. Bladder cancer may be increased as an industrial disease through the development of dye factories. Perhaps changes of diet or culinary technic may influence the occurrence of cancer of the stomach—but in which direction there is no reliable evidence. There seems to be little doubt that primary cancer of the lung is now a more common disease in Europe and America than it was even ten or fifteen years ago. If this is a sequel of influenza, as some believe, the increase should be transitory; but if it is the result of irritating chemicals from industrial processes, or the dust from tarred roads, which are among the possible exciting causes, the increase in this form of cancer may become permanent and significant. So perhaps there are changes in the incidence of cancer, independent of the increased age level of the population. My object is not to deny the existence of an increased incidence or to establish the existence of a decreased frequency, but merely to indicate how unconvincing the evidence appears to one whose daily observation impresses him with the inaccuracy of the recorded statistical data.

—H. Gideon Wells, *Studies from the Otho S. A. Sprague Memorial Institute*, Collected Reprints, Vol. XV, 1927, 31 pp.

Caring for Injured Workers—This *Bulletin No. 82* of the Series of Safe Practices Pamphlets discusses the necessary equipment and attendance for first aid and other care of injured workers. The article is profusely illustrated and has been prepared by a special committee having the benefit of great experience in accident prevention and first aid. The report is in the form of a code.—*National Safety News*, Mar., 1928, pp. 23-32.

Iron Foundry Workers Show Highest Percentage of Deaths from Pneumonia—This article presents a table covering 15 occupations which shows deaths from pneumonia standardized for ages 15-64 years with iron and steel molders and foundry workers at the head, having a percentage of 17.6 as against the next in order, cordage and kelp mill operatives, with a percentage of 14.8. Coal miners (underground) have a percentage of 12.0 deaths due to pneumonia in all cases of death. Coal miners (underground, except coal) are at the foot of the list with 9.4 of deaths due to pneumonia. The article points out that only 7.7 per cent of deaths among all occupied males are attributed to pneumonia. For iron foundry workers the percentage of deaths is well above the average at every age from 15 to 64 years. In the age period 25-34, it is over three times the average. Pneumonia was the chief cause of death among them. This is true of no other occupational class included in the Metropolitan investigation. The article notes that the workers listed in the table have three distinct types of hazards; namely, dust, extreme heat, and sudden variation in temperature and exposure to weather. Similar comparisons with ten occupations in the British industry show the highest death rates from pneumonia in order of magnitude as brass foundry laborers, grinders and cutlers, stevedores, cotton glow room operatives, iron foundry furnace men and laborers, cotton carders, puddlers, metal polishers, and "other" dock laborers.—*Metropolitan Life Insurance Company Statistical Bulletin*, IX, 3:1 (Mar.), 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Vitamins of Orange Juice—Only recently has investigative work shown that orange juice contains other vitamins than the antiscorbutic C. The juice was obtained from ripe California oranges which were peeled before pressing to obviate contamination of the juice by the oil known to be rich in vitamin A. The juice was filtered free from cell tissue. Doses of orange juice, 7.5, 5.0, 2.5 c.c. respectively in the case of rats which had evidence of vitamin A deficiency by development of xerophthalmia, indicated that the dose of 5.0 c.c. or more met with prompt response, while the animals receiving 2.5 c.c. died in 3 weeks from vitamin A deficiency. This was confirmed by a second experiment, employing positive and negative controls, positive being supplied with potent cod liver oil. The negative control died and experimental animals receiving 5 c.c. orange juice compared favorably with the positive in appearance and as indicated by autopsy. Preliminary experiments show that doses of 5 c.c. orange juice were insufficient to supply rats with vitamin B. This was checked with positive and negative controls, the positive controls receiving an equivalent of 0.6 gm. of marmite extract. Animals receiving daily doses of 7.5 c.c. of fresh juice showed a tendency to fall off in growth after the third week. The dose was raised to 10 c.c. which was continued and there was little difference between these animals and the positive control. The autopsied rats were normal. The juice was tested for vitamin D by the Zucker technic in which the fecal reaction is made alkaline by rachitogenic diet. Antirachitic substances fed at this time convert the reaction to acid within 3 to 4 days, and the per-

sistence of alkalinity is regarded as indicative of the absence of vitamin D. After feeding doses of 10 c.c. per day of fresh orange juice for 2 weeks the fecal reaction was still alkaline. Supplements of cod liver oil potent in vitamin D changed the reaction to acid within 4 days, but of those on orange juice it remained alkaline, indicating probable absence of vitamin D. While the author concludes that the study on vitamin D should be repeated, it was pointed out that chemical experiments showed that children may develop rickets even when taking appreciable amounts of orange juice.—S. G. Willimott, *Biochem. J.* 22:67, 1928.

Iron in Nutrition. VI. Iron Salts and Iron-Containing Ash Extracts in the Correction of Anemia—A series of experiments is recorded, undertaken for the purpose of correcting a nutritional anemia developed in young rats in a stock colony which were weaned at from 3 to 4 weeks of age (50 to 60 gm. weight), and placed on a diet of cow's milk, anemia being characterized by very low hemoglobin levels. The effects of inorganic iron salts were studied, making use of a commercial chloride and a C. P. ferrous ammonium sulfate. The iron salts were fed at a level of 2 mg. of iron daily, 6 days a week, and later at a level of 0.1, 0.15, 0.5, and 1.0 mg. In no case did these small additions of iron correct the anemic condition, and all of the animals died after showing only slightly increased hemoglobin. The effect of iron in the form of ash and dried lettuce was also tried. The first feeding represents a level of 1 gm. of dried lettuce daily, 6 days a week, which was quite effective in

correcting anemia. Beef liver, kidney, and muscle, yellow corn, and wheat were selected for another experiment. The quantities of these animal tissues were sliced, dried, and ground and the corn and wheat were finely ground. All materials were fed at levels of 0.5 gm. per rat 6 days per week. This level in the case of beef liver introduced about 0.15 gm. of iron. Beef liver resulted in steadily increasing hemoglobin formation as well as good growth and physical appearance. Beef kidney was less favorable and beef muscle practically inert. Corn and wheat were less valuable and in most cases the animals died. Further experiments were initiated to determine reasons for the effectiveness of liver material. Various salts of iron, chloride, sulfate, acetate, citrate, and phosphate were prepared. These salts were fed at a level of 0.5 mg. 6 days per week. All of these salts failed to increase materially the hemoglobin, the majority of the animals dying in 4 to 8 weeks. Hydrochloric acid extracts of the ash of lettuce, yellow corn, and beef liver were made. These were compared in feeding experiments with ferric chloride and with the ash of liver ignited with calcium carbonate and were fed in such amounts as to furnish practically 0.5 mg. of iron. Marked hemoglobin regeneration resulted in all cases except with the addition of ferric chloride alone. It is concluded as a result of data that in addition to the iron which is essential the ashes and extracts of the ashes of corn, lettuce, and beef liver, contain some other substance necessary to restore hemoglobin, evidently inorganic in nature.—J. Waddell, C. A. Elvehjem, H. Steenbock and E. B. Hart. *J. Biol. Chem.*, 77:777 (May), 1928.

VII. Copper as a Supplement to Iron for Hemoglobin Building in the Rat—In the course of the study of the effect of iron salts on anemia (see preceding abstract) investigators obtained

a commercial preparation of liver which has proved effective in the treatment of pernicious anemia. This preparation is fed at a 3 gm. level, 6 days per week and at the same level supplemented with 0.5 mg. iron as ferric chloride. All animals responded, slightly better results being evident in those receiving the iron supplement. The ash and a hydrochloric acid digest of the ash were fed to anemic rats at approximately the same iron level and were found effective in correcting the anemia. The ash of a commercial liver preparation was fractionated into three parts, hydrogen sulfide precipitate, hydrogen sulfide—ammonium sulfide precipitate, and filtrate. The precipitates after solution in acid were evaporated taken up with water and, together with the evaporated filtrates suspended in water were fed at levels representing 0.3 gm. of the original preparation. The hydrogen sulfide fraction alone was potent. Previous to this experiment, the effect of copper as copper sulfate had been tried by addition to the whole milk diet, as a result of observing a pale blue color in the ash of some material which had been studied. The effect of this salt on one single animal feeding was remarkable as indicated by the weight record and hemoglobin curves. This suggested that the hydrogen sulfide fraction of the liver ash was the one containing the most copper and for that reason particularly potent. Experiments were undertaken with copper feeding at levels of 0.01, 0.05, and 0.10 mg. of copper as the dose per rat, giving 0.05 mg. of iron as ferrous chloride in addition. In the 0.05 and 0.10 mg. levels of copper, rapid recovery was noticed. A determination of the copper content of the commercial liver preparation showed 0.016 per cent copper. A discussion as to the presence of copper in the animal organism and the probable manner in which it functions conclude with the suggestion that it may act as a catalyzer for certain reac-

tions concerned in hemoglobin building and that the work emphasizes the necessity for a more intensive study of the effects of small amounts of inorganic elements in nutrition.—E. B. Hart, H. Steenbock, J. Waddell and C. A. Elvehjem. *J. Biol. Chem.*, 77:797 (May), 1928.

Chemical Composition of the Milk of Cows Receiving Cod Liver Oil—This is a preliminary paper, recording experiments carried on over a period of 5 months, on 4 cows which received cod liver oil and peanut oil, all on similar rations. The quantities of the oils administered are given and also the complete analyses of the milk from the cows. Results indicate that the cows receiving cod liver oil produced milk which contains an increased percentage of total calcium. Results are regarded as insufficient to justify definite conclusions but the fact that previous investigations have shown that butter from milk of cows on cod liver oil supplement is much more antirachitic than butter from cows not receiving cod-liver oil, probably warrants further study which is in progress.—Elfrida Constance Victoria Mattick, *Biochem. J.* 22:9, 1928.

Studies On the Effect of Heat On Milk. IV. The Iodine Content—This work was undertaken in view of the reports that the reduction in the soluble calcium in milk by heat adversely affects metabolism and may eventually give rise to rickets in young animals and in children. Cod liver oil is stated to improve the growth promoting properties of heated milk. Since this is rich in iodine this study is suggested. Sep-

arated cow's milk, fresh, pasteurized, and boiled, was prepared and the iodine determined by the Leitch-Henderson modification of Fellenberg's method. The iodine averaged in micro-milligrams per 100 c.c. 5.69 for fresh, 4.51 for pasteurized, and 4.23 for boiled.

Both cow's milk and goat's milk were dialysed in determining the amount of iodine diffusible. It was practically the same in both, or 83 per cent of total iodine.—Hugh Edward Magee and Agness Elisabeth Glennie, *Biochem. J.*, 22:11, 1928.

Value of Whole Potato in Human Nutrition—Reference is made to the work of Hindhede who, with his collaborators, was able to live over long periods of time in which nitrogen was derived solely from the potato. His investigation is here repeated, continuing the experiment for several months. The subjects were two healthy adults, a man aged 25, and a woman aged 28, both doing laboratory work. The diet consisted of potato with butter or pork fat with the addition of apples, pears, tea or black coffee with sugar. The amount of fat consumed was from 120-150 gm. daily. Potatoes were steam-cooked. The experiment extended over 167 days and the nitrogen balances are submitted. The nitrogen content of the potatoes was 0.34 per cent. Nitrogen equilibrium was attained by both subjects and a daily intake of nitrogen was slightly under 5.6 gm. for the man and 3.5 gm. for the woman. The authors conclude this is a confirmation of Hindhede's experiments, indicating the high value of potatoes as a sole source of nitrogen for the human adult.—Stanislaw Kazimierz Kon and Aniela Klein, *Biochem. J.* 22:258, 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

Tuberculosis in Infancy and Childhood—The time is coming, says Dr. Shapero in his article with the above title, when we can expect to see the control and perhaps the elimination of tuberculosis. This will be brought about by attention to the disease in the child. The author's conclusions are worded by him as follows:

1. Tuberculosis is usually due to human tubercle bacilli and most often gains entrance by inhalation. Inheritance plays practically no part in the perpetuation of this disease.

2. Bovine infection occurs in 25 per cent of the cases and is oftener present before than after 5 years of age.

3. Contact with tuberculous patients is of preëminent importance in the spread of tuberculosis. Milk plays a minor rôle. The earlier the contact, the more likely the infection develops; the earlier the infection occurs the greater are the chances for disease production and, furthermore, the earlier the disease, the graver becomes the prognosis.

4. A positive tuberculin reaction in the older child does not necessarily mean disease, but denotes past infection. A positive reaction is obtained in 80 to 90 per cent of all children under 15 years. Under 2 years a positive reaction usually signifies disease.

5. The child mortality under 12 is directly due to tuberculosis in 15 to 30 per cent. The mortality from pulmonary tuberculosis has diminished, but meningeal and miliary tuberculosis still play havoc with the infant. The prognosis is better at present than it formerly was.

6. The symptoms of tuberculosis are as a rule disturbances of nutrition and general well-being.

7. The X-ray is of great assistance in diagnosing this condition.

8. Heliotherapy and tuberculin are beneficial in selected cases when used with proper care.

9. There is neither an absolute nor a natural immunity to tuberculosis, skin sensitiveness resulting only after infection.

10. The prevention of tuberculosis in infancy and childhood depends on avoidance of contacts under the age of 2. There should

be a careful supervision of the milk supply. If prevention is at any time possible with Calmette's B.C.G., the most fruitful time for such is just following birth. Measles and pertussis should be prevented in infancy as these usually light up an infection and produce disease. The most favorable time of exposure is between 3 and puberty since the lymph glands function best at this time.

11. Physical defects such as posture, dental caries, hypertrophied diseased tonsils should receive attention and correction.

12. The time is not far distant when tuberculosis will be better controlled and possibly eliminated.—

Tuberculosis in Infancy and Childhood, A. A. Shapero, M.D., *Arch. Pediat.*, May, 1928.

The Health of Rural School Children—Dr. James Frederick Rogers of the Federal Bureau of Education describes Ten Steps in the Promotion of Health in Rural Schools. Starting out as Step One, with a real desire for health as a genuine as well as theoretical objective in education, he goes on to enumerate as Step Two the backing of the board of education and support of local groups such as Parent-Teacher Associations, physicians and dentists. Then follow the distribution of educational leaflets; utilizing existing agencies; surveying the school plant to decide what changes are needed, and acting on the recommendations which come to the fore after the survey has been completed. Step Six involves health examinations, both medical and dental. Step Seven translates the results of the physical examination into active participation in the formation of health habits. Step Eight has to do with the improvement of the nutrition of the child through the employment of the school lunch. Step Nine brings us to the playground as a

field of activity for physical education. Lastly, Step Ten has to do with the type of expert supervision which should be given to keep the health program moving forward as rapidly as it should.—Ten Steps in the Promotion of Health in Rural Schools, James Frederick Rogers, M.D., *School Life*, XIII, 10 (June), 1928.

Baby Week in the East—From far off Delhi in India comes the story of an annual Baby Week held in a nice shady garden under the walls of a fort. Not only were the babies themselves present but there were exhibits showing what the normal baby needs to keep him well and comfortable, food charts, and even a laundry demonstration. A model street with a covered well, a bin for refuse, and clean shops where protection from flies was carried out, was contrasted with the ordinary dirty Indian street with all that accompanies it. The element of competition is brought in through an annual reward of a silver cup for the most effective local health and Baby Week campaign held anywhere in India.

Maternal Mortality—Investigations into the causes of maternal mortality have become less uncommon in this country than they used to be. They apparently do not arouse any undue amount of antagonism on the part of the practicing physician, provided these studies are carried on with discretion.

The *Journal of the American Medical*

Association, however, reports a joint letter to the *London Times* from leading obstetricians who deprecate the suggestion that the local health authorities undertake an investigation into the lack of reduction of mortality of childbirth. The point they make is that this type of study is not likely to offer any solution of the problem, since in their opinion it is in the nature of an attempted short cut to a solution which has baffled explanation throughout the world for many years.

It is well recognized by these critics that puerperal fever is infectious but they maintain that it is still a matter of controversy as to what proportion of cases arise from a latent infection within the patient herself and what proportion from infection carried to the patient. There is also the problem of the factors which determine susceptibility to infection and of the part played by lowered resistance of the patient. Certain anomalies are pointed out: why should a rapidly fatal infection follow an absolutely natural childbirth at times, while an uneventful recovery may follow complications of a nature to arouse expectation of unfavorable results. Toxemias too have their puzzling aspects.

The conclusions which the practicing obstetricians reach are that a close alliance is needed between the physician, the biochemist and the bacteriologist, and also financial assistance for the establishment of clinics and laboratories.—*Foreign Letters, J. A. M. A.*, May 19, 1928.

Prize Competition for a Book on Child Hygiene

THE Royal Society of Hygiene of Milan, Italy, has announced a prize competition, open to the physicians of Italy, for the best handbook on the hygiene of children between the ages of

7 and 15 years. A prize of 5,000 lire will be given to the winner. This book is to form a part of a series on maternity and child hygiene.—*Pediatrics*, Naples, Dec. 15, 1927, p. xxxii.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Portable House for Office and Health Center—The *Health News* of the New York State Department of Health, has an account of the way an ingenious nurse in Putnam County, N. Y., solved the problem of headquarters. The suggestion might well be followed by other county public health nurses in the great open spaces where, seemingly, office spaces are frequently lacking.

The idea of having a portable house for use as a combined office and health center was fostered by the nurse and eagerly embraced by the committee on nursing activities after eliminating all other possibilities. The enthusiastic group purchased for \$664.00, including delivery, a house 18 by 21 feet. On land loaned for the purpose, interested members of the community assisted in putting up the structure.

The house was lined with sheet rock as a protection against the cold weather, and a stove was found to heat the building adequately for the monthly health conferences. It was wired for electricity, and the outside given two coats of white paint. Practically all the furnishings were donated. The total cost of the house, exclusive of equipment, was \$1066.00.—Public Health Nurse Uses Portable House for Office and Health Center, *Health News* New York State Dept. of Health 5, 23:90 (June 4), 1928.

The Frontier Nursing Service, Inc.—The Third Annual Report of the Frontier Nursing Service, Inc., is contained in the *Quarterly Bulletin* for June. This booklet of 60 pages gives a detailed account of the financial status of the organization, a statistical summary of the nursing service for each center and a list of the contributors. The

latter lists impartially gifts ranging from veterinary advice to thousands of dollars.

Something of the struggles of the first two years we know. One brief paragraph in the foreword sums up the progress which has been made in construction during the past year.

The work of the Service has been greatly augmented by its building program during the past year. The Up River Center (Jessie Preston Draper) is finished; the Possum Bend Center (Frances Bolton) was entirely built; the Hyden Hospital and Health Center has been carried nearly to completion, and the preliminary arrangements are made for the new center (Clara Ford) in Clay County, on Red Bird River near the mouth of Big Creek.

The hopes for the future health of the citizens of Leslie County lie in these rugged strongholds, through which the nursing service is administered. The centers are all located on mountain trails, anywhere from 6 to 34 miles from the railroad.

The new hospital and health center at Hyden, Ky., is within a month of completion. It is to have two wards of 4 adult beds each, with space for as many children's beds, and for at least 25 additional patients for special clinics. An operating room, a laboratory for the health officer, a dispensary and waiting room, and suitable kitchens, supply rooms and baths are listed among the special features of this new structure. Sleeping quarters and living quarters are provided for the nurses of the district service, the supervisor and a book-keeper.

Note: Previous to the Biennial Nursing Convention at Louisville, Mrs. Breckinridge issued a cordial invitation to the nurses who were attending the convention to visit the centers. Twenty-five guests could be accommodated and the visitors were to travel from

the railroad to the various centers either on horseback or by mule teams.

Who can foresee what this taste of frontier life will do toward enlisting staunch support and even recruits for service. A sense of romance and love of adventure still appeals to nurses, young and old.

Preschool Education—The major part of the June number of *The Public Health Nurse* is devoted to an interesting discussion of the present-day movement in preschool education. In the leading article, Education of Preschool Children, Dr. Lois Hayden Meek, Educational Secretary of the American Association of University Women, describes the different phases of the movement which have been developed in adapting education to the tiny child's needs. With the acceptance of the discoveries of psychologists that the formation of a child's personality and character begins at birth and is well on its way to good or bad by the time the child enters school, and that in teaching, the life of the child must be considered as an integrated whole, there has come a marked change in educational methods.

Nursery schools have developed in ever increasing numbers, modelled first on the English plan, but gradually being changed to meet American needs. Here the child's life, play, health habits, contacts with others, all the daily mental and emotional experiences are under the guidance of a trained, understanding person during the hours of school. But with the recognition by both parents and educators that those hours constitute but part of a child's day and that the greater part of his training still goes on at home, a concerted effort has been made to provide for parental education at the same time. Individual conferences over individual child problems, group discussions, lectures, and selected readings about the various needs of a growing child have been tried successfully in many places.

For special behavior problems, many

communities now have behavior clinics under trained psychiatrists, while medical clinics are used for all children for the maintenance of physical health which is fundamental to any sound growth.

Many nursery schools are also training centers for teachers, and as we are becoming better equipped with well rounded-out nursery school centers, more and more teachers are taking their entire training in this country.

In a field so new, we are not yet completely equipped with a background of exact knowledge about the life of the normal child. Therefore, highly important in the new educational movement are the research studies which are being made of child behavior and normal development, mental, physical, emotional and social, with interpretation of them from the basis that "the child's life is an integrated whole."

Anna Heisler, of the American Child Health Association, in the next article, Classes in Child Care for Children, discusses ways that are being tried to provide a preparation for the coming generations of mothers by teaching the fundamental principles of child care to girls in school. Perhaps ultimately the public school curriculum will include classes in child care for young girls and boys, with proper training of teachers for presenting this subject. Already some states report courses for teachers in infant or child hygiene. Wisconsin, particularly, has adopted a slogan "Every Girl Educated for Intelligent Motherhood," and the Bureau of Child Welfare, the State Department of Public Instruction, the State Board of Vocational Education, and the State Board of Normal Regents are combining in an effort to provide adequate courses in infant and child hygiene for school girls.

In home economics courses in many states, instruction in child care is included.

Apart from such formal teaching,

which has not been extensive, much has been done through Little Mothers' Leagues and Red Cross home hygiene courses to give young girls an opportunity to learn some of the fundamentals of sound motherhood.

In an article by Isabel W. Baker, of the American Red Cross, Bringing up Good Husbands, it is shown that not only girls but also boys are responding eagerly to home hygiene classes and are learning how to care for little children.

There are other articles, one suggesting functions for the public health nurse in the nursery school, and one describing the nursery school at Vassar College, which is being conducted in connection with the Department of Euthenics.—*Pub. Health Nurse*, 20, 6 (June), 1928.

News from the Biennial—We have heard from good authority that 4500 nurses registered at the convention. Forty-eight states were represented, as were also Canada, Cuba, Porto Rico and Hawaii. Eighty lay members of public health nursing associations were in attendance with representation from 22 states.

The following were elected officers and directors of the National Organization

for Public Health Nursing for the next 2 years:

President—Anne L. Hansen

Vice-President—Winifred Rand

Second Vice-President—Sophie Nelson

Directors—Nurse Members—Alta E. Dines, Ann Dickie Boyd, Gertrude Bowling, Grace Ross

Directors—Sustaining Members—Mrs. Chester C. Bolton, Mrs. C.-E. A. Winslow, Anna Huber, Mrs. John A. Haskell, Dr. Ira V. Hiscock

Nominating Committee—Mrs. T. Kraker Guthrie, I. Malinde Havey, Naomi Deutsch

Dr. May Ayres Burgess, Director of the Committee on the Grading of Nursing Schools, presented her report in a masterly way. The complete report may be found in Dr. Burgess's book—*Nurses, Patients and Pocketbooks*.

A Lay Members Section in the National Organization for Public Health Nursing was formed and is an important feature of the Louisville Biennial. The adoption of a Manual for Board Members will standardize the form of organization and of boards and committees.

The Public Health Nurse will contain more complete reports of the section meetings.

Milwaukee has been selected as the city in which the 1930 Biennial Convention will be held.

Open Air Schools

AS a means of improving the health of underfed or sickly children of school age, 3 open air schools have been established in Montevideo, Uruguay. These schools are situated in parks on the outskirts of the city. The school physicians select the children for admission to them. The children spend from 6 to 8 hours a day in the schools, summer and winter. The program is arranged so that class periods alternate with rest periods in

bed, both of which are held in the open air.

The children are weighed weekly, measured quarterly, and health records are kept, also nourishing meals are provided.

The three schools accommodate 600 children, whose average stay is 6 months.—*Boletín del Instituto Internacional Americano de Protección a la Infancia*, Montevideo, Oct., 1927, p. 199.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Your Publicity Program for 1929—The steps to take in preparing a year round program of health publicity will be discussed in a meeting which will run through two sessions of our section program at the A. P. H. A. convention in Chicago next October. In preparation for this meeting the program committee will welcome copies of publicity plans or outlines used by health departments and health organizations. Send to the editor of this department.

In a series of brief talks speakers will analyze the problems which come up when publicity is in the planning stage. On what basis do you choose your objectives? How select and classify your audiences? What tests of reliability and appropriateness determine your choice of talking points? How will you find the best method of approach to your audience? Which of the 57 varieties of publicity methods will you use? How prepare a schedule or calendar? Come and take part in the discussion and also make this meeting an occasion for starting to map out your 1929 program.

A New Weapon Against Typhoid

—State departments and state associations are provided with some good material in the recent news from Albany, N. Y. As discussed in the Law and Legislation Department (Apr. and June, 1928), the City of Albany must pay damages because of disease contracted through the municipal water supply.

The immediate strategy is to give widespread publicity to the mere fact of those awards being given by the courts. The more people know the pos-

sibility of such damage suits from typhoid victims the better will state or local forces seek safer water supplies.

MOTION PICTURES

Seven half day showings of general health and mouth hygiene pictures at the American Dental Association meeting, Minneapolis, Minn., Aug. 20-23 will give an opportunity to see many of the old and new films. Write to 58 East Washington St., Chicago, Ill., for detailed program.

The cartoon film, Health Twins at Work, which was made for the American Social Hygiene Association several years ago, has been edited and brought up to date, with its main interest centered on tuberculosis.

The scene opens on a courtroom where the judge, representing Public Opinion, presides. Two sprightly clever little men, the public health twins, are introduced respectively as Science and Administration, with the explanation that "the control of disease depends upon science and administration." The judge orders the three culprits, tuberculosis, infantile diarrhea, and diphtheria to stand before him, and when they have taken their places, all else of the scene except the three prisoners fades out and the caricature of tuberculosis slowly dissolves into a vertical bar. In quick succession the other two figures are likewise transformed into vertical bars, the resulting pictures being a bar graph of the mortality rates of the three diseases in 1900, each bar being carefully titled and of proper height in relation to the other.

Prints may be purchased through the American Social Hygiene Association, 370 Seventh Ave., New York, N. Y.

AWARDS

An Honor Roll of Cities having no accident fatalities during the preceding month is published in *Public Safety*, National Safety Council, Chicago, Ill.

*Editorial assistance in preparation of printed matter, and all other matters which require editing, etc., to E. G. Routzahn, 112 East 222 St., New York, N. Y.

In the belief that there is no sharper tool of social and civic betterment than a cartoon which combines a penetrating idea with good art, the Harmon Foundation offers through *The Survey* 16 awards for cartoons during the year beginning April 1, 1928. The only restriction as to subject is that the cartoons must, in the opinion of the judges, bear a direct relation to subjects which tend to make of our American communities better places in which to live and to work. An award of \$250 to be made quarterly and three awards of \$50 each, also to be awarded quarterly, are described in the announcement. Address, Harmon-Survey Cartoon Awards, 112 East 19th Street, New York, N. Y.

Wild West, by Viola Paradise. *Pictorial Review*. April, 1928. This short story won first place in the contest conducted by the Committee on Publicity Methods in Social Work. Based on the author's field experiences while with the Children's Bureau the story develops in dramatic fashion a phase of the need for rural maternity service. Miss Paradise has had numerous stories and articles in *Colliers*, *Harpers*, *Atlantic* and *Forum*.

NEWSPAPERS

Again *Editor and Publisher* issues its International Year Book edition with lists of dailies in many countries; city and Sunday editors named for many United States and Canada dailies; numerous classified lists; art and literary markets in the United States; books, schools, syndicates, mat and cut services, etc., 352 pages 10 by 13 inches. Jan. 28, 1928. Times Bldg., New York, N. Y. \$4.00 with year's subscription.

Fair and wise policies in dealing with the newspapers in emergencies are outlined in "Helpful Relations with Local Newspapers," by F. H. Williams. *Trained Nurse*. Oct., 1927. Especially important are the detailed suggestions as to information to be supplied in writ-

ing, and the handling of telephone interviews.

HONORABLE MENTION

Health, New Hampshire State Board of Health: for list of contents on cover page.

Fifth Annual Report of Quebec Provincial Bureau of Health: for a table of contents (called an index).

REQUESTS

Outline diagrams of the digestive tract are desired by Mabel Milhan, Home Demonstration Agent, Canton, N. Y. Please send your answer also to editor of this department.

Copies of posters and other material, as well as suggestions helpful in preparing a health exhibition will be appreciated by Dr. T. N. Mazumdar, Health Officer, Calcutta, India.

"On the average, what proportion of a welfare or nursing budget do you think might well be devoted to publicity purposes?"

Copies of The Cheapest Health Insurance, a 4-page folder, are sent by Dr. Robert E. Plunkett, Division of Tuberculosis, New York Department of Health, Albany, N. Y., in response to a "request" in the May issue. It embodies an interesting idea for boosting health examinations which is used in connection with consultation chest clinics. Whenever the family history shows illness at home, copies of the folder are given to the patients for the sick ones.

The Association of Social Workers, Prague, Czechoslovakia, is planning "an exhibition of posters representing the propaganda for social service" in different countries. They say:

It would be a great honor for us if your association would be represented by placards and posters which you may have issued, and we beg you therefore to kindly send us copies. We, of course, agree to pay all expenses regarding postage, etc., etc., or if preferred would send copies of our posters in exchange.

Please tell the editor when you mail your posters.

LAW AND LEGISLATION

JAMES A. TOBEY, LL.B., DR. P.H.

A Plan for Federal Child Welfare Extension—The original Sheppard-Towner Law, or, more properly, the Federal Maternity and Infancy Act, was passed on November 23, 1921, to take effect for a 5-year period ending June 30, 1927. Near the end of this period, Congress was importuned to continue the operation of the act for several years and after considerable wrangling agreed to a 2-year extension, but with the understanding that the law would positively cease on June 30, 1929. Both sides agreed to this.

During the closing days of the first session of the Seventieth Congress a bill, H. R. 14070, to provide a child welfare extension service in the federal government, was introduced by Representative Newton of Minnesota. This measure authorizes an annual appropriation of \$1,000,000 for the purpose of paying the expenses of a new division in the U. S. Children's Bureau. Only \$50,000 would actually be used for the administration of this service, the remainder of the million dollars being allotted to the states to promote the welfare and hygiene of mothers and children and aid in the reduction of infant mortality.

This proposition differs from the Federal Maternity and Infancy Act in that the states would not be required to match the federal funds, but the state, territorial, county, and municipal agencies, or child welfare associations could make voluntary appropriations for the purpose.

An Advisory Committee on Maternal and Child Welfare would be created by this proposed law. The committee would consist of the Surgeon General of the U. S. Public Health Service, the U. S.

Commissioner of Education, the Director of Extension Work of the Department of Agriculture, and the Chief of the Children's Bureau, as *ex-officio* members, and 5 other members to be appointed by the chief of the Children's Bureau, with the approval of the Secretary of Labor. These members would be from without the federal government and at least one would be required to be a state health officer.

The bill stipulates that no funds appropriated under the act could be used for buildings, lands, pensions, or gratuities, and also that no agent of the Children's Bureau could enter any house over objection of the owner.

This measure was referred to the Committee on Interstate and Foreign Commerce of the House, and will be before the second session of the Seventieth Congress when it convenes next December.

Indian Health Needs—Sanitarians have long recognized the fact that the health of the Indians is thoroughly bad compared with that of the general population. The fact has been confirmed and emphasized in an impartial report on the problem of Indian Administration which has been recently issued by the Institute for Government Research of Washington, D. C. as the result of an extensive survey made at the request of Dr. Hubert Work, Secretary of the Interior.

In this report of some 870 pages, 155 pages are devoted directly to the health of the Indians and the medical and sanitary activities of the Indian Service. Appropriations for health are stated to have been inadequate and the personnel on this work insufficient, underpaid, un-

LAW AND LEGISLATION

JAMES A. TOBEY, LL.B., DR. P.H.

A Plan for Federal Child Welfare Extension—The original Sheppard-Towner Law, or, more properly, the Federal Maternity and Infancy Act, was passed on November 23, 1921, to take effect for a 5-year period ending June 30, 1927. Near the end of this period, Congress was importuned to continue the operation of the act for several years and after considerable wrangling agreed to a 2-year extension, but with the understanding that the law would positively cease on June 30, 1929. Both sides agreed to this.

Indian Health Needs—Sanitarians have long recognized the fact that the health of the Indians is thoroughly bad compared with that of the general population. The fact has been confirmed and emphasized in an impartial report on the problem of Indian Administration which has been recently issued by the Institute for Government Research of Washington, D. C. as the result of an extensive survey made at the request of Dr. Hubert Work, Secretary of the Interior.

In this report of some 870 pages, 155 pages are devoted directly to the health of the Indians and the medical and sanitary activities of the Indian Service. Appropriations for health are stated to have been inadequate and the personnel on this work insufficient, underpaid, un-

sirable, if not essential, in the modern restricted field of the barber, in the opinion of Dr. Arnold H. Kegel, Commissioner of Health of Chicago, author of this article. He tells us that upward of 50 ordinances for the control of barber shops and similar personal service establishments have been passed by the leading municipalities of the United States during the past decade.

General cleanliness of shops and attendants, washing of hands before serving each customer, prohibition of the use of common towels and other common articles, sterilization of utensils after each use, prohibition of practice by or on diseased persons, licensing of operators, and posting of the rules, are some of the important provisions of ordinances or regulations concerned with barber shops.

These are good principles, but how ardently are they enforced? Anyone who uses a barber shop knows the answer. In Chicago each shop was inspected once a year and many violations were found. As Dr. Kegel says, however, the progressive barber realizes that compliance with such laws is to his advantage and will increase his trade.

Recent Court Decisions on Health—In Alabama a municipality installed a sanitary toilet on private property where the owner had failed to obey an ordinance requiring such installation. Although the city failed to comply with the statutory requirements for getting a lien on the property, the State Supreme Court held the owner liable for the expense on a contract action. *Town of Leeds v. Cason*, 116 So. 519.

In Illinois it has been held that a registrar of vital statistics cannot refuse to accept and file a valid birth certificate, because the registrar's duties are purely ministerial. *People v. Heckard*, 244 Ill. App. 112.

Lapse of time does not establish a right to maintain a public nuisance, in

this case the pollution of a water course, according to a Texas decision. *City of Corsicana v. King*, 3 S. W. (2d) 857.

An employe injured by an occupational disease, in this instance benzol poisoning, cannot recover under the workmen's compensation act of the State of Washington. *Seattle Can Co. v. Dept. of Labor and Industries*, 265 Pac. 739. In Minnesota, on the other hand, chemical poisoning of a physician's assistant while eating his lunch near the office in order to be able to answer telephone calls was an injury under the workmen's compensation act of that state. *Krause v. Swartwood*, 218 N. W. 555.

A city garbage ordinance has been upheld in California. *Ex parte Santos*, 264 Pac. 281.

Tuberculosis Legislation—A comprehensive manual of tuberculosis legislation has recently been published by the National Tuberculosis Association of New York. This manual is designed for sanitarians, attorneys, legislators, and others who are interested in drafting or altering state laws and regulations on tuberculosis. It gives an outline of a state legislative program against this disease and analyzes and discusses every item in detail. There are also a general consideration of tuberculosis and the law, with notes on law making, and an index to all the existing state laws on tuberculosis. Copies of this manual may be obtained at a cost of 50 cents through the book service of the A.P.H.A.

Miscellaneous Items—Standards for clinical thermometers have been fixed by the Commercial Standards Unit of the U. S. Bureau of Standards and will become effective on October 1, 1928.

Cartons for packing butter are favored by health officials, according to the U. S. Department of Agriculture, which has recently conducted a survey of this subject in 117 cities.

BOOKS AND REPORTS

Health Essentials—By *J. Mace Andrews, Ph.D., A. K. Aldinger, M.D., and I. H. Goldberger, M.D.* Boston: Ginn, 1928. 481 pp. Price, \$1.72.

The authors consider the high schools as potent agencies in shaping public opinion and determining the progress of the nation. They hold that only a small percentage of high school students will go on to institutions of higher learning, while the large majority will end their formal education either before or at the time of graduation. The book is, therefore, designed especially for this class of students. Personal hygiene is placed first, with home hygiene as the second objective, and community hygiene the third; and since those in the high schools are facing the problem of choosing their life work, industrial hygiene is given due consideration, especially in regard to the health advantages or hazards involved.

The titles of the chapters have been selected with the object of being attractive. Health is held out as the foundation upon which success and happiness depend and not merely as an object in itself. Emphasis is laid on the prevention of disease and the building up of a virile personality. Introspection is to be avoided.

These ideas, taken largely from the preface, have in our judgment been successfully carried out. The text is enlivened by the life stories of prominent people, some of whom have succeeded in converting a childhood marked by ill health into an adult life of abounding vigor. Every chapter ends with questions for informal discussion in class and at home.

We have failed to find any topic undiscussed which boys and girls of the

age indicated should understand, and the information given is not only sound but clearly put. The illustrations are plentiful, good, and up-to-date.

Only a few points calling for criticism have come to our attention. The vitamin table, page 136, dates back to 1921, though much more recent tables are available. On page 139, under the heading "Food Poisoning," botulism only is considered. The discussion of infected foods in Chapter XX, to which we are referred for further information, is incomplete, and contains some statements which are erroneous, as for example, that Walter Reed discovered the "cause" of yellow fever, and Pasteur "a treatment for rabies." This latter mistake is already too common and should not be taught in schools. Harvey published his discovery of the circulation of the blood in 1619, and it is described in his notes dated 1615.

On the whole the book is well written and its make-up excellent. It can be safely recommended as a text for the class of students for whom it is designed.

M. P. RAVENEL

Industrial Nursing—(*Reissue*) By *Florence Swift Wright, R.N.* New York: Macmillan, 1928. 179 pp. Price, \$1.50.

To the nurse in an industrial position we recommend this reprint of Florence S. Wright's book because of the completeness of her understanding of the worker, the managing personnel and the employer; also because her views are applicable today—after ten years—and probably will be equally so for the next decade.

The nurse who has all the necessary credentials of preparation and person-

M. P. RAVENEL

Industrial Nursing—(*Reissue*) By *Florence Swift Wright, R.N.* New York: Macmillan, 1928. 179 pp. Price, \$1.50.

To the nurse in an industrial position we recommend this reprint of Florence S. Wright's book because of the completeness of her understanding of the worker, the managing personnel and the employer; also because her views are applicable today—after ten years—and probably will be equally so for the next decade.

The nurse who has all the necessary credentials of preparation and person-

who thinks he is free from disease. This will possibly help to a greater degree than we imagine, to eradicate cancer from the earth. It will also allay the fears of many people for whom the disease of cancer has such a dread.

We would highly recommend the book to anyone interested in the subject, both for private information and also as a basis for material for popular lectures.

WALLACE CRAWFORD

La Vaccination Préventive Contre la Tuberculose par le "BCG"—

By A. Calmette, Sous-Directeur de l'Institut Pasteur, Avec la Collaboration de C. Guérin, A. Boquet et L. Nègre. Paris: Masson et cie, 1927. 233 pp. Price, 22 Fr.

All bacteriologists, and especially those interested in immunization against tuberculosis, have followed carefully the work of Calmette and his associates, which began in 1903. The publications have appeared in various journals, though chiefly in the *Annales de l'Institut Pasteur*. It is a matter of great convenience to have all of this material now collected into one volume.

The book is divided into four parts, the first of which gives a good review of the attempts at vaccination from the time of the discovery of the tubercle bacillus. It is a matter of congratulation that American work is clearly recognized, and that Trudeau is given credit for his pioneer contributions.

The second part is devoted to the experimental studies on animals with the Calmette-Guérin vaccine, now universally known as "BCG." This section includes also the experiments of Wilbert on the vaccination of apes in the tropics.

The third part gives the history of BCG, its modification by growth on bile, begun in 1906, and its present preparation for use. The synthetic medium of Sauton is described. Biochemical, physiological, and histological studies are also included, the latter illus-

trated by plates made from microphotographs.

The fourth part is in some ways the most interesting, as it treats of vaccination of infants since 1921, and the results obtained. At the end of this section the forms used in connection with the statistical studies are reproduced.

The whole constitutes the record of a monumental piece of work, which has occupied a quarter of a century, and which has commanded the respect and attention of all scientific men. While the results obtained by the author and his coworkers have not been duplicated in other countries, and some criticism has been made of his controls, his work must always stand foremost in this line of endeavor. Concerning, as it does, the control of one of the chief scourges of mankind, the book should be read by physicians as well as bacteriologists.

The printing is excellent, and needless to say, it is written in the clear style characteristic of its senior author.

M. P. RAVENEL

Modern Aspects of the Diagnosis, Classification, and Treatment of Tuberculosis—*By J. A. Myers, with Introduction by David A. Stewart. Baltimore: Williams & Wilkins, 1927. 271 pp. Price, \$5.50.*

The purpose of this volume is to present the facts regarding tuberculosis in a simple manner "in the hope that it will stimulate among students and physicians a new interest in the study of this disease," serving both as an inspiration and as a source of real knowledge. The author has achieved his goal in this book for it is a very concise account of tuberculosis in all of its aspects.

The subject is divided into three parts: general consideration; diagnosis and classification; healing, prognosis and prevention. The book is certainly not written in too great detail, in fact the major criticism which the reviewer has to offer is that there appears to be a

who thinks he is free from disease. This will possibly help to a greater degree than we imagine, to eradicate cancer from the earth. It will also allay the fears of many people for whom the disease of cancer has such a dread.

We would highly recommend the book to anyone interested in the subject, both for private information and also as a basis for material for popular lectures.

M. P. RAVENEL

Modern Aspects of the Diagnosis, Classification, and Treatment of Tuberculosis—*By J. A. Myers, with Introduction by David A. Stewart. Baltimore: Williams & Wilkins, 1927. 271 pp. Price, \$5.50.*

The purpose of this volume is to present the facts regarding tuberculosis in a simple manner "in the hope that it will stimulate among students and physicians a new interest in the study of this disease," serving both as an inspiration and as a source of real knowledge. The author has achieved his goal in this book for it is a very concise account of tuberculosis in all of its aspects.

The subject is divided into three parts: general consideration; diagnosis and classification; healing, prognosis and prevention. The book is certainly not written in too great detail, in fact the major criticism which the reviewer has to offer is that there appears to be a

mislead the uninformed. He says for example: "Sugar is undermining the nation's health." He condemns the great popularity of spinach, largely on account of the oxalic acid it contains, but partly for its high residue, and would add a Twentieth Amendment to the Federal Constitution prohibiting its use. On the next page he praises "lettuce as the greatest vegetable food given to humanity," though it is mentioned in several other places as being a high residue food. He makes no distinction between the colored lettuce and the bleached in regard to vitamin content.

On the whole, the book can be commended to laymen who do not care to go deeply into the subject. The printing and makeup are excellent and only a few mistakes have been detected. On page 12, the name of Dr. Graham Lusk is misspelled. Many chapters end with useful and appropriate axioms.

M. P. RAVENEL

Michigan Handbook of Hospital Law—By Dorothy Ketcham. Dearborn: Michigan Hospital Association, 1928. 237 pp. Price, \$2.00.

Physicians, sanitarians, and hospital executives in Michigan ought to find this little handbook indispensable. It should also serve as a guidebook for the preparation of similar reference books in other states.

This handbook summarizes the legal requirements affecting hospitals in Michigan. It has a convenient alphabetical arrangement of subjects, with numerous annotations to legislation, court decisions, and works of reference. The appendices contain a directory of hospitals and sanatoriums in the state, a list of agencies interested in hospitals, the state medical practice act, a bibliography (which is none too modern in some respects), a table of cases and much other useful information. There is a good index, and the book is well printed.

The idea is excellent and it is, in gen-

eral, well executed. This handbook is worth emulation elsewhere.

JAMES A. TOBEY

Personal Hygiene Applied (3d ed.)—By Jesse Feiring Williams, M.D., Teachers College, Columbia University. Philadelphia: Saunders, 1928. 458 pp. \$2.00 net.

This new edition of a well-known book is welcome. The first edition appeared 6 years ago. A book which has gone through 3 editions with 12 printings has made its place. The new edition brings the material up to date, with an increase of about 40 pages. A number of new illustrations have been inserted.

Not only the text, but the makeup of the book is up to the standard which was set by former editions. The reviewer continues to believe that it is the best book in its field.

M. P. RAVENEL

Group Clinics. A Study of Organized Medical Practice—By Walter C. Klotz, M.D. New York. 1927. 32 pp.

Health Services in Clinics—By Anna Mann Richardson, M.D. New York. 1927. 83 pp.

These two pamphlets are published by the Committee on Dispensary Development of the United Hospital Fund of New York.

Dr. Klotz takes up the origin of group clinics, and analyzes a few clinics as to their development and organization, physical construction and equipment, routine, services rendered, scope of practice, financial regulation and affiliations with hospitals and social service agencies.

In Dr. Richardson's pamphlet a brief résumé of the services rendered to children and adults at the several New York City health centers is given. This pamphlet can be of invaluable aid to the medical director and social service worker interested in obtaining information about practical procedure in successful health centers.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

New Jersey—Bound in cloth covers, printed in good readable type, and containing both a table of contents at the front and an index at the back, this 50th annual report of 277 pages for the year ending June 30, 1927, records several advances in public health work. A state-wide movement to increase diphtheria immunizations was undertaken; a method for direct microscopic examination of milk for practical field use was developed; the continuous child hygiene program under state supervision was adopted by several new communities; the venereal disease control program was extended; and a successful school for employed health workers was conducted jointly by the state university and the Department of Health.

The outstanding accomplishment pertaining to milk control was the enactment of Chapter 233 of the laws of 1927 providing that no person shall purchase, distribute or sell for human consumption, any milk or cream which has not been pasteurized, excepting that produced by cows which have successfully passed a tuberculin test given the year of the sale of such milk or cream.

The child hygiene demonstrations are carried on by nurses in the various communities, usually for one year. At the end of the period, the community is asked to take over the salary of the nurse. There are 90 nurses under state supervision, 73 of whom are paid by the municipalities, 9 by the state, and the remainder out of state and municipal funds. The examination of preschool children to detect remedial defects before the child enters school has been emphasized in the baby-keep-well stations.

Work has been conducted in continuation schools in 3 districts. The girls are taught the principles of child hygiene

and health prevention and the nurses have been able to secure corrections of defects discovered among the girls themselves following physical examinations. During the year, the teaching of preventive measures to the student teachers in the normal schools has been extended so that all 5 schools are now covered.

The estimated population for 1926 was 3,570,159. A birth rate of 20.27, a death rate of 12.4, and an infant mortality rate of 70.3 (122.1 for colored) are recorded. Important statistical data are tabulated for long periods beginning with 1879, and several good charts add interest to the report.

Otero County, Colo.—A mimeographed report for 1927 shows that this county of 26,513 persons, 6,711 of whom were school children, had the benefit of full-time health service at a reasonable cost. There are 6 incorporated towns in the irrigated district, comprising 79,615 acres, the remaining area being utilized as dry farming and grazing land. During the year there were 570 births and 355 deaths, the chief causes of death being heart disease (57), pneumonia (38), gastroenteritis (32), premature births (31), cancer (28), and tuberculosis (25). During 1926 and 1927, 2,847 complete toxin-antitoxin immunizations were given, and it is noteworthy that last year there were only 2 diphtheria cases and 1 death reported. During the 2-year period, 1,791 smallpox vaccinations and 780 typhoid vaccinations were performed.

Macon City and Bibb County, Ga.—The 1927 report of the joint city and county board of health is well printed, contains a classified financial statement showing an expenditure of \$42,000 for

a population of 82,299 (37,188 colored), several good charts and statistical tables. Of unusual interest is the progress in sewer extensions reported. Following 37 deaths from diarrhea and enteritis, the attention of the mayor and council was directed to several congested districts affected. These were surveyed, with the result that increased appropriations were made to place sewer connections within reach of several hundred houses, the remaining districts being provided with sanitary pit privies (1,339).

Typhoid fever cases numbered 28 in 1927 as compared with 104 the previous year. Infant mortality dropped from 119.1 to 89.4, while the general death rate decreased from 16.6 per 1,000 population to 13.4. The Health Officer's report concludes with recommendations for further extension of health services along modern lines.

Rockford, Ill.—Special features of this 1927 report include an organization chart showing essential health activities, a unique chart showing office arrangements in the department, a financial statement, good statistical graphs and tables. "The extensive use of charts, maps, and diagrams has continued to be of especial value also as executed by each bureau, and has assisted in bringing the message of health to the public at times of conventions, exhibits, and addresses before clubs and parent-teacher associations."

It is noteworthy that 98.5 per cent of the milk supply in this city of 81,800 population, is pasteurized. Over 76 per cent of the births in 1927 occurred in 3 local hospitals. An infant mortality rate of 62.35 (50.96 resident), a general death rate of 9.97 (8.59 corrected for residence), and a resident birth rate of 16.66 are reported.

Pennsylvania Dairy and Milk Inspectors—Milk inspectors and health officers will find the 4th annual report

of the Pennsylvania Association (211 pages) of considerable interest. Formal addresses and committee reports cover a wide range of study and observation, including programs, legislation, education, laboratory and field investigations, and results. Increasing emphasis is being given to the importance of milk control in small communities, to the value of laboratory as well as field supervision, and to the importance of pasteurization, scientifically controlled. A few colleges have developed practical summer courses for training milk inspectors and laboratory workers.

Missouri Public Health Association—A mimeographed copy of the proceedings of the 3rd annual meeting of this state association held in coöperation with the State Board of Health and the International Health Board, contains the instructive papers presented at the 4-day session. The topics include epidemiology, laboratory procedures, tuberculosis and venereal disease control, rabies, mental hygiene, nursing, record keeping, publicity, child hygiene, public safety, sanitation, and community organization. . .

Cuyahoga Falls, O.—This city of 14,400 population covers an area of 9 square miles and has 72.48 miles of sanitary sewers and 74.35 miles of water mains. The school enrollment totals 3,421. A birth rate of 16.6, a death rate of 8.7, a tuberculosis death rate of 34.7 (per 100,000), and an infant mortality rate of 41.8 are recorded. The average age at death was 52 years in 1927. The report lists population and mortality figures of interest for 17 Ohio cities of similar population to that of this city. There were 9,701 nursing visits made during the year, of which 1,547 were to school children and 823 to tuberculosis patients. Scarlet fever was the outstanding disease of the year, with 104 cases and 1 death. Weekly laboratory anal-

yses are made of the milk and water supplies, the average bacteria count of the milk for the year being 20,400.

Kenmore, O.—Kenmore covers approximately 5 square miles and has a population of 20,467, with a school enrollment of 4,161. A birth rate of 18.1, a death rate of 4.6, a tuberculosis rate of 30.9 (per 100,000), and an infant mortality rate of 48.6 are recorded. There were no deaths from diphtheria, measles or scarlet fever, and but 1 death (30 cases), from whooping cough during the year. Nursing visits totaled 12,531—2,187 being to school children, and 1,998 to tuberculosis patients. "The physicians have materially assisted the Department of Health in the control of communicable diseases, and the board of health wishes to extend to the physicians of Kenmore their appreciation for this coöperation, as well as their prompt and complete reporting of the communicable diseases."

Mount McGregor Sanatorium—During the year 1927, 467 patients were admitted to this sanatorium of the Metropolitan Life Insurance Company, from the United States and Canada, and 430 were discharged. Of those admitted, 200 were tuberculous. A classification of types of cases admitted shows that 6.5

per cent were suspects, 38.5 per cent in the incipient stage, 34 per cent moderately advanced, 19.5 per cent far advanced, and 1.5 per cent non-pulmonary. The results of treatment in the discharged cases for the year show that 15 per cent were arrested, 68 per cent quiescent and improved, 10 per cent unimproved, and 7 per cent dead. The report contains other statistical data of considerable interest from the standpoint of diagnosis and treatment.

Pontiac, Mich.—The 4th annual report of the manager of Pontiac shows that approximately 10.5 square miles of area were annexed to the city in 1927, more than doubling the area and increasing the population by 4,655. The Public Health Department report shows a general death rate of 9.6, a birth rate of 24.5, and an infant mortality rate of 62.6. Of the total births, 32.4 per cent occurred in hospitals.

During the year, 4,672 toxin-antitoxin treatments and 1,176 Schick tests were given by the medical division of the public schools and the health department. Nursing visits to prenatal cases numbered 484, to infants 3,220, to pre-school children 7,649, and inspections of baby boarding houses 66, in addition to other work. Of the total milk supply, 95 per cent is pasteurized.

BOOKS RECEIVED

CHILD BIRTH. An Outline of Its Essential Features and the Art of Its Management. By Wm. G. Lee. Chicago: University of Chicago Press, 1928. 300 pp. Price, \$3.00.

PHYSIOLOGY AND BIOCHEMISTRY OF BACTERIA. Vol. I. By R. E. Buchanan, Ph. D. and Ellis I. Fulmer, Ph. D. Baltimore: Williams and Wilkins, 1928. 516 pp. Price, \$7.50.

PUBLICITY FOR SOCIAL WORK. By Mary Swain Routzahn and Evert G. Routzahn. New York: Russell Sage Foundation, 1928. 392 pp. Price, \$3.00.

THE PROBLEM OF INDIAN ADMINISTRATION. Report of survey made at request of Hon. Hubert Work, Secretary of the Interior, Washington: Institute for Government Research, 1928. 872 pp. \$5.00.

NURSES, PATIENTS AND POCKETBOOKS. Report of a Study of the Economics of Nursing Conducted by the Committee on the Grading of Nursing Schools. By May Ayres Burgess, Director. New York: Committee on the Grading of Nursing Schools, 1928. 618 pp. Price, \$2.00.

NUTRITION. Walter H. Eddy. Baltimore: Williams & Wilkins, 1928. 237 pp. Price \$2.50.

EAT, DRINK AND BE HEALTHY. An Outline of Rational Dietetics. By Clarence W. Lieb. New York: John Day, 1928. 180 pp. Price, \$1.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Light Therapy in Clinics—British health authorities are urged to include artificial sunlight therapy in child hygiene clinics for rickets, skin diseases, and non-pulmonary tuberculosis.

BANKS, H. S. Artificial Sunlight Treatment in Public Health Work. *Pub. Health*, 41:9 (June), 1928.

Cancer Control—The author objects to "cancer week as in America" and suggests instead a sustained educational program. Being British, he does not know that doing things by weeks is our besetting national vice.

BELL, W. B. The Prevention of Cancer. *J. State Med.*, 36:6 (June), 1928.

Dental Caries in Childhood—The importance of mineral salts in preventing dental caries in children is indicated by the recorded experience with diabetic children in which a diet rich in salts arrested the caries. An important contribution for hygienists.

BOYD, J. D., and DRAIN, C. L. The Arrest of Dental Caries in Childhood. *J. A. M. A.*, 23:23 (June 9), 1928.

College Student Hygiene—Self supporting students made more frequent dispensary visits and spent more time in the infirmary than did independent students at Oberlin University.

BRADSHAW, R. W. Health of the Self Supporting College Student. *J. A. M. A.*, 90:22 (June 2), 1928.

The Science of Epidemiology—This paper is a discussion of the history and practice of epidemiology addressed to the educated laity. Very well done; useful as an example for others who write.

CHAPIN, C. V. The Science of Epidemic Diseases. *Scienc. Monthly* (June), 1928.

Electrophoresis of Diphtheria Bacilli—This is a series of papers discussing and describing the method of determining virulence by electrical reactions. The authors report the method to be simple and, in general, to give reliable results as checked against guinea pigs.

FALK, I. S., et al. Electrophoresis of Diphtheria Bacilli. *J. Bact.*, 15:6 (June), 1928.

Sex Education—The moral, social, and biologic aspects of sex are dealt with fearlessly in this stimulating paper. The author concludes that we could be rid of the venereal diseases in a single generation by utilizing fully all the means of education at our command.

HILL, T. W. Sex Education as a Public Health Problem. *Med. Off.*, 39:20 (May 19), 1928.

Rheumatism Control—A hopeful summary of the problem, emphasizing the importance of personal hygiene and environmental conditions in childhood.

NEWMAN, G. The Control of Rheumatism. *Med. Off.*, 39:20 (May 19), 1928.

Antirachitic Factor in Human Milk—Human milk contains no antirachitic factor for rats, whereas cow's milk does possess rickets-healing substance. This phenomenon is not due to a higher percentage of calcium and phosphorus in the latter.

OUTHOUSE, J., et al. Human Milk Studies. *J. Biol. Chem.*, 78:1 (June), 1928.

Rabies Prophylaxis—An article emphasizing the importance of cauterizing dog bites with fuming nitric acid and the advantages of the Semple prophylactic injections.

ROSENAU, M. J. Rabies. *Northeast J. Med.*, 108:15 (May 31), 1928.

Diphtheria Immunization Procedures—Directions for using the Schick test outfits and toxin-antitoxin mixture supplied by the Massachusetts health department.

SCAMMAN, C. L. Active Immunization against Diphtheria. *Northeast J. Med.*, 198:16 (June 7), 1928.

Brucella Abortus Infections—This paper is a report of seven cases of *B. abortus* infection in man and describes the widely varied clinical symptoms observed. It confirms earlier reports of such infections.

SENSENBICK, R. L., and GIORDANO, A. S. *Brucella Abortus* Infection in Man. *J. A. M. A.*, 90:22 (June 2), 1928.

Etiology of Rheumatic Fever—The author offers *streptococcus cardio-arthritis*, a new species with distinguishing cultural and serologic characteristics, as the cause of the condition. Antisera are found to have therapeutic value, and the antigen prepared from the organisms stimulates active immunity.

SMALL, J. C. Rheumatic Fever. *Am. J. Med. Sci.*, 175:5 (May), 1928.

Spray Painting Hazards—This summary of two studies of spray painting emphasizes the danger of benzol poisoning when this solvent is used; the use of benzol substitutes; the periodic examination of sprayers. The lead and silicosis hazards in spraying vitreous enamels is also covered.

SMYTH, H. F., and SMYTH, H. F., Jr. Spray Painting Hazards as Determined by the Pennsylvania and the National Safety Council Surveys. *J. Indust. Hyg.*, 10:6 (June), 1928.

Serum Sensitization—Serum reactions occurred almost as frequently among persons who had previously never received horse serum as among those who had. In a small series of cases it was found that toxin-antitoxin did not sensitize the patient. That such sensitization occurs is doubted by the author.

SPICER, S. The Effect of Previous Administration of Antitoxin and Toxin-Antitoxin on Serum Reaction. *J. A. M. A.*, 90:22 (June 2), 1928.

Educational Standards for Sanitarians—In a few of the closing paragraphs of his inaugural address, the president of the A. M. A. appeals for an adequately trained public health personnel.

THAYER, W. S. Inaugural Address as President of the A. M. A., *J. A. M. A.*, 90:24 (June 16), 1928.

Bathing Beach Pollution—A bacteriologic study of the waters at public bathing beaches about New Haven Harbor showed that the water was so polluted with New Haven sewage that the beaches were unfit for bathing. Similar studies might well be made of similar conditions near other large cities.

WINSLOW, C.-E. A., and MOXON, D. Bacterial Pollution of Bathing Beach Waters in New Haven Harbor. *Am. J. Hyg.*, 8:3 (May), 1928.

NEWS FROM THE FIELD

DR. FORGE FULL-TIME COUNTY HEALTH OFFICER

DR. F. W. Forge has been appointed full-time Health Officer of Charves County, N. M. Pending the appointment of Dr. Forge, the health work in the county was directed by Dr. W. W. Phillips who was carrying on this public work along with his private practice, but found it an overburdening task to do both pieces of work.

HERMAN N. BIGGS MEMORIAL FUND

THE Herman N. Biggs Memorial Fund recently gave \$55,000 to New York University and Bellevue Medical College to establish a Herman N. Biggs professorship in preventive medicine.

OHIO PUBLIC HEALTH ASSOCIATION HEALTH COURSE

DR. R. G. Paterson, executive secretary of the Ohio Public Health Association will conduct a course in public health in connection with the Ohio Welfare Conference in Columbus, O., October 8-10, headquarters at the Deshler-Wallick Hotel.

Ten study courses are to be given at the conference, and each course will consist of 5 sessions. Assisting Dr. Paterson will be C. L. Brownell of Ohio State Department of Education; Howard W. Green, Cleveland Health Council; and Bleeker Marquette, Cincinnati Public Health Federation.

OHIO TUBERCULOSIS SOCIETY CHANGES NAME

THE Ohio Society for the Prevention and Cure of Tuberculosis has changed its name to the Ohio Public Health Association and will extend its activities to include other phases of public health work. Committees are to be established to deal with tuberculosis,

public health nursing, hospitals, clinics, social hygiene, better milk, child hygiene, heart disease, industrial hygiene, cancer, mental hygiene, mouth hygiene, and periodic physical examinations. The 27th Annual Meeting of the Ohio Public Health Association was held recently when the plan of reorganization was submitted by Dr. Robert H. Bishop, Jr., president.

DR.P.H. FROM FOREIGN COUNTRIES

RECIPIENTS of the degree of doctor of public health and the certificate in public health given by Johns Hopkins University at its 1928 commencement included candidates from Spain, Turkey, Jamaica, Hungary, Japan, China, Columbia, India, Czechoslovakia, Bulgaria, Jugo-Slavia, Mexico, Chili, Germany and Honduras.

An anonymous gift of \$1,000,000 was made to the university and a gift of \$500,000 was made to complete the endowment of the William H. Welch Medical Library. A gift of \$100,000 was also made to the Wilmer Eye Clinic.

HOLLAND INSTITUTE OF THERMOLOGY

TO teach the American home-owners in a practical way the science of heating and ventilating their homes in relation to health, the Holland Institute of Thermology has been established. The institute has been created by A. H. Landwehr, president of the Holland Furnace Company of Holland, Mich. It is the hope of the promoter of the institute to make a contribution to health conditions by perfecting ventilation in the home. A research engineer will direct the tests and investigations which will be made public from time to time.

The investigations will attempt to determine how many diseases result from the improper or inadequate humidify-

ing of homes; how the seasonal occurrence of certain respiratory diseases can be modified or reduced by control of the humidity, temperature and circulation of the air in dwellings; the national economic loss due to soot and the methods available to prevent it. There will be fuel studies as related to the national fuel reserves; a medical analysis of conditioning the air so that atmosphere in the home will contribute to the health, efficiency and comfort of the family; a test for the number of air changes required in each room every hour to keep the atmosphere healthy and free from noxious germs; studies of methods of sterilizing air to minimize the circulation of disease-ridden air homes, and to ascertain the heating costs of the average home-owner.

JOHNS HOPKINS COURSE FOR PUBLIC HEALTH OFFICERS

A COURSE for the additional training of physicians who are engaged or who plan to become engaged in public health work will be given at Johns Hopkins University during the spring trimester, March 11-June 1, 1929. The course will be offered if not less than 10 students register for it by February 11, 1929. Candidates eligible to take the course must be graduates in medicine or have had other special training specified in the requirements. At the conclusion of the course a certificate of attendance will be awarded.

MATERNITY WELFARE IN LATIN AMERICA

AMONG the resolutions passed by the committee on social problems and hygiene of the Sixth International American Conference held in Habana from January 16 to February 22, 1928, was one recommending that every American country should have a corps of visiting public health nurses.

Another resolution recommended the enactment of laws providing for compulsory vacations for expectant mothers,

whether in public or in private service, for 40 days before and 40 days after confinement, with the payment of full salary.

THE CAIRO CONGRESS

ANNOUNCEMENT has been made of The Centenary celebration of the Faculty of Medicine, Cairo, and the International Congress of Tropical Medicine and Hygiene, to be held under the patronage of His Majesty, King Fouad I, December 15 to 22, 1928. The work of the Congress will be carried out by the following sections: tropical medicine, surgery, ophthalmology, hygiene and sanitation, parasitology, and pathology and bacteriology.

CALIFORNIA MAKES TWO ADDITIONAL DISEASES REPORTABLE

TULAREMIA and coccidioidal granuloma have been made reportable diseases by the California State Board of Public Health, according to a recent announcement from Walter M. Dickie, M.D., Director.

Health officers have been requested to notify physicians in their respective territories under their jurisdiction in order that cases of these diseases will be reported promptly.

MICHIGAN MAKING BREAST FEEDING SURVEYS

BREAST feeding surveys are being made in five counties in Michigan, including Menominee, Houghton, Arenac, Montcalm and Crawford.

MATERNAL MORTALITY DECREASE IN RURAL NEW YORK

IN rural New York there was a decrease of 26 per cent in the maternal mortality rate for the period 1921-1925 from the rate for 1915-1920. This decrease is considered as possibly due to the increased use of hospitals for confinement purposes by rural mothers.

FINDINGS IN COST OF MEDICAL CARE

THE demand for medical services, their supply and distribution are subjects of a preliminary survey being made by the Committee on the Cost of Medical Care, which has its 5-year program well under way.

According to an announcement recently made by the chairman of the committee there are now 1,000,000 persons engaged on a whole-time basis in curing and preventing diseases. Although \$5,000,000,000 are invested in hospitals and other equipment, many people of the United States are not receiving adequate medical service at costs within their means. It is found that the high costs are due often to the many separate bills, not only the physicians' fees. Too, physicians as a group are not earning adequate incomes considering the cost of their years of training and their overhead expenses, and many do not have access to hospitals and other facilities for scientific work. It has also been found that nurses and dentists are not receiving satisfactory returns for their services. It is the purpose of the committee to investigate the fundamental causes of the existing situations, and to make recommendations for the remedies.

In addition to the cost to the people of hospital care, nursing, dentistry, drugs, physiotherapy, surgery, and other medical services, the committee will follow the preliminary survey with a study of the problems involved in the prevention and cure of disease.

Another group of studies will be an analysis of industrial medical services and other organized facilities now serving particular groups of the population.

It has been estimated that illness costs

the people of the United States more than \$5,000,000,000 a year.

The committee's program is being supported by the Carnegie Corporation, Milbank Memorial Fund, Russell Sage Foundation and the Twentieth Century Fund. The American Medical Association, the U. S. Public Health Service and the Metropolitan Life Insurance Company will coöperate with the committee.

Officers of the committee organized in May, 1927, are: Ray Lyman Wilbur, M.D., President Stanford University, Chairman; C.-E. A. Winslow, Dr.P.H., School of Medicine Yale University, Vice-chairman; Chellis A. Austin, Seaboard National Bank, Treasurer; and Harry H. Moore, director of study.

HEALTH OFFICERS TO MEET IN OCTOBER

THE annual meeting of California health officers will be held, as usual, in conjunction with the convention of the League of California Municipalities in San Bernardino October 9 to 13, 1928. Preparations for the program are now under way and the 1928 meeting gives promise of being the most successful ever held.

UNIVERSITY OF TORONTO'S M.D. DEGREE

THE proposal, sponsored for some time past by Dr. Herbert Bruce, has finally been accepted by the Board of Governors of the University of Toronto with the announcement on June 1 that the university has fallen into line with many other universities in different parts of the world and has decided to grant the degree of Doctor of Medicine to all students qualifying in the 6th year course. This will take the place of the degree of Bachelor of Medicine, which was the only award up till the present.

PERSONALS

- W. S. BIZZELL, for several years sanitary engineer with the Fort Worth, Tex., City Health Department, has been appointed supervisor of public utilities for the City of Coleman, Tex.
- DR. T. A. CALLAHAN has been appointed full-time County Health Officer for Hartford County, Md.
- DR. PORTER J. CRAWFORD, formerly secretary of the Miami, O., County Public Health League and Health Commissioner of Troy and Miami Counties, O., sailed for Brazil, July 1, as a member of the Rockefeller Foundation. He will assist the Brazilian Government in the establishment of local health units in Northern Brazil and in the program of prevention of yellow fever.
- DR. EDGAR R. HIATT has resigned as health commissioner of the City of Logan and Hocking County, O., to become health commissioner of the city of Troy and Miami County. He succeeds Dr. Porter J. Crawford.
- DR. F. D'HERELLE of Paris has been appointed professor of bacteriology in the School of Medicine, Yale University. Dr. d'Herelle is best known for his development of the subject of bacteriophagy, although he has made other contributions to the subject of bacteriology. Dr. d'Herelle is a native of Montreal, Can., and has had extensive experience in foreign fields.
- DR. E. MURPHY HOWARD, JR., Harlan, Ky., and Dr. Lawrence T. Minish, Frankfort, Ky., have been appointed to the Kentucky State Board of Health for a period of 4 years by Governor Sampson. They will succeed Dr. Joseph E. Wells of Cynthiana and Dr. James W. Kincaid of Catlettsburg.
- DR. S. ROWLAND HILL has been reappointed City Health Officer of Lansing, Mich.
- GRACE LUBIN, PH.D., has been appointed director of the serologic work of the laboratories of the Michigan State Board of Health at Lansing. Dr. Lubin succeeds Reuben L. Kan, Sc.D., who goes to Ann Arbor as director of the laboratory of the University Hospital.
- DR. JOHN S. FULTON, who has been with the Maryland State Health Department since 1896 has resigned as director and has been appointed director emeritus. Dr. Robert H. Riley, assistant director, has been appointed to succeed Dr. Fulton.
- DR. WILLIAM C. CAMP of Spencer, W. Va., has been appointed Health Officer of Roane County.
- OLLIE E. READ, head of the dairy husbandry division, Michigan State College of Agriculture, East Lansing, Mich., has been appointed chief of the Bureau of Dairy Industry, U. S. Department of Agriculture.
- DR. RAFFAELE LORINI, health officer of Coronado, Calif., for 27 years, has resigned. Dr. Charles W. Lane is acting City Health Officer of Coronado, pending the reorganization of the city Board of Health.
- DR. A. GRANT FLEMING has been appointed Director of the Department of Public Health and Preventive Medicine at McGill University, Montreal, Can.
- DR. CHANNING E. DAKIN has been appointed Health Commissioner of Mason City, Ia. to succeed the late Dr. Matthew J. Fitzpatrick.
- DR. ROBERT SEBASTIAN COWLES of Franklin, Tenn. has been appointed Health Officer of Greene County, Tenn.

Dialyzed ANTIRABIC VACCINE

RABIES VACCINE (CUMMING) consists of rabic brain tissue that has been dialyzed against running water until the infectivity of the virus is completely destroyed. The vaccine is incapable of causing rabies when injected into a susceptible animal, either hypodermically or intracranially. The intracranial test is applied to every lot manufactured.

The relative purity of the product is such that its use in human practice involves a minimum risk of toxic effect of any kind.

Moreover, with the highest attainable degree of safety in administration, Rabies Vaccine (Cumming) combines an exceptional protective efficiency. Given soon enough, and in connection with the proper treatment of the wound, its record in the 20,000 or more cases in which it has been used is one of practically uniform success.

Rabies Vaccine (Cumming) is sent on telegraphic order to any point in the United States or Canada, day or night. Orders may be addressed to our laboratories at Detroit or to any of our branches or distributing depots.

A Sickness Survey of Winchester, Mass.

Part I: General Mortality

HERBERT L. LOMBARD, M. D., M. P. H.; FELLOW A. P. H. A

Massachusetts Department of Public Health, Boston, Mass.

IN THE spring of 1927, the Massachusetts Department of Public Health conducted a morbidity study in the town of Winchester, Mass. This town, one of a group of cities and towns which comprise Metropolitan Boston, is about eight miles north of downtown Boston. Winchester is largely residential, although there are a few manufactories, industries, and small stores. The estimated population of the town in November, 1926, was 11,890. It has a 55-bed hospital, and a very active Visiting Nurse Association. The schools of Winchester are among the best in the state, and for a number of years they have used the physical examination records which comply with the standards as set forth by the State Departments of Education and of Public Health. The Board of Health is a most progressive one, and is doing a very satisfactory piece of work. There are 28 physicians living in Winchester, 14 of whom practice in the town.

METHOD OF APPROACH

The surveyors made a house-to-house canvass of the town and obtained from each person interviewed the following information concerning every member of the family: the name, address, and position in the family, the country of birth, the age, sex, whether or not the individual was a wage earner, the present illness and illnesses during the past year, the type of treatment secured, and the amount of time lost from work. For all individuals under 20 years of age, additional information was sought relative to diphtheria, chicken pox, German measles, mumps, scarlet fever, measles, and whooping cough. A history

NOTE: The results of the Winchester studies will be published in the JOURNAL in three parts. The second part dealing with the contagious diseases, and the third with the relation of physical defects to school absenteeism, will appear in the October issue.

of any of these diseases necessitated questions concerning the type of treatment and the year in which the disease occurred. An estimate was made of the economic status of the family, classifying all families in one of four groups: poor, moderate, comfortable, or wealthy.

If no member of the family was at home, blanks were left requesting that the desired information be forwarded, as the time allotted to the survey did not permit return visits. During one week of the survey, the practicing physicians in Winchester reported to the department the number of sick individuals whom they attended. This information, together with the records of the Winchester Visiting Nurse Association, was compared with the data collected by the investigators to check on the reliability of the survey. The death records were tabulated similarly to the morbidity records. A study of nursing and hospital facilities was made by consulting the records of the Winchester Visiting Nurse Association and those of the Winchester Hospital, as well as by the questionnaire method. The contagious disease records of the Winchester Board of Health were obtained to ascertain the number of diseases that were reported and the number hospitalized. The data contained on the physical record forms used in the Winchester schools was studied in relation to school absenteeism.

GENERAL DISCUSSION OF RESULTS

Records were obtained from 9,746 individuals. This comprised 82 per cent of the estimated population of the town at the time the survey was made. A census of the surveyed population is shown in Table I.

Winchester has an older population than the state. The proportion of foreign born population is less than that of the state as a whole, although the proportion of Irish and Italian is higher in Winchester than in Massachusetts as a whole. The sex ratio of Winchester differs materially from that of the state proper, since Winchester has 80.8 males for every 100 females, while Massachusetts has 96.3 males for every 100 females.

It is impossible to state mathematically the degree of reliability of the Winchester sample. The surveyed individuals were well distributed throughout the town, and in all probability furnish a very fair sample of the whole town. The accuracy of the answers given to the investigators varies considerably with the different questions. In the contagious disease part of the study the householder was asked specifically whether or not the individual members of the family had had the given diseases. The answers to these questions were largely correct, although there was some confusion between measles and German measles. The follow-up question regarding whether or not a

NOTE: Totals include individuals for whom one or more items regarding age, sex and nationality are not complete.

doctor had seen the sick child was not so accurately answered, as many householders evidently confused the call of the Board of Health with that of the practicing physician.

In the morbidity study, the question whether the individual had had any illness in the past year was asked, and the answer depended on what the person answering the question considered an illness. Some considered the slightest pain an illness, while others did not consider themselves sick unless they were confined to bed; consequently, the morbidity figures are more accurate in the more severe conditions than in the minor ailments. But, as the survey was primarily intended to ascertain the extent of real illnesses rather than to catalogue the many aches and pains which are present in the majority of individuals, it is felt that the main object has been attained, and that the Winchester Survey gives a representative picture of the extent of real illnesses, as well as some indication of the extent of minor ailments.

During the year preceding the survey, 3152 individuals were reported as sick. This comprised 32.4 per cent of the surveyed population of Winchester. About one-sixth of those sick had more than one illness during the year, as 2581 reported one illness, 465 reported two illnesses, 87 reported three illnesses, and 4 reported five illnesses.

The nomenclature of diseases is that which was furnished the investigators by the householder. No attempt was made by the surveyors to make these causes conform with those of the International Classification of Causes of Death. The morbidity nomenclature tells what the people, themselves, complained of as sickness. Of striking interest is the fact that only one-half of the mothers who bore children during the year considered normal childbirth an illness. Upon questioning, mothers would repeatedly say that childbirth was a normal function and that they were not sick. In the Italian district this was particularly marked, as only one-seventh of the childbirths were reported to the surveyors.

During the period covered by the survey, 149 residents of Win-

** In the subsequent tables, morbidity is represented by data from the survey alone.

chester died. These cases represented morbidity during the year but were not included in the tabulation of the survey. In order to obtain the correct morbidity rate, the mortality rates have been added to the morbidity rates obtained from the survey in Tables II and III.**

The incidence of most of the diseases is too small to make adjusted rates for age and sex. The same applies to nativity adjustments. In Table III an attempt has been made to give some idea of the age and nativity distribution in all types of illness. This table shows that the Irish and the Italians have lower rates than the native born and the Canadians. While these differences for "total all ages" are statistically significant, it is believed that other errors than mere chance enter in, as we find that the total time lost from sickness for these respective groups is larger among the nativity groups that give the lower incidence. The error, doubtless, is due to the probability that the Irish and the Italians reported only the more severe illnesses, although it is admitted that there may be real differences.

Total "	407	303	297	418	335			407	

* No rates computed where the population of the age groups is very small.

In all the age groups the females have higher morbidity rates than the males. The ratios of the rates vary from 1.07 in the 16-25 year group, to 1.44 in the 56-65 year group, with the ratio for all ages of 1.24. A second ratio for all ages was computed, omitting childbirth and diseases of the female genitals. This ratio (1.20) shows that sickness is more common among women even under these conditions. This phenomenon is not confined to Winchester alone. Sydenstricker¹ shows in his morbidity study of Hagerstown that the ratio of sick females to males was 1.28; and omitting childbirth and diseases of the

female genitals the ratio was 1.16. The ratio of the death rates among females to that among males in Winchester for the past 23 years is 0.94. Females apparently have more sicknesses than males, but the death rate is less. The relation between sickness and time lost is shown in Table IV.

The total number of days lost from illness in Winchester was 12,904. Accidents accounted for 2898 days, respiratory diseases 2570 days, intestinal diseases 1244 days, stomach complaints 965 days, heart affections 923 days, and the remainder were distributed among various other conditions.

The types of illnesses were studied in relation to the economic status of the individuals. When all diseases are considered collectively, there are significant differences between the rates for the various economic groups, the poor having the lowest rate, and the comfortable and wealthy, the highest. Whether this depicts real differences or merely indicates that more minor complaints were reported by the well-to-do is difficult to ascertain. The only individual diseases where significant differences were found were in the respiratory group, accidents among males, and rheumatism and stomach complaints among females. In the respiratory group the reporting of colds for both sexes increased with better economic conditions. Accidents among males were more common in the moderate wage groups. This would be expected, as mechanics, electricians, and men exposed to hazardous occupations are largely in this group.

Stomach complaints and rheumatism are both significantly high in the comfortable and wealthy female groups, but this again may only indicate differences in reporting. The rates for the diseases with significant differences are given in Table V.

There are slightly significant differences in the per cent of cases that employed physicians in the different groups (Table VI).

There is no significant difference between the percentage of sick males and females who consulted physicians; the respective rates being 78.8 for the males and 77.8 for the females.

Of the total cases of sickness 78.4 per cent employed a physician. There are no significant differences between the various nativity groups in regard to the employment of physicians, but the Italians and Canadians show lower rates than the other groups. There is a possibility that if the native born children of these various nativity groups were included with their parents, these differences might be significant. The percentage of physicians employed varied considerably with the different complaints. Table VII shows this for the more common diseases.

				21.0

Six physicians reported attending 235 cases during the week of June 1 to 7, 1927. If the physicians who did not report their cases had seen a similar number of cases to those who furnished reports, there would have been 548 cases attended by physicians during that week. If this represents 78.4 per cent of all the cases, there would have been 699 people ill in Winchester at that time. Our surveyors found

705 illnesses at the time the call was made. This gives added weight to the conclusion that the data collected is fairly representative of the true conditions in the town.

An attempt was made to determine the hospital and nursing facilities in Winchester by studying the records of the Visiting Nurse Association, by ascertaining the number of admissions to the Winchester Hospital, and by questioning a sample group of the surveyed population. The results indicate that Winchester is meeting the present demand for hospital and nursing care.

In the last fiscal year, the Winchester Hospital admitted 365 patients who were residents of the town, comprising about 3 per cent of the population. The proximity of Boston leads to the belief that many other patients went to other hospitals. Of these admissions, 87, or 23.8 per cent of the total Winchester admissions, were for childbirths, comprising 44.3 per cent of the births in Winchester. An additional 19.1 per cent of the births were hospitalized in out-of-town hospitals, making 63.4 per cent of the births in Winchester hospital cases. The per cent hospitalized by nativity is shown in Table VIII.

TABLE VIII
HOSPITALIZATION FOR CHILDBIRTH: BY NATIVITY OF MOTHER
(Rate per 100)

United States	Ireland	Italy	Canada	Other	Total
78.7	75	14.9	88.8	71.4	63.4

Since the numbers are so small, the maternal death rate by nativity is not included, as unwarranted inference for or against the quality of hospital service might be drawn.

Twenty-seven cases of respiratory diseases were hospitalized in the Winchester Hospital. This represents 1.5 per cent of the number obtained in the survey, and 7.4 per cent of the total admissions of Winchester patients to the hospital. The average length of stay for patients who were discharged alive from the hospital was 7.9 days, for those who died 3.4 days. The average length of stay for respiratory cases was 10.7 days, and for confinement cases 14.0 days. A large number of tonsil and adenoid cases made the average length of stay short.

About 10 per cent of the families in Winchester employed visiting nurses. These nurses cared for 1 patient in 193 homes, 2 patients in 69 homes, 3 patients in 3 homes, and 4 patients in 1 home. In the sample group interviewed by the surveyors, it was found that district nurses, practical nurses, and private nurses were employed about equally. As the surveyors queried only 63 families who had employed nurses, it is impossible to state whether the population at large would have shown a like distribution.

The private duty nurse received a salary ranging from \$42 to \$49 a week, being employed from a few hours in some instances to 83 days, the median time being 2 weeks. The practical nurse received from \$15 to \$35 per week, being employed from 4 days to 3 years, the median being 5 weeks. Nurses were employed for a great variety of causes, the chief one being childbirth. Two nurses were hired merely to help with the housework. As a general rule, the nurses employed were satisfactory, and there was no complaint of difficulty in securing their services.

CONCLUSIONS

1. The population of Winchester is not exactly representative of Massachusetts as a whole, as Winchester has an older population, an excess of females and fewer foreign born.

2. The findings of the survey are felt to be fairly accurate for the more serious illnesses, and considerably less accurate for such minor ailments as a headache, slight cold, etc.

3. Thirty-two per cent of the group surveyed reported being ill during the year preceding, an average of 1.2 times.

4. The crude morbidity rate for all reported illnesses was 409 per 1,000, the largest single group being colds and grippe with a rate of 152.

5. The Italians do not consider childbirth an illness, and most of the confinements occur at their homes.

6. Females have a higher morbidity rate than males, but a lower mortality rate.

7. The average time lost by wage earners for illness was 5.1 days. The average time lost by males was two and one-half times that lost by females.

8. There are apparent differences among the different nativity groups but these may be due to unknown errors. The Italians and Irish have low morbidity rates but have greater average time lost than the other nationalities. The Italians and Canadians employ doctors to a less extent than the other groups, but the small numbers make this finding insignificant statistically.

9. The number of illnesses reported increased with the economic status of the individual for all diseases as a whole, as well as for respiratory diseases, for rheumatism, and for stomach trouble among the females. Accidents were greater among males in the moderate economic group.

10. The percentage of physicians employed increased with the economic status.

11. Nursing and hospital facilities are apparently adequate to the present demand in Winchester.

12. The findings of this study emphasize the advisability of conducting similar surveys in connection with larger populations in order to eliminate the errors of chance fluctuation.

NOTE: Acknowledgment is made of the valuable aid given by the surveyors: Anna Crivello, Mary Cronin, Mrs. Filip Forsbeck, and Dr. Florence Hopkins. Without their indefatigable and intelligent services, together with their enthusiastic coöperation, this survey would not have been possible. Recognition is made of the assistance rendered by Estella L. Power in the compilation of the various tables, and by Dr. Carl R. Doering in their analysis.

Problems in the Prevention and Relief of Heart Disease*

WILLIAM C. MUNLY, M. D.

New York, N. Y.

THERE is definite information concerning certain phases of heart disease; but there is much evidence which is controversial; and, of more importance, there are many phases of heart disease about which little or nothing is known. Many of the problems concerned in the prevention and relief of heart disease fall into this third category. The problem of what causes heart disease may be taken as an example. It is obvious that heart disease cannot be prevented unless the etiology of heart disease is known. Yet if one glances through a textbook of medicine it will be found that heart disorder is mentioned as a complication of many diseases, particularly the infectious diseases, listed therein. While this is true, it is true also that in many diseases, cardiac complications are extremely rare. Certainly the majority of the cases of heart disease do not have a varied etiology.

It is fairly well established that there are three common types of heart disease: rheumatic, syphilitic, and arteriosclerotic. We know definitely the cause of syphilitic heart disease; we are approaching a knowledge of the cause of rheumatic heart disease; but we know nothing of the cause or causes of that form of heart disease which is conveniently described as arteriosclerotic heart disease.

Curves of mortality statistics show that there is a continuous increase in the number of deaths due to heart disease. To approach the problem of prevention in an intelligent manner it is necessary to have, first, a comprehensive knowledge of the incidence of heart disease, that is, an understanding of the size of the problem; second, a knowledge of the causes, more particularly the common causes, if any; and third, a knowledge of the natural history of the different types of heart disease.

Some progress has already been made with regard to our knowledge of the incidence of heart disease. Drolet¹ tells us that heart disease in New York City is now responsible for more than one-fifth of all the annual deaths. He states that in 1925 deaths from all causes in New

* Read before clinic and dispensary workers, arranged by the Joint Program Committee of the Associated Out-Patients Clinics of the New York Tuberculosis and Health Association and The North Atlantic District of American Association of Hospital Social Workers, New York, N. Y., February 10, 1927.

York City totalled 71,864, of which 15,651 were due to heart disease, or a rate of 266 per 100,000 population. The mortality rate for pneumonia followed at 143 per 100,000, cancer at 115 for 100,000 and tuberculosis at 93 per 100,000 population. Yet in 1910, the total deaths from cardiac conditions numbered 8,350, or only one-half of what they are now, the death rate being 175 per 100,000 population, or 34 per cent lower.

These figures show that heart disease is the leading cause of death in New York City now and that it has increased rapidly in recent years. On a basis of similar reports it is estimated that almost 2,000,000 people in the United States suffer from heart disease.

Further data on the incidence of heart disease are given in the result of a study, made by the Heart Committee of the New York Tuberculosis and Health Association in coöperation with the Board of Education, on 1078 newsboys in New York City. These boys ranged in age from 10 to 17. It was found that 16, or 1.5 per cent, had organic heart disease. Among these, more than one-half presented a history of rheumatic infection, especially rheumatic fever; one-third had a history of tonsillitis and no other rheumatic infection and one-third gave no history at all of rheumatic infections.

Similarly I have examined recently, 1000 recruits for the United States Army, drawn from the New York area and ranging in age from 18 to 35. The incidence of heart disease in this group was 15, or 1.5 per cent. These cases all presented the lesions typical of rheumatic heart disease.

These studies, however, do not indicate the entire problem. The figures cited, for example, simply indicate that heart disease as a whole is the greatest single cause of death and that its incidence is rapidly increasing. We desire to know the types of heart disease which make up this total, and their rate of increase or decrease. In this total are there certain forms of heart disease which we can reasonably hope to prevent? and if so, what are they? and are they on the increase at the present time?

Moreover these samples are not sufficient for an accurate knowledge of the incidence of heart disease as it occurs in this country. Studies of samples from various parts of the United States might throw light on the regional distribution of the different types of heart disease, and answer the question as to whether or not a particular climate is conducive to the development of a particular form of heart disease. Furthermore, those studies would emphasize to the public the great economic loss to the country as a result of heart disease.

Strange as it may seem, for centuries heart disease was considered

almost entirely from the viewpoint of structural changes in the heart, that is to say, from the pathological standpoint. The pathologist learned to recognize structural lesions of the heart and the clinician spoke of "myocarditis," "mitral stenosis," and "aneurysm." Such diagnoses were considered sufficiently descriptive of individual cases. Later the interpretation of heart disease from the functional standpoint was conceived; that is, disordered function of the heart, and we began to hear of such functional diagnosis as "cardiac failure," "auricular fibrillation," and "hypertension." Thus we learned to consider heart disease from its pathological or structural standpoint and from its functional aspects.

Within recent years, due in most part to the rapid increase in the incidence of heart disease, the etiology or cause of heart disease has been and is being more carefully studied. So that now heart disease is being considered also from its etiological aspects.

One of the earliest studies on the causes of heart disease, as they are now classified, was made by Cabot² in 1914. His sample for study consisted of 600 hospital cases in which a failing heart was the most notable feature. Briefly, he found that rheumatic heart disease made up approximately 45 per cent of the total; arteriosclerotic and hypertensive heart disease about 34 per cent; syphilitic heart disease 12 per cent; thyroid heart disease 1 per cent; and heart disease of unknown origin 5 per cent.

More recently Wyckoff and Lingg,³ made a study of 1001 cases of heart disease, of which 85.4 per cent were among cardiac clinic patients and 14.6 per cent among private cases. They found that about 25 per cent of the cases presented rheumatic heart disease; about 40 per cent arteriosclerotic heart disease; about 10 per cent syphilitic heart disease; and about 10 per cent heart disease of unknown cause.

Similarly,⁴ I have recently analyzed 1300 cases of heart disease, using for study a mixed group of adults comprising ambulatory cardiac patients attending a cardiac clinic, and hospital bed patients. In this sample, the rheumatic type comprised about 35 per cent of the total; the arteriosclerotic type 33 per cent; syphilitic type 8.5 per cent; and unknown heart disease 20 per cent. All other causes comprised less than 4 per cent of the total.

While the incidence of the different types of heart disease in the studies described differs to some extent with different observers, it is striking to note that over 75 per cent of the cases in these series can be classified under three types: rheumatic; arteriosclerotic and syphilitic. In each study there have been a number of patients with heart disease of unknown cause. In two of the series it is believed that the unknown

group is made up for the most part of patients having rheumatic heart disease in which that disease was the only manifestation of the rheumatic infection.

These figures are significant but similar studies are needed of samples taken from different parts of the country before a comprehensive knowledge of the causes of heart disease is obtained.

It appears that the infectious types of heart disease, which are the rheumatic and the syphilitic, make up from 35 to 45 per cent of all types of heart disease and that the so-called senescent or degenerative form, such as the arteriosclerotic type makes up a like percentage.

ARTERIOSCLEROTIC HEART DISEASE

Considering first, the so-called degenerative types of heart disease—those types associated with arteriosclerosis, arterial hypertension, Bright's disease and those alterations in the heart which occur in old age—have we or can we in the near future, hope for any method for their prevention? Probably not. We have no established facts concerning the prevention of the degenerative types of heart disease. It is true that much has been written of the physical stress and nervous strain of the present-day mode of living as a factor in the production of high blood pressure and hardening of the arteries. Also emphasis has been placed on the rôle of improper diet, obesity, general toxic conditions, overwork, unsanitary conditions, excesses, and focal and general infections as causes of this form of heart disease. While no preventive methods are at present known for this type of heart disease, people can be taught the right way to live. Though we cannot cure this disease, we can hope to relieve some of the suffering produced by it and thus hope to prolong life.

It has been suggested that when the statistics are analyzed further it may be discovered that the increasing rate of deaths actually takes place in this group and not in the infectious group in which the possibility of prevention and cure remains open. That is, if the increase in death rate from heart disease is due to an increase in the degenerative or old age form of the disease, then it might indicate that fewer patients are now dying from preventable disease in youth and middle life. Curves of mortality rates for infectious diseases and for heart disease which Cohn⁵ has had prepared actually suggest this. Practically parallel with a decrease in deaths from the preventable infectious diseases there has been a corresponding rise in the mortality curve of heart disease. This may temper our excitement concerning the increasingly high mortality from heart disease.

SYPHILITIC HEART DISEASE

In the studies cited 8 to 10 per cent of the total number of cases of heart disease observed had their origin in a syphilitic infection—yet syphilis is preventable.

It is known that there is usually a latent period of from 15 to 20 years from the date of the original syphilitic infection to the onset of symptoms of heart disease. No doubt the syphilitic infection has attacked the blood vessels and heart during this period, but the disease is usually not recognized until the onset of the heart symptoms causes the patient to seek relief. Thus there is a period of many years during which adequate treatment might arrest and even cure the disease.

Periodic health examinations, by disclosing the lesions of syphilitic heart disease in its early stages, and systematic treatment would probably prevent serious damage to the heart. Thus if a proportion of this rapid increase in heart disease is found to be due to the syphilitic type, there are known preventive measures and a recognized treatment.

Syphilitic heart disease constitutes a serious problem, for its symptoms make their appearance during the most productive periods in a man's life, that is, between the fortieth and sixtieth years.

Further information is needed concerning the progress of syphilitic heart disease during the latent period.

RHEUMATIC HEART DISEASE

In the studies mentioned, rheumatic heart disease constituted from 25 to 35 per cent of the total. Moreover, it is probably no exaggeration to state that from 1.5 to 2 per cent of the children and young adults in New York City have rheumatic heart disease. Since it is principally an affection of children and young adults, which seriously cripples many of them, our interest is directed particularly to it.

What is the nature of this disease? Until recently, rheumatic fever was regarded generally as having arthritis or inflammation of the joints as its principal manifestation. When heart disease occurred it was considered a complication of the joint inflammation. However, rheumatic fever is now commonly regarded as a general infection, which when it invades the joints causes polyarthritis or "inflammatory rheumatism"; when it lodges in the brain it causes chorea or St. Vitus' dance; and when it involves the heart, it causes rheumatic heart disease. Other evidences of this rheumatic infection may be tonsillitis, muscle, joint or "growing" pains, torticollis, or wry neck, and certain skin conditions known as rheumatic nodules, purpura, and various erythematata.

Rheumatic heart disease is primarily a disease of children and young adults. It is rare after 50 years of age, and the majority of

cases occur before the age of 30. Rheumatic fever usually shows itself in youth as pains in joint or muscle, St. Vitus' dance or inflammatory rheumatism. The heart is often affected simultaneously or just following these ailments. More important still the heart may be the first and apparently the only structure involved, so that there may be present rheumatic heart disease without any other evidence of rheumatic fever.

This is a chronic disease with no definite course, but rather an extremely variable one. Some cases are immediately fatal; some are characterized by more or less continuous active heart infection from first infection to death; some have alternate periods of activity and latency; and some have an initial active period of heart infection and then becomes apparently inactive for a long period of time.

It is thought that rheumatic fever and its various manifestations are caused by a germ, although the exact organism is not known or proved at present. Furthermore, since many attacks of rheumatism are preceded by attacks of tonsillitis, it is believed that the germ causing rheumatism may enter the body through diseased tonsils. Other portals of entry may be decayed teeth or diseased gums, although this is not proved. It seems logical, therefore, that every possible means should be employed to keep tonsils and teeth healthy. If they become infected they should receive appropriate treatment so that germs from these sources may not enter the body.

It is well known that patients with rheumatic heart disease are susceptible to infections of all kinds. Mild infections such as bronchitis, sore throat or "cold," have a bad influence on this type as well as on all other forms of heart disease. Therefore, patients suffering from heart disease should be advised of the value of oral hygiene and the danger of colds, sore throat, and infections.

There are many other factors which demand attention, such as the seasonal variation and family incidence of rheumatic heart disease. One is often impressed with the occurrence of rheumatic heart disease in more than one member of the same family. Many observers have called attention to this. Is there a direct infection from one member of the family to another? If so, measures of isolation such as those employed in the contagious disease should be instituted.

Again it is important to know the incidence of rheumatic fever in our communities and the frequency with which the heart is affected in these cases. Should rheumatic fever be made a reportable disease?

RELIEF OF HEART DISEASE

Considerable knowledge is available at the present time concerning the immediate relief of the symptoms produced by heart disease. This

is demonstrated daily in clinics and practice and it is not my purpose to discuss the treatment of heart disease. But what is known of the end results of treatment, of cardiac vocational guidance and careful social service follow-up? Certainly much is yet to be learned. Furthermore, much more information is needed as to the natural or life history of the different types of heart disease, their respective durations and the effect of remedial measures on their course.

Further study is necessary covering the numerical distribution of heart disease in different parts of the country and the proportion of the various types of heart disease. How many cases are due to infection and how many belong in the degenerative or old age group? What is the effect of treatment on their duration? Is the duration modified by differences in social and economic environment? by convalescent care? and by vocational guidance? Have diseases of the tonsils and teeth a bearing on the incidence of rheumatic infection? What is the direct cause of rheumatic fever?

There is need for carefully collected data dealing with the convalescent care of cardiacs in order to evaluate properly its importance. There is a need for information showing how much and what types of work children with heart disease can do.

The value of careful social service work among cardiac patients is fully recognized, but further study and the collection and critical analysis of more data are necessary before its importance can be fully evaluated.

It is appreciated that the collecting of data is a laborious task, and that the tabulation of those data is still more laborious; but we should appreciate that it is a means at the disposal of all clinic workers, social workers, nurses and physicians of increasing our knowledge of the problem of the prevention and relief of heart disease.

The Preparation of Acidophilus Milk

FRANK E. RICE

*Professor of Biological and Agricultural Chemistry, North Carolina State College,
Raleigh, N. C.*

INTESTINAL toxemia and sour milk therapy are subjects that are far from being on a scientific basis. But it has been demonstrated, at any rate, that milk containing lactic acid is more readily digested than "sweet" milk, whether the acid is a result of bacterial activity or a result of the addition of U. S. P. lactic acid, as is the custom in preparing infant feeding formulas. Furthermore, it has been demonstrated that it is possible under certain conditions to implant the acidophilus type of bacillus in the lower intestinal tract of both man and animal to such an extent that it predominates over all other types. No doubt, too much has been claimed for sour milk therapy; yet there is a preponderance of evidence to support the view that the *B. acidophilus* culture may be employed in such a way as to have therapeutic value.¹

In order to have therapeutic value, the culture must contain enormous numbers of bacteria. James² has shown how the average commercial culture falls down in this respect. A large amount of the culture should be taken daily; and lactose or dextrin or some other carbohydrate that is rather slowly absorbed should be fed at the same time.

The kind of culture most satisfactory for supplying the acidophilus organisms in large numbers is a freshly prepared milk culture. Tablets, candies and emulsions have not received the unqualified approval of the Council on Pharmacy and Chemistry,³ and any broth culture which has been kept at a refrigerator temperature cannot contain many virulent organisms on account of the fact that they die out rapidly at low temperatures. In a few cities acidophilus milk may be purchased for from \$.50 to \$1.00 a quart, but it is generally not available at all even at such a price. However, by observing a little care it may be prepared in the home at a very low cost.

The Milk Supply—To start with, the milk must be free from those bacteria which naturally occur in fresh milk. This can be attained by boiling ordinary market milk for a long time, but it has been found that unsweetened evaporated milk is particularly suitable for this purpose. It can be obtained from the grocer at a fair price, can be kept on hand

always ready for use, and it is certainly sterile. Evaporated milk has been sterilized under rather high steam pressure (about 11 pounds); this is sufficient just to begin to caramelize the milk. Kopeloff¹ has shown that when milk is autoclaved to a "light caramel color" the acidophilus organism grows more rapidly in it than in milk heated to a lesser degree.

The Starter Culture—It is now possible to obtain a pure broth culture of *B. acidophilus* at, or through, all drug stores. The product of a reliable manufacturer should be specified. One culture which we obtained proved to be *B. bulgaricus* though it was labeled "*B. acidophilus*."

The Control of Temperature—The acidophilus organism grows best at 90° to 105° F. It exhibits less growth at lower temperatures, though it has been found that the organism produces acid at a considerable rate even at room temperature. (Four observations showed an average increase of 0.65 per cent lactic acid in 24 hours at 68° F.)

Milk that has been inoculated can be warmed to 100° to 105° F. and transferred to a thermos bottle where it will maintain a temperature high enough to permit very satisfactory growth in 15 to 24 hours. The rate at which the temperature falls off depends upon the quality of the bottle and also, of course, on the temperature of the surrounding air. But it has been found that beginning with a temperature of 100° F., a quart thermos bottle of average quality will permit the temperature to drop no more than 10° to 15° in 24 hours. Such temperatures are found quite satisfactory for the rapid production of acidophilus milk.

The Procedure—Carefully clean a quart thermos bottle by allowing it to stand over night full of water containing some washing powder or a little household ammonia; then scald it. Place the cork, a can opener and thermometer in a pan and pour boiling water over them. Wipe the top of a one-pound can of evaporated milk free from dust and pour boiling water over it. Open the can and pour contents into the pan that has been scalded. Fill the can with boiling water and pour into the evaporated milk. Immerse the pan in cool water and stir the mixture with the thermometer until the temperature comes down to about 105° F. Add 2 or 3 ounces of commercial *B. acidophilus* culture, mix, and transfer to the thermos bottle. (The temperature should now be between 100° and 102° F.) Cork and let stand for 24 hours, or until the milk has acquired a pleasantly sour taste. When this is attained, transfer to a clean milk bottle and place in the refrigerator.

Succeeding cultures of acidophilus are prepared by using about a teacupful (6 ounces) of milk culture previous made to inoculate the

diluted evaporated milk for the next run. Proceeding in such a manner, it will be found that acid is produced at a more rapid rate than when the first quart was prepared using the commercial broth culture as a starter. Thirteen to 17 hours is now quite sufficient. If fermentation is allowed to proceed for a longer time so much acid is developed that the taste becomes unpleasantly sour.

After a little experience one may stop the action of the bacteria at any desired degree of sourness. This is effected by merely transferring the milk to a clean glass bottle and placing in the refrigerator. It is perfectly safe to keep the culture at room temperature, but, as has already been mentioned, a considerable increase in acidity may be expected. This is of little consequence, however, if the product is consumed within 24 hours. On the other hand, if the milk is kept in a refrigerator it should be consumed within 48 hours for the reason that the organisms rapidly die out at such low temperatures.

One or two tablespoonfuls of lactose or dextrin may be added to each glass of milk consumed, though the pleasant tart taste of the sour milk is to some extent injured by this addition. Most people prefer to take the carbohydrate separately.

Typical acidophilus milk has a fine grained curd. It is rather viscous, especially at low temperatures, but not "stringy." It does not develop so high an acidity as is produced by the *B. bulgaricus*. When a culture becomes rapidly very sour or bitter and is extremely viscous so that when poured from a bottle it runs out in strings, it is an indication that the culture used was *B. bulgaricus*. This should be discarded and a new commercial culture obtained from a different source. At any time when souring does not seem to be taking place normally a new start should be made.

The nutritive value of this product is exactly the same as that of ordinary cow's milk. Evaporated milk is whole cow's milk evaporated down to one-half its bulk. Therefore, by diluting a can of it with an equal amount of water the composition will be the same as that of normal cow's milk. The evaporated milk flavor, which is objectionable to some people, is scarcely noticeable in acidophilus milk prepared from that product.

Some Experimental Results—A large number of milk cultures have been prepared in thermos bottles on which observations have been made of the influence of (1) the amount of old culture used for inoculation, (2) temperature at beginning of fermentation, and (3) length of time during which fermentation is allowed to proceed. Table I shows the influence of these variables upon the rate of acid development, which is to some extent a measure of the viability of the culture.

TABLE I

INFLUENCE OF AMOUNT OF INOCULATION, TEMPERATURE OF STARTING, AND TIME, ON THE AMOUNT OF ACID PRODUCED BY *B. acidophilus*

Amount of Culture	Temperature	Time in Hours	Per cent Lactic Acid Produced
1 oz (1 cup)	102°	17	0.77
6 oz (1 cup)	102°	17	0.92
9 oz (1½ cup)	102°	17	1.01
6 oz	90°	17	0.88
6 oz	102°	17	0.92
6 oz	105°	17	1.07
6 oz	102°	0	0.68
6 oz	102°	13	0.85
6 oz.	102°	17	0.92

It has been found that acidophilus milk has its best flavor at 0.8 to 1.0 per cent lactic acid. The result of these observations led to the conclusion that the best results are obtained by the use of about one teacupful of old culture to inoculate one quart of diluted evaporated milk, starting the fermentation in a thermos bottle at 100° to 102° F. and allowing the fermentation to proceed for 13 to 17 hours. For the first inoculation, however, where the commercial broth culture is used, fermentation should be allowed to proceed for 24 to 27 hours.

The fact that the commercial culture is much less active than the prepared milk culture when used for inoculation shows how much greater must be the therapeutic value of the latter.

Salem Sewage Plant

SALEM proposes the second activated sludge plant to be built in Ohio, following closely on the Elyria installation. Plans for the Salem plant were approved in June. The plant is a typical one, comprising presedimentation; aeration by air diffusion with horizontal spiral flow; and separate sludge digestion of mixed fresh and excess activated sludge. F. S. Barckhoff, city engineer, designed the plant, with the assistance of C. C. Hommon, biologist and chemist.

Making Cities Livable

BLEEKER MARQUETTE, FELLOW A. P. H. A.

Executive Secretary, Public Health Federation, Cincinnati, O.

DURING the country's entire history American cities have grown in haphazard fashion, mixing varnish factories, paint shops, slaughter houses indiscriminately with residence neighborhoods, allowing the development of congestion and potential slum areas to go on with little check. Now, within the short span of 10 years, more than 550 communities have adopted zoning to protect themselves against these developing evils. No doubt because of the very acuteness of its problems, New York, in which zoning was a more complicated and difficult matter than in probably any other city in the country, was the first to undertake zoning.

Although a pioneer in this movement, New York's zone plan has served as a valuable example to the rest of the country. Too much praise cannot be given to the intelligence and wisdom of the group of men who were responsible for the formulation and the enactment of the New York Zoning Law. To take a city the size of New York and divide up its enormous areas into business, residence and industrial zones, and to determine height limitations and open space requirements for these zones was a great task. To have done this in a way that was accepted as sound by building and real estate interests and that has proved, by experience, to be in error in a comparatively small number of cases, was a monumental achievement.

One of the most remarkable things about it has been the fact that not a single case affecting the constitutionality of the New York law has reached the courts. This has been due in no small measure to the wisdom of the promoters of the law in creating a board of appeals with power to vary the strict letter of the law where necessary to prevent unnecessary hardship. Naturally in a city where the land values are among the highest in the world, many compromises had to be made with economic necessity. The standards set are not high enough to protect the outlying districts adequately and they fall far short of being safe for other communities to follow, but nevertheless to New York go the laurels for having established the principle that a city can regulate its building development for the welfare of its citizens.

What it is going to mean to America 50 or 100 years from now to have our cities developing in orderly fashion, with ample space for sun-

light and air in the buildings in which we live and work, and play space for children, should appeal to the imagination of the health worker. The men who have fought the intelligent, persistent battle which has convinced community after community of the need of zoning and who have helped to gain the support of the courts have made a great contribution to the health, comfort and general welfare of our city populations of the next generation. Belief in the importance of zoning to health has been one of the most influential factors in the rapid advance of zoning, and yet it has been a difficult factor to establish because of the lack of conclusive scientific evidence.

The social factors bearing on health are so many and so interrelated that it has not yet been found possible to separate completely the effect of physical environment from such influence as income, race, education and medical service. Nevertheless, fortunately, all the evidence we have from experience and observation makes a case strong enough to have convinced legislators and courts. The city which provides adequate open spaces for all buildings in which people live and work, checks excessive congestion, and keeps objectionable industries out of residential neighborhoods, should certainly be more healthful than one with the haphazard building development that has characterized the typical modern city.

There is little doubt that the time will come before many years when we shall have scientific data to prove our case conclusively. Meanwhile practical considerations indicated that, rather than go on piling up trouble for ourselves in the future, the sensible thing to do was to act upon the evidence provided by our experience and by the testimony of competent people, and proceed to attack the problem without waiting for more scientific data.

Certainly there can be no question that when we build hospitals and sanatoria for the sick we build them with ample open spaces to insure an abundance of sunlight and fresh air. No one would advocate that, pending the producing of conclusive evidence to the contrary, we should put these institutions in congested areas with no thought of sunlight and air. If these considerations are important in nursing the sick back to health they are no less important in maintaining the health of all.

Nothing in the modern progress of medical science has been more important than the proof of the value of sunshine. If sunshine will both cure and prevent rickets, if it is a great aid in the treatment of tuberculosis of the bones and joints, if it is helpful in building up vitality and resistance to disease in children and in adults, then we have a strong argument for controlling city development in such a way as to

prevent congestion and guarantee open spaces sufficient to permit some sunshine to enter. So strong is the case for the value of the sun's rays that the day is probably not far distant when we shall require all residences to be so oriented as to provide the maximum of sunshine in living rooms and when we shall require in new buildings window glass that will not screen out the ultra-violet rays.

More is known about ventilation than ever before. The fundamental requisites are motion, temperature and the proper amount of humidity. For schoolrooms modified window ventilation has proved to be the most desirable of all known methods. The adequacy of open spaces surrounding structures will certainly play an important rôle in determining whether these air conditions can be provided. Obviously, the room facing on a narrow court will have little air motion and in summer will have an excessive temperature.

The fact that those sections of a community in which the infant mortality and the death rates from tuberculosis are highest are usually those in which the congestion is greatest and the open spaces least, furnishes strong evidence that these conditions are factors perhaps of equal importance with low income, race and education. A recent study of infant mortality in Cincinnati has shown among other things that in the wards having the highest density of population the death rate among children under 1 year of age is appreciably higher than in the others. Drolet in his study of tuberculosis among the Jews of New York City produced facts indicating that while there is a distinctly favorable racial resistance to this disease, it is significantly more deadly in the congested tenement areas even though the economic status is not greatly different.

Where any factor so consistently accompanies high death rates from this disease, the presumption is strong that it cannot be eliminated as a cause. There has been a strong tendency to discount the influence of physical environment because of the fact that, without any great change in environment, it is possible to reduce mortality by means of improved medical and nursing care, education, better nutrition and other methods used in the modern health movement. This view, however, overlooks the fact that this improvement is made in spite of the environmental handicap and with no knowledge of the extent to which bad environmental conditions definitely limit the extent of our progress in the poorer city districts, or how much greater the results might be if the physical surroundings could be transformed.

It is noteworthy that Seattle, Wash., which stands among the highest of all cities in its percentage of home ownership, is among the lowest in infant mortality rates. Dr. Leonard Hill, the noted English

authority in his book *Health and Environment*, points out that in England "rural districts still maintain the relative advantage over town districts which held in the olden days," despite the enormous amount of health work in cities.

The effect of permitting the intermingling of business and industry with residences is certainly not conducive to health promotion, though its ill effects do not lend themselves to ready measurement in terms of vital statistics. We must not lose sight of the fact that the goal of the public health movement is not alone the prevention of disease and premature death. Our objective is positive health building—achieving such robust health, mental and physical, as will make life enjoyable to its fullest extent. It would be an unusual person indeed who would argue that this objective is fostered by the congestion, noise, odors and smoke of the modern city. Smoke in particular is an evil which accompanies the business and industrial districts to an extent that is unnecessary in home neighborhoods. Smoke interferes with the sunlight, and deprives a community of a great deal of the beneficial sun's rays that it would otherwise have. Dr. Leonard Hill, in his book previously referred to, says:

The great medicinal value of sunlight in a cold climate is only very slowly being recognized. In some districts in England, owing to smoke, people in certain localities receive 50 per cent less actinic rays of sunlight than others only four miles distant from them.

The committee on Public Health of the New York Academy of Medicine in a statement published in the bulletin of the Department of Health of New York City on February 27, 1926, states, that it "viewed with great concern the health hazard which has been created of late by the continual, and to a large degree preventable, discharge of dense smoke into the air." The interference with the beneficent action of the actinic rays of the sun by the all-pervading smoke is detrimental to health, particularly of children. As time goes on we shall learn more and more in the way of definite facts regarding the detrimental effect of these things upon health, comfort and efficiency.

Keeping business and industry out of residential districts and increasing the size of open spaces greatly reduces the danger of fire and the resultant probability of injuries and deaths due thereto. The 1925 *Fire Prevention Year Book*, published by the Baltimore Underwriters, states that the fire hazard is almost seven times as great in buildings used entirely for business as in buildings used entirely for residences.

Leading psychiatrists and neurologists have testified that the protection afforded to residential districts by means of zoning is beneficial

to mental health. Horatio Pollock, statistician of New York State Hospital Commission, has shown that mental disease is much higher in urban than in rural districts of New York State. "The man of the rushing nerve-racking city is most likely to become insane," says Dr. Pollock, "while the woman of the more placid country district has the best chance of not suffering from mental disease."

Regardless of the dearth of incontrovertible scientific data on the relation of zoning and housing to health, few will challenge the conclusion that the city of the future which provides better housing, eliminates congestion, guarantees a reasonable amount of light and air for all buildings for human habitation, and keeps business and industry out of residential districts, is making for the day when people on the whole will enjoy more complete health. It is these considerations, along with evidence and testimony showing the relation to safety, to traffic congestion, to morals, to the cost of city utilities, and to convenience and economy in transportation, that have led the courts to declare zoning legal.

The past ten years have been crucial ones for the cause of zoning. At no time has there been any certainty that the courts would not yield to the cry of "taking property without due process of law," and deprive all cities of the benefits of zoning. Hundreds of cases have been heard, and step by step the case for zoning has been strengthened until now there is no longer any doubt of its validity. A reading of the many excellent opinions that have been handed down shows how strongly the health arguments have influenced the courts.

Edward M. Bassett of the Advisory Committee on City Planning and Zoning of the Department of Commerce, and one of the great leaders in the cause of zoning from the beginning, has prepared a statement recently published by the department entitled "Zoning Progress in the United States," in which he gives the present status of zoning from the legal point of view. Zoning was a wide deviation from anything that had been done in the past, affecting as it did every parcel of land existing in the community, setting a standard as to the use to which the land might be put, the height to which the buildings might be erected, and the open spaces required around them. It was a momentous thing for the judiciary to declare so radical a measure constitutional. The fact has been recognized, however, that the development of the large city has brought with it dangers that necessitate an entirely new type of regulation to prevent city conditions from becoming intolerable.

Zoning is done under the police power, which is that right of a community to enact necessary laws and regulations without having to

compensate the owner for any adverse effect he may believe such regulations may have upon his property values. Regulations adopted under the police power must be reasonable, must be applied equally, and must be based upon the health, safety, morals and general welfare of the community. Zoning has definite limits and Mr. Bassett points out that the community which attempts to zone without recognizing these limitations is very likely to find its zone plan invalid.

1. It is necessary that there be a state enabling act granting to communities specifically the power to regulate the height, bulk and use of buildings, the size of courts and the density of population.

2. There must be a careful scientific study of the needs of the community, public hearings and comprehensive and impartial application of the regulations.

3. There must be requirement of more than a majority vote of the council to effect changes after written protest of property owners.

4. There must be provision for a board of adjustment with power to vary the strict letter of the law and the maps, to avoid unnecessary hardships.

The constitutionality of zoning based on an enabling act and having due regard for these essentials has been upheld by the courts of every state where it has been tested except in New Jersey and Georgia. The most important decision ever rendered on the subject was that handed down in 1926 by the U. S. Supreme Court in the *Euclid Village* case. In that important opinion, almost every phase of modern zoning was referred to, and the court made it clear that intelligent, reasonable and systematic zoning is a proper exercise of the police power. With more than 30 million people, comprising over 55 per cent of the urban population, already protected by zoning, it certainly will not be long before every sizable municipality in the country will be included in the list. Few measures so drastically affecting property rights on the one hand and human welfare on the other have made such rapid progress.

Establish New Quarantine on Mussels

EXAMINATION of mussels, made recently by Dr. K. F. Meyer, director of the Hooper Foundation for Medical Research and consulting bacteriologist of the California Department of Public Health, has determined the presence of a toxic condition in these crustacea. A quarantine order was issued immediately upon the determination of these findings. The general public is warned to beware of eating mussels taken from the coast district specified in the quarantine order.

The Place of the Nursery School in a Public Health Program*

CHARLES A. WILSON, M. D.

Merrill-Palmer School, Detroit, Mich.

THE value of schools for young children has long been recognized in certain countries. In Belgium, as early as 1833, official recognition was given to such schools, and in 1905 there were 2,711 schools in that country for children from 3 to 5 years of age. These schools accommodated 258,149 children, a number probably representing half of all children of these ages in the country.

In France also the need for such schools has been admitted. The first school in France for children under 5 years of age was founded in 1771. In 1897, about 25 per cent of the children from 2 to 6 years of age in France were attending school. In 1904, there were 217 schools in Paris for children from 2 to 6 years of age. These institutions were educational, though probably not to the extent that we now expect them to be.

The first English nursery school was opened in London in 1900. Only a small number of nursery schools were established in England before the war, although the subject had received thorough and favorable consideration, as evidenced by the voluminous report published in 1908. In 1918, the Fisher Act provided for the establishment of nursery schools in England, in connection with the national education system. Their growth was somewhat retarded, however, by post-war conditions, and especially, economic conditions.

The educational advantages of the nursery schools have been widely discussed, and they are now well established, but the physical advantages, though even more evident, have not been discussed in the literature.

It is a well-known fact that most children reach the age of 5 or 6 years with physical defects which need correction. Many of the defects are so serious that the children are classified as abnormal. Yet medical literature gives abundant evidence that many of these defects are preventable. Therefore, medical practice with children has assumed, to no small extent, a preventive rôle.

The purpose of such preventive work is twofold—to develop proper

* Read before the Wayne County Medical Society, Detroit, Mich., March 27, 1928.

habits, and to give remedial attention at the proper time. Proper remedial care will prevent the development of more serious defects. It frequently consists of correcting improper habits. Proper food is a necessary corollary to the developing of proper habits. The early development of good food habits is generally admitted to be of great value; yet it is not uncommon to see clinic children whose families cannot afford to give them an adequate diet. Moreover, the indigent family and the family of moderate or good circumstances have given little real study to the preparation of the dietary and its presentation to the child. It is unusual, in fact, to find a family which has given thorough consideration to the proper methods of child care. Such a condition may be explained partly by failure to recognize the importance of early training; partly by ignorance, poverty, and lack of proper personality; and to a considerable extent by the conditions of city life, which necessitate living under conditions which make good child training impossible.

We believe the nursery school offers the best means of solving these problems, which are really public health problems.

Let us consider for a moment the objectives of the care and training of young children. They may be summed up as follows:

- To offer a proper environment for physical welfare, growth, and development.
- To offer opportunity for the best mental and social development.
- To offer opportunity to make as many judgments as possible.
- To offer as many educational opportunities as possible, that is, opportunities to learn how to do new things, things the child did not know how to do.

These objectives necessarily dovetail to some degree, since the final aim is an environment that gives opportunity for all-round development. If these objectives are approved, and it is admitted that the nursery school, combined with a program of parental education, may go far toward meeting them, we shall be asked for the group of children to which the nursery school will be advantageous.

It is too early in the history of the nursery school to say that it is the best place for all young children. However, it is safe to say that it would be advantageous to many children who do not now have its benefits, and that it would be of great value to practically all the children of the poorer classes and to many from the better classes of society. I believe that the nursery school is the best method yet proposed for caring for a large proportion of the children of large cities, and that the movement should be extended to accommodate such groups.

It is equally true, however, that the extension of this service must necessarily be slow. Nursery schools should not be established until properly qualified teachers and staffs are available. The need for such

restriction was recognized in the English report of 1908, which has the following statement:

The committee deprecate very strongly the idea which appears to be prevalent that any teacher is good enough for infants. They hold, on the contrary, that the care of these young children presents difficulties at least equal to those which arise in teaching the older ones, and the infant teachers should be selected with scrupulous care. . . . In the case of normal children more good can be done by education between the ages of 3 and 5 than at any subsequent period of 2 years; and experience shows that attendance at school before 5, even under the present conditions, undoubtedly helps in the great majority of cases the subsequent education.

Nursery schools should not, then, be organized more rapidly than proper personnel is available. The nursery school staff should have proper training and experience, favorable personalities, and should be free from any disease that would be a hindrance in the work.

The advantages of the nursery school are numerous, and though we are considering them chiefly from the point of view of physical welfare, it is true that the physical, mental, and social life and development of the young child are so interrelated that they cannot easily be thought of separately. The following are some of the advantages:

It provides an opportunity for parental education. Whether we are considering nursery schools, summer camps, clinics, or other health procedures for children, unless the parents are shown the value of the régime and coöperate with it, much of the effort is wasted. The American nursery schools have definitely included parental education as a part of their program.

The nursery school relieves the mother from the care of the child for a part of the time. This advantage is an important one from several points of view. That this very relief lessens parental responsibility and is therefore undesirable is a favorite point for critics of the nursery school to dwell upon. However, the nursery school does not take the child away from the mother for so long a time as some assert, and placing the child in the nursery school, when there is a program of parental education in connection with the school, actually increases the sense of parental responsibility. The objective of the nursery school is to supplement, guide, and indicate parental responsibility, not to replace it. It might easily be shown that the mother who has a few hours apart from the child each day for undivided attention to her other duties gives more and better planned time to the child after he returns from the nursery school. The busy child at home gets in the busy mother's way, and too many commands are necessary. The results are not the best for either the mother or the child.

In the home, the little child is not usually the most important consideration in making plans for the day, as he is in the nursery school.

In the nursery school, a teacher well trained in methods of dealing with young children is always present to give guidance when it is needed. She is better able to deal with the child's problems than is the mother, in most instances.

In the nursery school, the child is in an environment planned to meet his needs, with the proper equipment and materials available. Here he can make and carry out his plans, which is conceded to be an important part of the education of the young child, without undue interference. He has other children to play with and learn from. He learns how to live in the group and how to give and take. The equipment for both outdoor and indoor play is selected by competent people, to allow the best opportunity for the development of muscle and muscle coördination, and general body and mind control. It is, of course, more adequate than the equipment most homes can afford. The child in the home quickly outgrows toys and play equipment. The equipment in the nursery school is not outgrown, for the children there are always from 2 to 5 years of age.

It will be conceded that the child should have a maximum amount of free play in the open air. It will also be admitted that many city homes do not have facilities for outdoor play, and that, when they do, the mother is often called upon to follow or worry about every movement, with a result that could hardly be called either free play for the child or enjoyment for the mother. At the nursery school, plenty of space for outdoor play, as much time as weather conditions permit, play equipment, companions of the same age, and adequate supervision, are provided.

When lunch time comes at home, the mother is often busy, and sometimes has not planned the meal ahead; therefore, it is likely to be inadequate for the young child. In the nursery school, the meals are planned ahead, as the chief consideration is the welfare of the child, and the nursery school dietary furnishes those things most likely to be insufficiently represented in the home diet. Further, as it is generally considered best for the young child to have his main meal at noon, the nursery school provides this meal, carefully planned and selected, and the home coöperates by giving the child a breakfast and dinner complementary to this lunch. The nursery school teaches good food and health habits through example and practice, and the "social pressure" exerted by the other children makes the teaching of health habits easier than in the home.

In *The Normal Child—Its Care and Feeding*, Alan Brown makes the following statements:

The food suitable for the second year of life and the method of its preparation and administration are subjects upon which the masses are most profoundly ignorant. A few children at this period of life are underfed, but the great majority are overfed; they are carelessly given, at improper intervals, unsuitable food, wretchedly cooked. . . .

With many children this expansion of the diet list is attended with considerable difficulty. They are thoroughly satisfied with the milk and refuse all other forms of nourishment. In such cases time and patience are necessary at feeding time. . . .

A child should never dine with adults until he can have an adult diet, if circumstances of the family will permit him to dine alone or with other children. It is a species of cruelty to expect a hungry child of tender age to sit at the table, see and smell fragrant dishes, and be forced to content himself with his restricted fare without complaining. . . .

It may be safely said that a well, vigorous child is a hungry child; and nearly every child may be made thoroughly hungry three times a day by giving suitable foods at proper intervals. The children who come to a physician for poor appetite without evidence of disease to account for it are, almost without exception, improperly fed. They are often given unsuitable food at mealtime, when they are loaded down with sweets and pastries; but the chief error is eating between meals. This habit has ruined more appetites and has been the cause of more stomach disorders than any other one factor. . . .

Children who overexert themselves at school or at play, or who are easily excited and have plenty of opportunity for excitement, often suffer from loss of appetite. The management of these cases is to remove the source of the trouble, whatever it may be. An excellent means is an enforced rest for one and a half hours after the noonday meal.

Dr. Brown is quoted at length because the problems he discusses are so fitted for nursery school attention and because the nursery school has been so successful in dealing with them. Moreover, these problems are preventable if proper care is taken early. A properly ordered nursery school teaches habits that prevent these undesirable practices. If established, such habits yield better to the nursery school régime than to any other method of treatment.

Regular physical examinations and physical measurements, as well as measurements of mental and social progress, are a part of a properly conducted nursery school program. Such measurements need not be sufficiently elaborate for research purposes, but must be sufficiently thorough to show the course of development the child is taking.

The importance of the nursery school as a center for a public health program with young children is indicated by the fact that the English nursery schools were developed because of the health advantages to the children, as pointed out by Sir George Newman, Chief Medical Officer of Great Britain. The English nursery schools were established in an attempt to solve the problem presented year after year by the many children entering the elementary schools with defects of health apparently developed during the preschool years. During the 1926-27

school year, the Detroit Department of Health examined 26,878 first grade children.¹ Of these children, 64.6 per cent were found to have one or more physical defects. If one may assume, as seems reasonable, that this condition is representative of the country at large, the importance of attacking health problems during preschool life, in this country as in England, is evident.

In the United States, the primary purpose of the nursery school has been to develop an institution that helps parents in caring for and directing their children, as well as to supply an environment that offers the child the best possible opportunity for an all-round development, physical, mental, and social. Nursery school history in this country is of less than 7 years' duration. Its growth has been satisfactory. Close association with the universities of the country has kept the standards high and encouraged an attitude of investigation for the best methods of development. The leaders in the field believe that the increase in the number of nursery schools should be as rapid as trained personnel becomes available, but not more so.

From experience covering 6 years, the staff of the Merrill-Palmer School believes that the nursery school offers the best method of dealing with the greater proportion of children from 18 months to 5 years of age. They believe that it is the best place to develop proper habits and that it gives the best opportunity for physical and mental growth and development. Because of these advantages, the medical profession should be familiar with the opportunities the nursery school offers as a foundation for a public health program with young children and the parents of young children.

Tuberculosis Directory Published

HELPFUL to directors of local health departments and private health agencies is the Tuberculosis Sanatorium and Association Directories, recently published, which lists 1,454 organized state and local associations and 282 special committees which assist in the various phases of tuberculosis work. This directory is available from the National Tuberculosis Association, 370 7th Avenue, New York, N. Y.

Nutrition Experiments in the Schools of Winston-Salem, N. C.

ELEANOR WHITTINGHILL

Nutritionist, Department of Health, Winston-Salem, N. C.

THE aim of our nutrition program has been to prevent unnecessary illness and to increase the efficiency of the human body by teaching nutrition and its relation to health in such a way that the child will appreciate its value and be able to practice it intelligently in the home. We chose animal experiments to stimulate an interest in the effect of good and poor nutrition. The Home Economics and Physical Education Departments coöperated with the City Health Department in conducting these experiments.

Our purpose in conducting these experiments has been to show the effect of special foods on the growth and health of young rats and thereby stimulate in the child an interest in his own well-being. The foods and drinks used represented some of those generally used by the children of this city—coffee, candy, milk, lettuce and soft drinks.

White rats, cages, a pair of accurate scales measuring in grams, and other necessary equipment were provided. The Home Economics Department seemed to be the logical place for the rats to be kept, because of the accessibility of food and water and because of that department's interest in nutrition.

A list of instructions was placed in the hands of each home economics teacher, relative to the kind and amount of each food to be used for each group of rats per day. Their basic food consisted of white corn meal and salt, (5 cupfuls of corn meal to 1 tablespoonful of salt). The "special" foods: milk, coffee, soft drinks, sugar and lettuce, were fed in amounts that could be disposed of readily, only one "special" food being used at a time.

RATION

Coffee	2	tblsp	per	rat	per	day
Soft drink	2	"	"	"	"	"
Milk	2	"	"	"	"	"
Lettuce	About 15	gm	per	rat	per	day
Candy or sugar	3	"	"	"	"	"
Meal	All they could use					

Once each week each group of rats was weighed. These weights were recorded on posters (made for the purpose), and kept on the bulletin board in the hall, where all of the children could read them.

LITTER 93 gm 125 gm MILK 86 gm. 166 gm.

COFFEE 93 gm 94 gm MEAL 85 gm. 106 gm.

SUGAR 99 gm 91 gm MILK 86 gm. 166 gm.

SOFT DRINKS 100 gm 91 gm. MILK 86 gm. 166 gm.

Just to show the effect of food on the growth and health of young rats would not be so important in itself; but the child quickly applied to himself what he had learned. One child remarked: "Now I see the value of this; you are showing us what good nutrition will mean to us." The interest was keen and the value of the experiment was proved when the children began to change their habits in eating. In many

instances milk took the place of coffee, candy was reserved for after meals, lettuce and salads became more popular, and fewer soft drinks were purchased.

The following graphs represent the weight in grams, per week, for

WEIGHT IN GRAMS PER WEEK FOR PAIR OF RATS

the pair of rats. The rats' response to the change in food is also represented on the graph. Note the immediate increase in weight when milk is added and the decline in weight when coffee is added.

All of the rats were 4 weeks old when the experiment began. They were from the same family and had the same treatment. At the end of 6 weeks on "special foods," the pictures were made. The weights are for two rats of like experiment, made at the beginning and at the end

of the 6 weeks' experiment. (Only one rat from each experiment is shown in the pictures, that a comparison may be made, with one fed on milk or on some other food.)

Animal experimental work stimulates an interest in personal well-being.

A Heating Factor Which May Explain the Winter Cold

IN a restricted, but at the same time, the most generally accepted sense, ventilation may be defined as the maintenance of healthful atmospheric conditions. A most important factor among these conditions is that of temperature. Perhaps not enough attention has been given to the source and nature of the heat which is customarily used in maintaining a comfortable temperature in the winter season. If there is something in the matter of ventilation, and particularly heating, that predisposes to the "winter cold," as is commonly asserted, may it not be the usual forms of heating themselves—hot air furnaces, steam, hot water, coal stoves, and the like, and, because these emit energy from but one end of the spectrum, the dark heat rays"? Such sources of heat are, of course, devoid of the shorter visible and ultra-violet rays which characterize sunshine and daylight, the health giving and disease resisting qualities of which are universally admitted. In short, perhaps the "winter cold" is due to too constant exposure to a "partial spectrum"—the long rays. A truly radiant source of heat to maintain the room temperature, such as the glowing fireplace, the radiant electric coil, the radiant type of gas stove, etc., or the campfire of old, all of which supply a quite complete spectrum—comparable to the sun's rays at sea level—might be the answer to the "winter cold," or, it might be possible to secure the beneficial results by using the present sources of heat for bringing the room temperature up to 50°-60° F. and using the "radiant type of heater" for the balance necessary for comfort.

To prove or disprove this theory, would require, it seems to the writer, a considerable group of persons, preferably of all ages, and under 24-hour daily control, so far as interior existence is concerned, for a period of perhaps 5 years. Retention institutions, or perhaps founding homes, with their attendants, suggest themselves as proper places for investigating the subject, where some of the inmates could be left under the present mode of heating, and the others required to depend upon heat from a glowing radiant source for comfort.—Emery R. Hayhurst, M.D., Ohio State University.

University Degrees in Public Health*

THE report of the committee consists of two tables presenting data concerning candidates for and recipients of public health degrees during the year 1927, and replies to an inquiry sent to schools granting the Doctor of Public Health degree.

TABLE I

NUMBER OF STUDENTS ENROLLED AND PUBLIC HEALTH DEGREES CONFERRED IN 1927 IN COURSES REQUIRING AT LEAST ONE YEAR OF RESIDENCE AND LEADING TO A PUBLIC HEALTH CAREER

School	Degree	No. Enrolled 1926-1927	No. of Degrees Conferred 1927

THE HONORARY DOCTOR OF PUBLIC HEALTH DEGREE

Believing that the Doctor of Public Health degree should not be granted as an honorary degree but that it should be granted only upon the completion of a definite and adequate program of training, the committee has sought to ascertain the attitude of the various schools. In reply to inquiries sent to all schools which have granted the Doctor of Public Health degree, the following conditions have been reported:

Harvard University, Johns Hopkins University, Massachusetts Institute of Technology, University of California and Yale University give the Doctor of Public Health degree in course, but they have never given an honorary Doctor of Public Health degree and the faculty representatives upon this committee state that it is contrary to the policy of these institutions to do so. The University of Michigan gives the Doctor of Public Health degree in course, but it has discontinued by faculty action the policy of granting the honorary Doctor of Public Health degree.

In Canada, at Queen's University, McGill University, University of Montreal, University of Toronto and University of Western Ontario, the Diploma in Public Health is offered as a degree in course, but never as an honorary degree.

Detroit College of Medicine and Surgery, University of Georgia, and University of Pennsylvania offer the Doctor of Public Health degree in course and have also given it as an honorary degree. The committee representatives from these schools state that the schools are opposed to granting the honorary Doctor of Public Health degree frequently or as a routine procedure, but they believe the schools are not willing as yet to surrender the occasional privilege of giving it to exceptional individuals.

The other institutions which offer public health training have not up to the present time offered the Doctor of Public Health degree.

The Continuous Clinic

THE continuous clinic has been carried out in small towns and rural communities of Geary County, Kan., with apparent satisfaction to all concerned—the underprivileged child, the profession and those contributing funds.

A limited fund for this health work was obtained by means of the Christmas Seal sale. When the physicians, dentists and optometrists were approached for their coöperation, without exception they offered their services. Following the conclusion of preliminary arrangements two blanks were printed and distributed.

The method for locating worthy and needy patients for the clinics is simple. Whenever a school nurse, teacher or other responsible person discovers a child who is in need of a tonsillectomy, spectacles or dental work, or a nutritional case where the economic condition of the family does not permit proper provision for the child, she fills out Blank 1, which states that the child is in need of dental, throat or eye work, and is financially unable to take care of it. Upon receipt of Blank 1 by the director of the clinic, Blank 2 is sent to the parents with the request that they fill it out and return to the clinic director. Blank 2 is really a contract between the doctor or dentist and the child. Corrective work may be done then or at a time more convenient to patient and physician or dentist. When the service is completed the blank indicating the work that has been done is returned with the charges. The charges are paid from the fund, which closes the case.

This plan for the Continuous Eye, Throat and Dental Clinic which has been in operation in Junction City for more than a year has advantages over other plans tried, because,

1. In a small community there are seldom enough cases to require a special day set apart for that purpose.
2. It gives us time to inquire and ascertain that the child is really in need of the work and is unable to pay for it from the family income.
3. It enables the doctor, dentist or eye man to coöperate to better advantage and still not absent himself from his office for several hours at a time.
4. The child going to the doctor by regular appointment is often saved from the feeling of pauperism.
5. This plan avoids the criticism expressed by some that public clinics are a direct step toward obligatory state medicine—R. B. Stafford, M.D., Health Officer, Geary County, Junction City, Kan.

FIFTY-SEVENTH ANNUAL MEETING

ONCE each year in an unbroken series, from 1872 to 1927, the American Public Health Association has brought together at its Annual Meeting the public health profession of the North American Continent.

The 57th Annual Meeting which will be held at Hotel Stevens, in Chicago, October 15-19, 1928, promises to equal or exceed any previous meeting in size, interest and scientific value. Not since the Semi-Centennial in 1921 has an Annual Meeting had such an auspicious setting. The program, which is printed in this issue, is one of great merit, and exceeds in variety those of previous years.

The Local Committee has planned so generously for trips of scientific and general interest, for entertainment for delegates, and especially for ladies, that it has been impossible to give more than an outline of their plans in the space available in the JOURNAL.

This Annual Meeting of the American Public Health Association will be enriched by the presence of many members of nine other organizations. The American Child Health Association will hold its Annual Meeting jointly with us. Simultaneously there will be held the Annual Meeting of the Illinois Conference of Health Officers and Public Health Nurses. There will be meetings also of the International Association of Milk and Dairy Inspectors, American Social Hygiene Association, Conference of State Sanitary Engineers, Conference of State Laboratory Directors, Women's Foundation for Health, Association of Women in Public Health, Association of School Physicians.

It is only at infrequent intervals in the course of the public health movement on the North American Continent that there is brought together at one time and in one place such a galaxy of leaders. No stretch of the imagination is needed to picture the significance of such

an event. The younger members of the profession will be able to see, hear and meet those more experienced leaders whom they have previously followed only through the printed page. Old friendships will be brought up to date and new ones will be made. The isolated worker who has been fighting single-handed will give and gain strength by his presence.

The older leaders will be encouraged in their hopes by seeing many young recruits. There will be much of technic—purely professional patter—but meaningful. There will also be let loose those forces more difficult of measurement which bind together those facing a common task.

Will you be there?

PRESENT STATUS OF CHEMICAL FOOD PRESERVATIVES AND COLORING MATTERS

THE addition of chemical preservatives to foods has been a matter for hot discussion over many years, and in this country has even played a part in politics. During the World War regulations were relaxed, and until recently no authoritative statement of the laws in various countries has been available. We owe to The Office International D'Hygiène Publique a report which gives the regulations in eighteen countries, Germany being the most important one for which there are no data.

It is possible to give only a general summary, as the preservatives allowed in different countries vary considerably, and in some, the United States for example, there are general laws carried out by regulations. In this country the law prohibits the use of any poisonous or injurious substances which may affect the healthfulness of the food, certain chemicals, such as salicylic and boric acids, the borates and formaldehyde being forbidden. In the case of foods for use on ships the external application of certain preservatives is allowed, but they must be such as can be easily removed mechanically, or by soaking in water, or by other processes, and a label must be attached giving directions for this.

The artificial coloration or decoloration of foods has reached the point of being a fine art. A great variety of coloring matters is allowed, and on this account the regulations regarding this matter are much more inexact than are those concerning preservation. For the most part, the coloring matters used at present are coaltar derivatives, and in the United States one is required to use materials which have been certified by the proper officers. It will be remembered that fairly

recently the use of nitrites instead of nitrates has been allowed to give the red color to corned beef and similar products.

It is interesting to note that formaldehyde is not recommended by any country, and its use is specifically forbidden in many, including England, Canada, Australia, the United States, Bulgaria, and France. New Zealand, Sweden, Switzerland, England, Bulgaria, and the United States prohibit the use of boric acid or its compounds, while Canada, France, and some other countries allow it in such foods as butter, condensed milk, cream, and margarine, under restriction as to the amount. The United States, England, Bulgaria, and France prohibit the use of salicylic acid, while a number of other countries allow its use in minimum amounts. Benzoic and sulphurous acids are allowed more widely than any other preservatives. In England and Wales these are the only preservatives permitted and their use is restricted to certain foods and within definite limits as to quantity. France forbids the use of benzoic acids and benzoates.

In studying the bulletin¹ one is impressed by the fact that there is greater uniformity in the countries which have reported than there was a few years ago. Certain preservatives are quite generally prohibited or their use limited, and there is considerable uniformity in the sanction of certain preservatives for the same foods.

The matter is one about which there is some room for difference of opinion. The safe rule is to allow only those preservatives which, after extensive trial or prolonged use, have been proved harmless. In general, chemical preservation should be restricted as far as possible, especially in view of the almost universal refrigeration which is now available. The addition of preservatives makes it possible to put foods on the market which are unfit for use, and advantage is taken of this fact by some manufacturers. It may be said with certainty that the more nearly foods are used in their fresh and natural condition, the better for the consumer, the less the danger of injury by poisoning, acute or chronic, and the surer we are of not destroying certain valuable properties belonging naturally to the foods.

TULAREMIA

THIS disease, which is now attracting considerable attention, was first described by McCoy, in 1911, as "a plague-like disease of rodents," having been found in the routine examination of these animals carried on in San Francisco. The causative organism was named *Bacterium Tularense*.

In 1919 and 1920, Dr. Francis, of the U. S. Public Health Service, found the same disease in Utah, gave it its present name, and showed that it was spread by the deer fly. In that section it was known as "deer fly fever." It is called by market men, "rabbit fever," owing to the fact that in the East, at least, it is kept alive in wild rabbits, and they are the chief source of infection for man. In this section, November, December and January are the months in which the majority of cases occur, since vast numbers of these animals are killed and sold for food.

The germ was isolated in 1912 by McCoy and Chapin. Spleens and livers of infected animals contain the germs.

The disease is extremely infectious and every laboratory man who has worked with the germ in this country and in England has contracted it. In nature, the deer fly (*Chrysops discalis*) and the wood tick (*Dermacentor andersoni*) are apparently the chief agents in conveying the disease from animal to man. Under laboratory conditions, the mouse louse, the bedbug, the stable fly and the squirrel flea have been shown to be capable of transmitting the germ. Ticks harbor the infection in their feces, their circulatory fluid and in the epithelial cells of their intestinal tract. The germ is able to survive the winter in the tick, and may be transmitted from stage to stage in the development of the tick, and is transmitted through the egg to the next generation. Even the handling of an infected tick appears to produce infection, though the sucking period is the dangerous time. Certain flies seem to carry the infection for four days at the longest. The deer fly is commonly found on horses in Utah from May to September. The woodtick is found in Montana and adjoining states, and is active in March, April, May and June. In other parts of the country, the ordinary wild rabbit seems to be the important source of infection. West of the Mississippi River, the jack rabbit is the chief agent in spreading the disease. It is used for bait, the feeding of chickens, dogs and foxes, as well as for the table.

During the last few years, a number of cases have been reported from states in the East. Most of these have been found in and near Washington, D. C., probably due to the activity of Dr. Francis in that area. Twenty-two cases have been recorded, and of the patients, 17 have been engaged in dressing rabbits for the market.

The disease is not very fatal, the mortality being about 4 per cent. Among 420 recorded cases, 17 deaths have occurred, but these include only cases reported to the U. S. Public Health Service, which up to the present has been the body which has shown the greatest activity in studying the disease and its epidemiology. Cases have been

reported from 37 states, the District of Columbia and Japan, but none from the 9 New England States, the only area in this country known to be free.

There are two general types of the disease—one in which the glands become enlarged and painful, and are apt to go on to suppuration, and the other, seen in laboratory workers, which resembles typhoid fever. Fever, running as high as 104° , is always a symptom, and persists for from 2 to 3 weeks. The diagnosis is confirmed by agglutination with a known culture.

Special precautions must be taken in the diagnosis by agglutination, similar to those for typhoid fever. The reaction is absent during the first week, but comes on in the second week, often in low titer, though occasionally it will show agglutination in a dilution of 1 to 500 or even higher. The maximum agglutination appears during the third and fourth weeks. Agglutination in dilutions of 1 to 1200 is not uncommon, and takes place even up to 1 to 2500. At least 0.5 c.c. of blood is required, and more than this quantity is desirable. The reaction is very persistent, lasting for five years or more. No preservatives other than pure neutral glycerin should be added.

The disease has never been observed in domestic animals. There is no special treatment, no preventive vaccine, no curative serum, and no drug has been found which has any specific effect.

Fortunately the germ is easily killed in cooking, 133° F. being sufficient. Those who dress rabbits for market should wear rubber gloves, and since one attack protects against another, immune persons should be employed in this work as far as possible. Freezing for 30 days will render dead rabbits free from danger. Market inspection is of little value since the organs which carry infection—the liver and spleen—have been removed in dressing. Health officers and physicians who are called to cases which are not easy of diagnosis should remember to look for tularemia.

TERMINAL DISINFECTION

THIS subject has not been much discussed in the United States for some years past. As early as 1912, Charles V. Chapin, M.D., for the first, as far as we are aware, showed the doubtful value of terminal disinfection both as an abstract proposition and as actually practiced. He discontinued terminal disinfection for certain diseases in the City of Providence as early as 1905. In 1914 it was discontinued in certain boroughs of New York City, and in Manhattan on January 1, 1915. Convincing figures were collected by Dr. Chapin, and later by the

authorities in New York, to show that the discontinuance of terminal disinfection had not led to the increase of contagious diseases. An enormous amount of money was thereby saved without detriment to the public health. While other cities have followed suit, the practice is still continued in many places, and without doubt has a strong hold on the public as well as the profession.

The matter was called to the public attention last year by a masterly presentation by Dr. Carlos Chagas,¹ and more recently by a translation and reproduction of his article in England.² In this country it would seem almost unnecessary to comment upon this subject except for the widespread sale of disinfectants, good, bad, and indifferent, and the frequent advertisement of alleged new discoveries of germicidal substances, though we believe that these appear much less frequently than a few years ago, when scarcely a week passed without some alleged discovery. The great majority of these preparations were coal tar products, and their relative value depended upon the amount of a few active substances which they contained, and upon their miscibility and solubility. One has only to consult the table worked out by the late Dr. McClintic³ to become convinced of the lack of value of many of these preparations. The names of them often indicated the known chemical upon which their value, such as it was, depended. It was always cheaper and better to use the chemicals, which were easily obtainable from wholesale houses in greater or less degrees of purity.

A survey of disinfection as practiced in various countries has convinced Dr. Chagas that the procedure was almost always useless, based on incorrect ideas, and the results not commensurate with the expense, conclusions which had been reached by Dr. Chapin and others many years ago. While these procedures have had a certain educational value, and have allayed the fears of nervous people, their actual value has been slight. Unfortunately, if disease germs are scattered through premises in which contagious diseases have been treated, it is impossible in most cases to locate them, or to influence them through any "process of camouflage," as it has been called by Dr. Balfour. It has been wisely taught for some years that a properly cared for case of contagious disease should not be allowed to contaminate the surroundings. Dr. Chagas stresses the point that the great objection to terminal disinfection is not so much its uselessness as a preventive measure, but the fact that it seems necessary. The real danger from a contagious disease lies in the excretions from the body. Disinfection of the sputum, excreta, and pathological discharges, should be carried out during the progress of the case rather than after death or recovery,

since whatever danger is possible has already occurred and late disinfection cannot do away with it.

Patients suffering from communicable diseases must be protected during their illness. Clothing, bedding, towels, utensils, and all other objects which are used or which come into contact with the patient should be promptly disinfected. The high value of hot water and soap, sunshine and fresh air must not be forgotten. It is expensive and impracticable to increase the rigor of terminal disinfection to a point where it will be absolutely effective.

Dr. Chagas takes up in detail a number of contagious diseases to demonstrate his ideas and one cannot read his arguments without being convinced of the soundness of his reasoning, backed up as it is by an extensive experience.

As Americans, we take pride in the fact that, as far as our knowledge goes, Dr. Chapin preceded all others in these ideas and in the practical demonstration of their soundness; but we welcome the clear presentation given by Dr. Chagas in corroboration of what we have believed and practiced for a number of years.

CHILD WELFARE IN CHICAGO

HEALTH workers who attend the 57th Annual Meeting in Chicago in October will have an exceptional opportunity to see the results, in child welfare work, of earnest coöperation between private social agencies and the public officials of that city, especially the Department of Health. Child welfare activities in Chicago, as in other large cities have grown to include a wide and varied range of endeavor. The Chicago Local Committee is making arrangements so that those who attend the convention may see the outstanding work of the Chicago Health Department, the Infant Welfare Society, the Visiting Nurses' Association, the Elizabeth McCormick Memorial Fund, the Illinois Institute for Juvenile Research, the Juvenile Court and the Juvenile Protective Association, together with that of other child welfare agencies.

Child Welfare activities in Chicago may be grouped as prenatal, infant welfare, preschool, and school. Chronologically, work for the school child was the first to be started. In 1896, medical inspection of school children for contagious diseases was instituted. In 1908, this was expanded to include physical examinations for defects, and a corps of nurses was added to do the follow-up work in getting these defects corrected.

At the present time, with the exception of special nutrition work being done by the Elizabeth McCormick Memorial Fund and tuberculosis prevention by the Municipal Tuberculosis Sanitarium, all health activities in the public and parochial schools are carried on by the Department of Health. The school physicians of this department work in three groups, as follows:

One hundred and twenty-two physicians visit the schools daily to inspect for

contagious diseases; each physician is permanently assigned to a district and is held responsible for the schools within that area. Fifty-two physicians conduct thorough physical examinations of the children in the kindergarten and primary grades, and routine reinspections of the 6th and 8th grade children graduating into the junior and senior high schools. Ten to 20 physicians are assigned to the administration of toxin-antitoxin, making Schick tests and vaccinating against smallpox. During the 5 school days each week, they spend their time in the schools, but on Saturdays they render this service to infants and preschool children at the infant welfare stations and other health and social centers. The nursing staff assists these physicians in all the above mentioned activities and carries out the necessary follow-up work.

Defects discovered by physicians conducting physical examinations are corrected by private physicians, dispensaries and such special agencies as the Illinois Society for the Prevention of Blindness, The Chicago Heart Association and many others. Dental care is provided through the private dentists at 12 dental clinics maintained in the schools by the Department of Health; the Municipal Tuberculosis Sanitarium at the 8 dispensaries; the children's dental clinic at the Cook County Hospital and the clinics of the dental colleges.

A discussion of the health work in the schools would not be complete without mentioning the home hygiene courses given to grammar school pupils of the parochial schools by the American Red Cross and the Chicago Department of Health; through these classes 60,000 boys and girls have received instructions in home health, and, to some extent,

home care of the sick has been taught.

After the inauguration of health work in the schools, the next large child health effort had its beginning in 1899, when Dr. A. R. Reynolds, then Commissioner of Health, assigned 73 volunteer physicians during the hot weather to mother and infant care in the thickly populated and poor sections of the city.

In 1902, the Milk Commission began and continued for 8 years to prepare and distribute to needy mothers clean modified milk.

Infant welfare as it is today had its beginning in 1909 in a coöperative movement of the United Charities, the Visiting Nurse Association and the Department of Health and including, of course, the work of the Milk Commission already existing, to lower further the infant mortality rate. Important as this work was, and though it accomplished much, it was decided that one organization would be more effective, and consequently all baby welfare agencies were reorganized into a single private agency,

Chicago Herald Examiner

CEREAL TASTES MIGHTY GOOD AT THE PRESCHOOL CONFERENCE

the Chicago Infant Welfare Society. Today this organization conducts 23 stations, for the most part situated in the poverty area surrounding the "Loop," where the infant mortality rate is highest.

In 1913, cooperating with the Infant Welfare Society, the Department of Health entered this field and is now conducting 22 stations in the more outlying districts outside the zone of activity of the Infant Welfare Society. By mutual agreement, each organization confines its work to its own districts and a mother is allowed to transfer from one district to another only by special permission.

These early activities in infant care proved their effectiveness by markedly lowering the infant mortality rate. However, it was found that before this rate could be lowered further the prenatal, natal and preschool periods must also be given careful attention, as the death rate in these periods remained un-

changed. Consequently, both the Infant Welfare Society and the Department of Health expanded the station work to include prenatal and preschool care. The society now has 10 prenatal and 17 preschool conferences. The Department of Health has 6 prenatal and 14 preschool conferences. As the physical care of the child has been perfected, a realization of his mental needs has developed; to meet this need the Infant Welfare Society has added a trained psychiatric social worker to its staff to aid in discovering and caring for behavior problems among children.

With the recently aroused interest in the preschool child, especially from the standpoint of behavior, the nursery school has come into vogue. There are three remarkable examples of this type of education in Chicago, namely the University of Chicago Coöperative Nursery School, The Nursery School of the Franklin Public School and the Mary Crane Nursery School at Hull House.

Beside the activities of the Infant Welfare Society and the Department of Health in the prenatal field, much work is being done by other organizations. The Chicago Community Trust, in 1922, in their survey of prenatal care in Chicago found 32 organizations conducting prenatal conferences. Outstanding is the work of the Chicago Lying-in Hospital and its 2 out-departments. All the medical schools and many of the hospitals conduct prenatal conferences.

With so many agencies at work in one field of endeavor, it is inevitable that there is much dovetailing and overlapping and even duplication of effort. Much of this is now eliminated by the clearing of all cases through the Social Service Exchange. Mutual understanding and coöperation of the agencies are promoted by the Chicago Council of Social Agencies. As an example of the coöperative effort, the Mary Crane Nursery School at Hull House deserves

special mention. In this project, handling about 53 school children, the educational work is carried on by the National Kindergarten and Primary College of Evanston, the medical and nutritional work by Chicago Infant Welfare Society, the mental hygiene by the Illinois Institute for Juvenile Research, the dental work by the Chicago Department of Health and the social work by the United Charities.

A final word must be said of the outdoor facilities for play and recreation with which Chicago is so wonderfully supplied. In all parts of the city are small parks and playgrounds with organized and supervised activities. There are many miles of beach along the lake shore and thousands of acres of forest preserves just outside of the city limits. Certainly, these features are no small adjunct in aiding these other human agencies in maintaining a high standard of child welfare in this community.

LEARNING FATHERCRAFT AT ONE OF THE RED CROSS HOME NURSING SCHOOLS

PRELIMINARY PROGRAM OF THE FIFTY-SEVENTH ANNUAL MEETING

AMERICAN PUBLIC HEALTH ASSOCIATION

Chicago, Ill. October 15-19, 1928

DELEGATES are urged to consult the final program at the meeting for information as to the exact time and place of sessions. All meetings will be held in the Hotel Stevens. Morning sessions will be at 9:30; luncheon sessions at 12:30; afternoon sessions at 2:30; dinner sessions at 6:30; and evening sessions at 8:30.

GENERAL SESSIONS

First Session—Monday Evening

Addresses of Welcome.

Address of the President of the American Public Health Association.

HERMAN N. BUNDESEN, M.D., Health Director, Chicago Sanitary District, Chicago, Ill.

Address of the President or of a Representative of the American Child Health Association.

Second Session—Wednesday Evening

Report of the Committee on Dairy Products. WILLIAM H. PARK, M.D., Director Health Department Laboratories, New York, N. Y.

Organizations for the Care of the Sick. W. S. RANKIN, M.D., Duke Endowment, Charlotte, N. C.

How To Use Effectively Civic Groups in Promoting Health Programs. E. L. BISHOP, M.D., State Health Commissioner, Nashville, Tenn.

International Health. FRANK G. BOUDREAU, M.D., Health Section, League of Nations, Geneva, Switzerland.

Banquet—Thursday Evening

Program in Charge of Local Committee

SPECIAL SESSIONS

CANCER

Special Session—Wednesday p. m.

Program arranged by the President

COMMITTEE ON TRAINING AND PERSONNEL

Dinner Session—Wednesday

(This is an open meeting of the committee to which everyone is invited.)

Minimum Training For All Persons Entering the Public Health Profession.

Presiding, C. E. TURNER, DR.P.H., Professor Department of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, Mass.

Discussion. JOHN SUNDWALL, M.D., Director, Division of Hygiene, Public Health and Physical Education, University of Michigan, Ann Arbor, Mich.

EPIDEMIOLOGY

Special Session—Thursday p. m.

The Age Distribution in Milk-borne Outbreaks of Scarlet Fever and Diphtheria. EDWARD S. GODFREY, JR., M.D., Director, Division of Communicable Disease, State Department of Health, Albany, N. Y.

A Further Epidemiological Study of Undulant Fever in Michigan. PAUL F. ORR, M.D., Commissioner of Health, Toledo, O.

Epidemiological Studies of 83 Cases of B. Abortus Infection. A. V. HARDY, M.D., State Epidemiologist, Iowa City, Ia.

A Series of Typhoid Cases Infected per Rectum. CLIFFORD R. HERVEY, M.D., District State Health Officer, Oswego, N. Y.

Water-borne Epidemics of Diarrhea in Illinois. THOMAS G. HULL, PH.D., Diagnostic Laboratory, State Department of Public Health, Springfield, Ill., LLOYD ARNOLD, M.D., Associate Professor of Bacteriology and Preventive Medicine, University of Illinois College of Medicine, Chicago, Ill., and HARRY F. FERGUSON, Sanitary Engineer, State Department of Health, Springfield, Ill.

An Epidemiological and Bacteriological Study of Epidemic Meningitis in Chicago. ALTON S. POPE, M.D., and JOHN L. WHITE, M.D., Department of Health, Chicago, Ill.

Racial Distribution and the Death Rate of Diphtheria in New York City. HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y. (*Stereopticon Illustration*.)

Discussion. EDWARD S. GODFREY, JR., M.D., State Department of Health, Albany, N. Y.

JOINT SESSIONS

HEALTH OFFICERS AND THE AMERICAN SOCIAL
HYGIENE ASSOCIATION

Joint Luncheon Session—Monday

MUNICIPAL CONTROL OF VENEREAL DISEASES

Chairman, C. HAMPSON JONES, M.D., Commissioner of Health, Baltimore, Md.

Discussion. HENRY F. VAUGHAN, D.P.H., Commissioner of Health, Detroit, Mich., WALTER M. BRUNET, M.D., Secretary, Social Hygiene Committee, New York Tuberculosis and Health Association, New York, N. Y., EARLE G. BROWN, M.D., Secretary, Kansas State Board of Health, Topeka, Kan., and ALBERT PFEIFFER, M.D., Director, Division of Social Hygiene, State Department of Health, Albany, N. Y.

LABORATORY AND FOOD, DRUGS AND NUTRITION SECTIONS

Joint Session—Monday p. m.

Colon-Aerogenes Group in Milk. EDMUND K. KLINE, DR.P.H., Jefferson County Board of Health, Birmingham, Ala.

Recent Observations upon the Detergent Action of Dairy Washing Compounds. MILTON E. PARKER, Technologist, Philadelphia Dairy Products Company, Inc., Philadelphia, Pa.

Heat Resistant and Heat Loving Bacteria in Pasteurized Milk. ROBERT S. BREED, PH.D., Chief in Research, Agricultural Experiment Station, Geneva, N. Y. (*Stereopticon Illustration.*)

Failure of Standard Method for Visible Dirt in Milk to Meet Connecticut Requirements: Need for New Standard for Market Milk. FRIEND LEE MICKLE, M.S., Director, Bureau of Laboratories, State Department of Health, Hartford, Conn. (*Stereopticon Illustration.*)

Discussion. Opened by ROBERT S. BREED, PH.D., Chief in Research, Agricultural Experiment Station, Geneva, N. Y.

Viability of *B. Typhosus* in Cheddar Cheese. E. M. WADE and LEWIS SHERE, State Department of Health Laboratories, Minneapolis, Minn.

CHILD HYGIENE AND PUBLIC HEALTH NURSING SECTIONS WITH AMERICAN CHILD HEALTH ASSOCIATION

Joint Session—Tuesday a. m.

MATERNAL MORTALITY

Presiding: FRED L. ADAIR, M.D., Professor of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minn.

Report of the American Public Health Association, Child Hygiene Section, Committee to Report on the Status of Maternal and Infant Mortality. *Chairman,* JULIUS LEVY, M.D., Consultant, Bureau of Child Hygiene, State Department of Health, Trenton, N. J.

Discussion

Report of Sessions on Maternal Mortality in the Conference of State Directors of Maternity and Infancy Work, U. S. Children's Bureau, April, 1928. BLANCHE M. HAINES, M.D., Director of Division of Maternity and Infant Hygiene, U. S. Children's Bureau, Washington, D. C.

Discussion. LILLIAN R. SMITH, M.D., Director, Bureau of Child Hygiene and Public Health Nursing, State Department of Health, Lansing, Mich.

Report of Section of Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association. *Chairman,* CARL H. DAVIS, M.D., Chairman, Section of Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association, Milwaukee, Wis.

Discussion. WILLIAM C. DANFORTH, M.D., Fellow, American Gynecological Society, Evanston, Ill.

Report of Maternity Center Association Experiences in Tioga County, N. Y. HAZEL CORBIN, R.N., General Director, Maternity Center Association, New York, N. Y.

Discussion. GUY S. CARPENTER, M.D., Chairman of Public Health Committee of Tioga County Medical Society, Waverly, N. Y.

HEALTH OFFICERS, PUBLIC HEALTH NURSING AND CHILD HYGIENE SECTIONS WITH THE AMERICAN CHILD HEALTH ASSOCIATION

Joint Session—Tuesday p. m.

Studies on Infant Mortality. GEORGE T. PALMER, D.P.H., Director, Division of Research, American Child Health Association, and DOROTHY F. HOLLAND, PH.D., Staff Associate, American Child Health Association, New York, N. Y.

Discussion. PHILIP VAN INGEN, M.D., Professor of Clinical Pediatrics, Columbia University, New York, N. Y.

General Discussion

Pediatric Service in City Health Department Centers Provided by Medical Schools in Boston. HAROLD C. STUART, M.D., Department of Child Hygiene, School of Public Health, Harvard University, Boston, Mass.

Discussion. WILLIAM H. PETERS, M.D., Commissioner of Health, Cincinnati, O.

General Discussion

Result of the National Congress of Parents and Teachers 1927 Summer Round-up of Preschool Children. MARY E. MURPHY, Director, Elizabeth McCormick Memorial Fund, Chicago, Ill.

General Discussion

SYMPOSIUM ON PRESCHOOL HEALTH SUPERVISION

In the Small Towns and Rural Areas. ELIZABETH M. GARDINER, M.D., Director, Division of Maternity, Infancy and Child Hygiene, State Department of Health, Albany, N. Y.

In a Small City. B. K. KILBOURNE, City Health Officer, Fargo, N. D., and LESTER J. EVANS, M.D., Child Health Demonstration Committee, New York, N. Y.

In a Limited Area of a Large City. GRACE L. ANDERSON, R.N., Director, East Harlem Nursing and Health Service, New York, N. Y.

In a Large City. By a Voluntary Agency Acting for the City Health Department. SARA B. PLACE, R.N., Superintendent, Infant Welfare Society, Chicago, Ill.

PUBLIC HEALTH ENGINEERING AND LABORATORY SECTIONS

Joint Session—Friday a. m.

SYMPOSIUM ON RESEARCH IN SEWAGE AND INDUSTRIAL WASTE DISPOSAL

Can Garbage be Digested with Settling Sludge? GORDON M. FAIR, Assistant Professor of Sanitary Engineering, Harvard University, Cambridge, Mass. (*Stereopticon Illustration.*)

Some Biochemical Factors in Sewage and Sludge Treatment. WILLEM RUDOLFS, Chief, Department of Sewage Disposal, Agricultural Experiment Station, New Brunswick, N. J.

Discussion. 20 minutes

Comparison of Stream Flow and Diffused Air Aeration in Purification of Packing House Wastes. MAX LEVINE, PH.D., Professor of Sanitary Bacteriology, HARRY N. JENKS and GEORGE NELSON, Iowa State College, Ames, Ia.

The Relation of Sulfite Reducing Bacteria in Sewage. FRANK E. GREER, Principal Bacteriologist, Department of Health, Chicago, Ill.

Discussion. 20 minutes.

Need for Coördination of Research in Sewage and Industrial Wastes. CLARENCE M. BAKER, Engineer, American Paper and Pulp Association, New York, N. Y.

CHILD HYGIENE AND PUBLIC HEALTH EDUCATION SECTIONS WITH THE AMERICAN CHILD HEALTH ASSOCIATION

Joint Session—Friday a. m.

SCHOOL HEALTH EDUCATION

EFFORTS TO DATE TO DEFINE OBJECTIVE STANDARDS IN HEALTH EDUCATION

A Review of School Health Work. JAMES F. ROGERS, M.D., DR.P.H., Chief, Division of Physical Education and School Hygiene, Bureau of Education, Washington, D. C.

Discussion. This paper will be discussed through progress reports of present-day school health studies, as follows:

Health Education Studies Carried on by the University of Michigan. JOHN SUNDWALL, M.D., Director, Division of Hygiene, Public Health and Physical Education, University of Michigan, Ann Arbor, Mich.

Educational Tests in American Child Health Association School Health Study. RAYMOND FRANZEN, PH.D., Research Director, School Health Study, American Child Health Association, New York, N. Y.

LABORATORY

First Session—Tuesday a. m.

Report of the Committee on Training and Personnel—*Laboratory Section Representative*, JOHN F. NORTON, PH.D., Director of Laboratories, Department of Health, Detroit, Mich.

Standardization of the Wassermann Test. Report of Progress for 1928. (Report of the Committee on Standard Methods.) *Referee*, RUTH GILBERT, M.D., State Department of Health, Albany, N. Y.

Report of the Committee on Standard Methods. *Chairman*, E. O. JORDAN, PH.D., University of Chicago, Chicago, Ill.

Report of the Committee on Abstracts in the Journal. *Chairman*, C. C. YOUNG, D.P.H., Director, State Department of Health Laboratories, Lansing, Mich.

SYMPOSIUM ON UNDULANT FEVER

- B. abortus in Milk and its Relation to Undulant Fever. CHARLES M. CARPENTER, PH.D., New York State Veterinary College, Diagnostic Laboratory, Cornell University, Ithaca, N. Y., and MERRILL J. KING, M.D., Director, John R. Hegeman Laboratory, Metropolitan Life Insurance Company, Mt. McGregor, N. Y.
- Further Observation on Human Infection with B. abortus. JAMES G. McALPINE, PH.D., Storrs Agricultural Experiment Station, Storrs, Conn., and FRIEND LEE MICKLE, M.S., Director, Bureau of Laboratories, State Department of Health, Hartford, Conn.
- Studies on Blood for Undulant Fever, Endemic Typhus and Tularemia. WILLIAM S. LITTERER, M.D., Director, State Department of Public Health Laboratories, Nashville, Tenn.
- The Differentiation of Species of the Genus Brucella. I. F. HUDDLESON, D.V.M., Michigan State College, East Lansing, Mich. (*Stereopticon Illustration.*)
- Study of Methods for Isolation of B. abortus. RUTH GILBERT, M.D., M. B. COLEMAN and W. M. GROESBECK, State Health Department Laboratories, Albany, N. Y.
- Unsolved Undulant Fever Problems. ALICE C. EVANS, Hygienic Laboratory, Washington, D. C.

Second Session—Thursday a. m.

- A Study of the Effect of Calmette's B. C. G. Vaccine on Experimental Animals. MERRILL J. KING, M.D., Director John R. Hegeman Laboratory, Metropolitan Life Insurance Company, Mt. McGregor, N. Y.
- 2500 Microscopic Slide Precipitation Tests and Wassermann Tests with Same Antigen with Clinical Comparison. BENJAMIN S. KLINE, M.D., S. LITTMAN and M. G. BOWMAN, Mt. Sinai Hospital, Cleveland, O.
- Use of Toxoid-Antitoxin Floccules in Diphtheria Immunization. ROY W. PRYER, D.P.H., State Department of Health Laboratories, Lansing, Mich.
- Modified Iodine Pentoxide Method for Determination of Carbon Monoxide in Air and Blood. MATHEW J. MARTINEK, Senior Sanitary Chemist, and WILLIAM C. MARTI, Principal Chemist, Department of Health, Chicago, Ill. (*Stereopticon Illustration.*)
- Bacteriophage from a Public Health Standpoint. NEWTON W. LARKUM, PH.D., State Department of Health Laboratories, Lansing, Mich.

HEALTH OFFICERS

First Session—Tuesday a. m.

- Relation between Ultra-violet Rays and Vital Statistics. ERROL M. COADE, and I. S. FALK, PH.D., Department of Hygiene and Bacteriology, University of Chicago, Chicago, Ill., with the coöperation of HERMAN N. BUNDESEN, M.D., President, American Public Health Association, and ARTHUR J. DEMPSTER, PH.D., University of Chicago, Chicago, Ill.

Ultra-violet Therapy and Public Health Clinics. H. J. GERSTENBERGER, M.D., Babies and Children's Hospital, Cleveland, O. (*Stereopticon Illustration.*)

The Prevention of Air Pollution. ROBERT D. MACLAURIN, PH.D., Department of Public Health and Welfare, Cleveland, O. (*Stereopticon Illustration.*)

Discussion. HARRY L. ROCKWOOD, M.D., Commissioner of Health, Cleveland, O.

The Effect of Atmospheric Pollution in Baltimore upon the Incidence of Solar Ultra-violet Light. J. H. SHRADER, PH.D., President, Research Laboratories, National Dairy Products Corporation, Baltimore, Md., M. H. COBLENTZ, Chief, Division of Chemical Technology and FERDINAND A. KORFF, Chief of Laboratory, Division of Food and Chemistry, Department of Health, Baltimore, Md.

Actinic Measurement of Solar Ultra-violet Light and some Correlations with the Erythema Dose. FRED O. TONNEY, M.D., PAUL P. SOMERS, and WILLIAM C. MARTI, Bureau of Laboratories and Research, Department of Health, Chicago, Ill. (*Stereopticon Illustration.*)

Four Years' Experience with a Consolidated Inspection Service in the Chicago Department of Health. G. KOEHLER, M.D., Assistant Commissioner of Health, and JOHN M. MURPHY, M.D., Chief of Bureau of Inspection Service, Department of Health, Chicago, Ill.

Second Session—Wednesday a. m.

Health Demonstrations. GEORGE C. RUHLAND, M.D., Health Commissioner, Syracuse, N. Y.

Discussion. WALTER H. BROWN, M.D., Palo Alto, Calif., and L. D. BRISTOL, M.D., Executive Secretary, Bellevue-Yorkville Health Demonstration, New York, N. Y.

Practical Points about Active Immunization against Diphtheria and Scarlet Fever. WILLIAM H. PARK, M.D., Director of Laboratories, Department of Health, New York, N. Y., and MAY C. SCHRODER, M.D., Bureau of Laboratories, New York, N. Y.

Active Scarlet Fever Immunization. S. S. WINNER, M.D., Chicago, Ill.

Report of Work of Committee on Administrative Practice. C.-E. A. WINSLOW, DR.P.H., Professor of Public Health, Yale University, New Haven, Conn.

The Care of Communicable Diseases in General Hospitals. DENNETT L. RICHARDSON, M.D., City Hospital, Providence, R. I.

Discussion. W. S. RANKIN, M.D., Duke Endowment, Charlotte, N. C.

The Revision of the Appraisal Form. GEORGE T. PALMER, D.P.H., Director, Division of Research, American Child Health Association, New York, N. Y.

Third Session—Thursday a. m.

RURAL HEALTH PRACTICE

Modern Rural Health Practice. W. K. SHARP, JR., M.D., State Department of Health, Nashville, Tenn.

Discussion. JOHN A. FERRELL, M.D., International Health Board, New York, N. Y., and L. L. LUMSDEN, M.D., Hygienic Laboratory, U. S. Public Health Service, Washington, D. C.

Fundamental Principles of Rural Health Service. WILLIAM S. KEISTER, M.D., Deputy State and County Health Officer, Md.

Discussion. H. S. MUSTARD, M.D., Director Child Health Demonstration, Murfreesboro, Tenn., and FELIX J. UNDERWOOD, M.D., Executive Officer, State Board of Health, Jackson, Miss.

The Problem of Finance. DOUGLAS L. CANNON, M.D., Assistant State Health Officer, Montgomery, Ala.

Discussion. CHARLES O'H. LAUGHINGHOUSE, M.D., State Health Officer, Raleigh, N. C.

The Problem of Trained Personnel. C. N. LEACH, M.D., International Health Division, Rockefeller Foundation, New York, N. Y.

Discussion. JOHN E. MONGER, M.D., State Director of Health, Columbus, O., and N. E. BARNES, M.D., Health Commissioner, Greenville, O.

Measurements of Efficiency and Adequacy. JOSEPH W. MOUNTIN, M.D., U. S. Public Health Service, Nashville, Tenn. (*Stereopticon Illustration.*)

Discussion. W. F. WALKER, D.P.H., American Public Health Association, New York, N. Y., and E. R. SHAFER, M.D., State Department of Health, Columbus, O.

The Strength and the Weaknesses of County Health Organizations. M. E. BARNES, M.D., Health Commissioner, Greenville, O.

VITAL STATISTICS

First Session—Tuesday p. m.

Our National Accident Problem. CHARLES B. SCOTT, Manager, Bureau of Safety, Chicago, Ill.

Discussion. W. THURBER FALES, PH.D., Director, Bureau of Vital Statistics, State Board of Health, Montgomery, Ala.

What We Do Not Know About Accidents. R. L. FORNEY, Statistician, Public Safety Division, National Safety Council, Chicago, Ill.

Discussion. E. S. MACPHAIL, Superintendent, Census and Vital Statistics Branch, Bureau of Statistics, Ottawa, Ont.

What We Are Learning About Accidents from Vital Statistics Records. EARLE G. BROWN, M.D., Secretary State Board of Health, Topeka, Kan., and JAMES E. BAUMAN, Assistant Director, State Department of Health, Columbus, O.

Discussion. HERMAN T. PECK, M.D., General Medical Director, Field Medical Bureau, Department of Health, New York, N. Y.

Second Session—Wednesday a. m.

Section Business

Report of Nominating Committee and Election of Officers.

Report of Committee on Registration Affairs. *Chairman,* WILLIAM H. DAVIS, M.D., U. S. Bureau of the Census, Washington, D. C.

Report of Committee on Forms and Methods of Statistical Practice. *Chairman,* WILLIAM H. DAVIS, M.D., U. S. Bureau of the Census, Washington, D. C.

Report of Committee on Accuracy of Certified Causes of Death and Its Relation to Mortality Statistics and the International List. *Chairman*, HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

Report of the Committee to Aid Completion of the Registration Area Before 1930. *Chairman*, LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Report of Committee on Public Health Climatology. *Chairman*, EDWIN W. KOPF, Assistant Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Report of Committee on Vital Statistics Training. *Chairman*, W. J. V. DEACON, M.D., State Department of Health, Lansing, Mich.

Discussion on Section Betterment.

Third Session—Thursday p. m.

Report of Committee on Proper Allocation of Records. *Chairman*, J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Extent to Which Residence Influences the Recorded Death Rates from Cancer. J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Reallocation of Non-Resident Deaths. WILLIAM C. WELLING, Director, Bureau of Vital Statistics, State Department of Health, Hartford, Conn.

Relation of Climate to Tuberculosis. ROBERT BRUCE WATSON, Industrial Secretary, New Jersey Tuberculosis League, Newark, N. J.

Tuberculosis in Racial Types, with Special Reference to Mexicans. BENJAMIN GOLDBERG, M.D., Secretary, Board of Directors, Municipal Tuberculosis Sanatorium, Chicago, Ill.

Fourth Session—Friday a. m.

Geographic Distribution of Deaths from Diphtheria. DONALD B. ARMSTRONG, M.D., Sc.D., Welfare Department, and GEORGE H. VAN BUREN, Supervisor, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

Practical Use of Vital Statistics in the Establishment of Neighborhood Health Work in New York City. G. J. DROLET, Consulting Statistician, Bellevue-Yorkville Health Demonstration, New York, N. Y. (*Stereopticon Illustration.*)

Vital Statistics in Insurance. EDWIN W. KOPF, Assistant Statistician, Metropolitan Life Insurance Company, New York, N. Y.

A Comparison of Two Methods of Obtaining Epidemic Cycles. G. E. HARMON, M.D., Western Reserve University, Cleveland, O. (*Stereopticon Illustration.*)

Total Mortality Data in New York City, 1866-1927. HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

Discussion. WILLIAM H. GUILFOY, M.D., Health Department, New York, N. Y. (*Stereopticon Illustration.*)

PUBLIC HEALTH ENGINEERING

First Session—Monday p. m.

A County Wide Screening Campaign. HOWARD R. FULLERTON, Director, Division of Sanitary Engineering, Tennessee Department of Public Health, Nashville, Tenn. (*Stereopticon Illustration.*)

Carbon Monoxide Pollution of Air in Chicago. JOEL I. CONNOLLY, Chief, Bureau of Sanitary Engineering, MATHEW J. MARTINEK, Senior Sanitary Chemist, and JOHN J. AEBERLY, JR., Chief, Division of Ventilation, Department of Health, Chicago, Ill. (*Stereopticon Illustration.*)

Body Temperature Regulation and Other Physiological Reactions in Their Relation to Atmospheric Conditions. F. C. HOUGHTON, Director Research Laboratories, American Society of Heating and Ventilating Engineers, Pittsburgh, Pa.

SYMPOSIUM ON SCHOOL ROOM VENTILATION

Reports on Schoolroom Ventilation Studies:

a. *New Haven, Conn.*

LEONARD GREENBURG, PH.D., Yale University, New Haven, Conn.

b. *Cleveland, O.*

LYMAN W. CHILDS, M.D., Supervisor of Health Service, Board of Education, Cleveland, O.

c. *Chicago, Ill., Suburbs*

H. J. SHAUGHNESSY, PH.D., Department of Hygiene, University of Chicago, Chicago, Ill.

d. *Syracuse, N. Y.*

THOMAS J. DUFFIELD, Executive Secretary, New York State Commission on Ventilation, New York, N. Y.

Discussion. A. C. WILLARD, President American Society of Heating and Ventilating Engineers, Urbana, Ill., and C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

Discussion.

Second Session—Tuesday p. m.

Report of Committee on Milk Supply. *Chairman,* H. A. WHITTAKER, Director, Division of Sanitation, Minnesota Department of Health, Minneapolis, Minn.

North Carolina's Milk Control Program. H. E. MILLER, Director, Bureau of Sanitary Engineering, State Board of Health, Raleigh, N. C.

Discussion. 10 minutes.

SYMPOSIUM ON STERILIZATION OF MILK CONTAINERS AND EQUIPMENT

Milking Machines and Milk Plant Equipment. M. J. PRUCHA, Professor of Dairy Products, University of Illinois, Urbana, Ill.

Milk Utensils. WILLIAM E. REID, Associate Professor of Dairy Manufactures, University of Missouri, Columbia, Mo.

Milk Bottles. LEWIS SHERE and GERALD L. HIEFT, Department of Health, Chicago, Ill.

SYMPOSIUM ON SHELLFISH SANITATION

The Federal Shellfish Control Program. R. E. TARBETT, Sanitary Engineer, U. S. Public Health Service, Washington, D. C.

Discussion. STEPHEN DEM. GAGE, Sanitary Engineer, State Board of Health, Providence, R. I., and ABEL WOLMAN, Chief Engineer, State Board of Health, Baltimore, Md.

Public Health Engineering Standards and Shellfish Sanitation. WILLIAM F. WELLS, Biological Engineer, North Atlantic Oyster Farms, Inc., West Sayville, L. I., N. Y.

Discussion. GEORGE W. FULLER, Consulting Engineer, Fuller and McClinck, New York, N. Y., and CARL SPEER, JR., Sanitary Engineer, Chicago, Ill.

Discussion.

*Dinner Session—Tuesday**Third Session—Wednesday a. m.*

SYMPOSIUM ON FINANCING WATER SUPPLY AND SEWERAGE PROJECTS

Financing Sewerage Improvements. LANGDON PEARSE, Sanitary Engineer, Chicago Sanitary District, Chicago, Ill.

Discussion. HARRY F. FERGUSON, Chief Engineer, State Department of Health, Springfield, Ill., and J. RALPH VAN DUYN, Chief Engineer, Passaic Valley Sewerage Commission, Newark, N. J.

Financing Water Supply Improvements. WILLIAM H. DITTOE, Chief Engineer, Mahoning Valley Sanitary District, Youngstown, O.

Discussion. W. W. BRUSH, Chief Engineer, Bureau of Water, New York, N. Y., and A. K. WARREN, Chief Engineer, Sanitation District of Los Angeles County, Los Angeles, Calif.

Financing for Water Supply and Sewerage Improvements. GEORGE G. EARL, General Superintendent and Chief Engineer, Sewerage and Water Board, New Orleans, La.

Discussion. J. CLARK KEITH, Chief Engineer, Essex Border Utilities Commission, Windsor, Ont.

Watershed Sanitation. E. SHERMAN CHASE, Metcalf and Eddy, Boston, Mass.

*Luncheon Session—Wednesday**Fourth Session—Thursday a. m.*

SYMPOSIUM ON THE DISPOSAL OF PHENOL WASTES

Results Obtained in Phenol Waste Disposal under the Ohio River Basin Interstate Stream Conservation Agreement. F. HOLMAN WARING, Chief Engineer, State Department of Health, Columbus, O.

Discussion. WILLIAM L. STEVENSON, Chief Engineer, State Department of Health, Harrisburg, Pa., ELLIS S. TISDALE, Director, Division of Sanitary Engineering, State Department of Health, Charleston, W. Va., and C. A. HOLMQUIST, Director, Division of Sanitation, State Department of Health, Albany, N. Y.

Industry's Problem in the Disposal of Phenol Wastes. F. F. MARQUARD, Assistant General Manager, Carnegie Steel Company, Clairton, Pa., F. W. SPERR, JR., Director of Research, Koppers Company, Mellon

- Institute, Pittsburgh, Pa., and C. L. WAGGONER, Superintendent, Coke Oven Plant, By-Products Coke Corporation, Chicago, Ill.
- Biochemical Oxidation of Phenolic Wastes. FLOYD W. MOHLMAN, PH.D., Chief Chemist, Chicago Sanitary District, Chicago, Ill.
- Discussion.* WILLIAM A. RYAN, Chemist, Department of Public Works, Rochester, N. Y.

INDUSTRIAL HYGIENE

First Session—Tuesday p. m.

- Industrial Fatigue (Including Report of Committee for the Study of Industrial Fatigue). *Chairman*, EUGENE LYMAN FISK, M.D., Medical Director, Life Extension Institute, New York, N. Y.
- Mortality Trends in the Industrial Population. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.
- The Outlook for Occupational Mortality Statistics. LEON E. TRUESDELL, Chief Statistician for Population, U. S. Bureau of the Census, Washington, D. C.
- Discussion.* DEAN K. BRUNDAGE, U. S. Public Health Service, Washington, D. C., and EUGENE LYMAN FISK, M.D., Medical Director, Life Extension Institute, New York, N. Y.
- Report of Committee on Status of Silicosis. R. R. SAYERS, M.D., Chief Surgeon, U. S. Bureau of Mines, Washington, D. C.

Luncheon Session—Wednesday

- Report of Committee on Occupational Morbidity Statistics. WADE WRIGHT, M.D., Assistant Medical Director, Policy Holders Service Bureau, Metropolitan Life Insurance Company, New York, N. Y.
- Round Table Discussion*, Industrial Fatigue. (Also impressions of Fifth International Medical Congress on Industrial Accidents and Occupational Diseases, Budapest, September 2-8, and The Royal Institute of Public Health, Dublin, August 15-20, by EMERY R. HAYHURST, M.D., and others.)
- The Possible Relationship of Mutual Benefit Associations to the Health of Employees.

Second Session—Thursday p. m.

- Mobilizing Mutual Benefit Associations to Include Health Activities. MAGNUS W. ALEXANDER, President, National Industrial Conference Board, New York, N. Y.
- Discussion.* MEYER BLOOMFIELD, Consultant on Industrial Relations, New York, N. Y., WILLIAM A. SAWYER, M.D., Medical Director, Eastman Kodak Company, Rochester, N. Y., E. B. HUNT, Superintendent, Pennsylvania Railroad Voluntary Relief Department, Philadelphia, Pa., and VOLNEY S. CHENEY, M.D., Medical Director, Armour and Company, Chicago, Ill.
- Report of the Committee on the Status of Lead Poisoning in the United States for the Year Ending June 30, 1928. CAREY P. MCCORD, M.D., and DOROTHY K. MINSTER, Industrial Health Conserv-

ancy Laboratories, and ROBERT KEHOE, M.D., University of Cincinnati, Cincinnati, O.

Report of Committee on Standard Practices in the Compensation of Occupational Diseases. A. J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

Report of Committee on Volatile Solvents. ALICE HAMILTON, M.D., Harvard School of Public Health, Boston, Mass.

Report of Committee on Skin Irritants. HENRY FIELD SMYTH, M.D., Dr.P.H., Laboratory of Hygiene, University of Pennsylvania, Philadelphia, Pa.

Third Session—Friday a. m.

How Employe Magazines Can be Used to Promote Health. MEYER BLOOMFIELD, Consultant on Industrial Relations, New York, N. Y.

Extension of Industrial Hygiene by Tuberculosis Associations in the United States. BERNARD S. COLEMAN, Executive Secretary, Hudson County Tuberculosis League, Jersey City, N. J.

The Tuberculous Worker and His Placement in Industry. C. W. BERGQUIST, President, Chicago Tuberculosis Institute, Chicago, Ill.

Discussion. WADE WRIGHT, M.D., Assistant Medical Director, Policy Holders Service Bureau, Metropolitan Life Insurance Company, New York, N. Y., and EMERY R. HAYHURST, M.D., College of Medicine, Ohio State University, Columbus, O.

Health Education in an Industrial Plant. JOHN B. GIBSON, Director of Safety and Health, Western Electric Company, Chicago, Ill.

Public Health and Medical Work in a Large Coal Company. DANIEL J. KINDEL, M.D., Medical Director, The Consolidation Coal Company, Fairmont, W. Va. (*Stereopticon Illustration.*)

Discussion. LLOYD NOLAND, M.D., Chief Surgeon, Tennessee Coal, Iron and Railroad Company, Birmingham, Ala.

FOOD, DRUGS AND NUTRITION

First Session—Wednesday a. m.

Report of the Committee on Beverages. T. J. KING, Supervising Food Inspector, Department of Health, Chicago, Ill.

Report of the Committee on Fruits, Vegetables and their Products. *Chairman*, H. M. LOOMIS, U. S. Public Health Service, Washington, D. C.

Report of the Committee on Cereals and their Products. *Chairman*, F. C. BLANCK, Ph.D., Bureau of Chemistry and Soils, Washington, D. C.

Report of the Committee on Meat, Fish and Shellfish. *Chairman*, CARL R. FELLERS, Ph.D., Massachusetts Agricultural College, Amherst, Mass.

Report of the Committee on Nutritional Problems. *Chairman*, PROFESSOR HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

What We Should Strive for in Food Advertising. PROFESSOR E. V. MCCOLLUM, Johns Hopkins School of Hygiene and Public Health, Baltimore, Md.

Second Session—Thursday p. m.

- Health Significance of Small Amounts of Metals. J. S. MCHARGUE.
Some Aspects of Intestinal Bacteriology in Relation to Health.
PROFESSOR LEO F. RETTGER, New Haven, Conn.
- Evaporated Milk and Its Relation to Public Health. FRANK E. RICE,
Executive Secretary, Evaporated Milk Association, Chicago, Ill.
- Ice Cream Control. FREDERICK W. FABIAN, Associate Professor of Bacteriology and Hygiene, Michigan State College, East Lansing, Mich.
- The Use of Ultra-violet Transmitting Glass. WALTER H. EDDY,
PH.D., Professor of Physiological Chemistry, Teachers College, Columbia University, New York, N. Y. (*Stereopticon Illustration.*)
- Certificates of Approval for Food Establishments Complying with Ordinances. JAMES P. KILCOURSE, LL.B., Chief, Bureau of Food Inspection, Department of Health, Chicago, Ill.

CHILD HYGIENE

(These Sessions are Joint with the American Child Health Association.)

First Session—Wednesday a. m.

SCHOOL MEDICAL AND NURSING SERVICE

- Sickness and Absence Records in the School Health Program.
Methods and Procedures and the Values Resulting. O. B. NESBIT,
M.D., Director of Medical Inspection, Public Schools, Gary, Ind.
- The Place of Sickness Records in the School Health Program.
SELWYN D. COLLINS, PH.D., Associate Statistician, U. S. Public Health Service, Washington, D. C. (*Stereopticon Illustration.*)
- Discussion.* HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.
- Business of Child Hygiene Section*
- Physical Determinants of Individual Differences in Weight.
RAYMOND FRANZEN, PH.D., Research Director, School Health Study, American Child Health Association, New York, N. Y.
- Discussion*
- Four-Year Child Health Study of an American Community, A Report of Progress of an Investigation on Grosse Ile, Mich.
CHARLES A. WILSON, M.D., Merrill-Palmer School, Detroit, Mich. (*Stereopticon Illustration.*)
- Discussion.* Opened by E. V. MCCOLLUM, PH.D., Professor of Chemical Hygiene, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Second Session—Wednesday p. m.

- How Can We Improve Our Procedures for Correction of Physical Defects? WALTER S. CORNELL, M.D., Director, Medical Inspection of Public Schools, Philadelphia, Pa.
- The Nurse's Activities to Obtain the Correction of Physical Defects.
ANN DICKIE BOYD, R.N., Supervisor of Nurses, Public Schools, Denver, Colo.

Discussion. FRED MOORE, M.D., Director Health Department of Public Schools, Board of Education, Des Moines, Ia.

What is the Teacher's Part in the Program to Get Physical Defects Corrected? GEORGIE B. COLLINS, Assistant Editor of Health Films, Eastman Teaching Films, Inc., formerly Director of Health Education, Public Schools, Malden, Mass.

Discussion

School Medical Service in a Continuation School. E. H. LEWINSKI-CORWIN, PH.D., Executive Secretary, Public Health Relations Committee, Academy of Medicine, New York, N. Y.

Discussion. EMMA MCKAY APPEL, M.D., Medical Examiner, Vocational Guidance Bureau, Board of Education, Chicago, Ill.

A Practical Method of Recording Physical Defects and Their Correction. LEON BANOV, M.D., Health Officer, Charleston, S. C.

Third Session—Thursday a. m.

DENTAL HYGIENE

What Habit, Attitude and Knowledge Objectives Should be Sought at Various Age Levels? Discussion Based on Mouth Hygiene Materials in *Health Behavior*, by Wood and Lerrigo, published by The Public School Publishing Company, Bloomington, Ill. HARRY S. THOMSON, S.D., M.D., Field Secretary, Canadian Dental Hygiene Council, Toronto, Ont.

Discussion.

Discussion on Dental Health Education Materials Designed for School Use Collected with the Coöperation of the American Dental Association. Criticisms and Suggestions from Point of View of Subject Matter. WILLIAM R. DAVIS, D.D.S., Director, Bureau of Mouth Hygiene, State Department of Health, Lansing, Mich.

Discussion

Dental Health Education Materials from Point of View of Educational Presentation and Usefulness. MARION O. LERRIGO, PH.D., New York, N. Y.

Discussion.

Summary and Comments. GUY S. MILLBURY, D.D.S., Dean, College of Dentistry, University of California, San Francisco, Calif.

PUBLIC HEALTH EDUCATION

Luncheon Session—Monday

High Spots in 1927-1928—New Ideas and successful methods.

Luncheon Session—Tuesday

Program for Health Education Training in Teachers' Colleges. MARY L. HAHN, State Department of Health, Springfield, Ill.

Dinner Session—Tuesday

Business Conference of Public Health Education Section (Closed Session)

Luncheon Session—Wednesday

Why Some of the Exhibits Are Good—Constructive discussion of the scientific exhibits

First Session—Wednesday p. m.

STEPS IN PLANNING A HEALTH EDUCATION AND PUBLICITY

PROGRAM—PART I

An Introduction to Planning. MARY SWAIN ROUTZAHN, Russell Sage Foundation, New York, N. Y.

Objectives of Publicity—On what basis are they selected?

HOWARD W. GREEN, Secretary, Cleveland Health Council, Cleveland, O.

Audiences—How to select and classify them? MARJORIE DELEVAN, Bureau of Education, Michigan Department of Health, Lansing, Mich.

The Facts—How decide what is to be told? C.-E. A. WINSLOW, DR.P.H., Professor of Public Health, Yale University, New Haven, Conn.

Second Session—Thursday a. m.

STEPS IN PLANNING A HEALTH EDUCATION AND PUBLICITY

PROGRAM—PART II

The Approach—How decide on the motives for conduct to which an appeal will be made? FRANKLIN FEARING, Professor of Psychology, Northwestern University, Evanston, Ill.

The Methods—On what basis should they be selected? KATHRYNE M. RADEBAUGH, Executive Secretary, Hennepin County Tuberculosis Association, Minneapolis, Minn.

Examples of Health Education and Publicity Programs—A review of current practice. IAGO GALDSTON, M.D., Bureau of Health Education, New York Tuberculosis and Health Association, New York, N. Y. (Mimeographed copies of sample programs available in advance at Information Desk and Education and Publicity Headquarters)

Luncheon Session—Thursday

Diphtheria Campaigning—What is new? What is difficult? MARIE F. KIRWAN, Tuberculosis and Public Health Committee, State Charities Aid Association, New York, N. Y.

PUBLIC HEALTH NURSING

First Session—Monday p. m.

Staff Education—Means By Which a City Combined Official and Voluntary Nursing Services. VIRGINIA GIBBES MCPHEETERS, R.N., Director of Public Health Nursing, Coöperative Nursing Association, Charlotte, N. C.

Discussion.

The Health Officer's Responsibility for Staff Education.

The Educational Directors Responsibility. JOSEPHINE F. GOLDSMITH, R.N., Director of Nurse Education, Department of Health, Syracuse, N. Y.

Common Interest Problems of State Directors of Public Health Nursing. EVA F. MACDOUGALL, R.N., State Board of Health, Indianapolis, Ind.

Discussion. ZOE MCCALED, R.N., Director of Public Health Nursing, State Board of Health, Columbus, O., and PEARL MCIVER, R.N., Director of Public Health Nursing, State Board of Health, Jefferson City, Mo.

Luncheon Session—Wednesday

Second Session—Thursday p. m.

Section Business.

Public Health Nursing Report of Editorial Committee. MIRIAM AMES, R.N., John Hancock Life Insurance Company, Boston, Mass.

Report of Advisory Committee on Public Health Nursing. SOPHIE C. NELSON, R.N., John Hancock Life Insurance Company, Boston, Mass.

TRIPS OF GENERAL INTEREST, SPECIFIC INFORMATION AND PLEASURE

Chicago offers visitors unusual opportunities to investigate practical public health programs, and elaborate plans have been made by the Chicago Local Committee for the entertainment of delegates and guests at the 57th Annual Meeting of the Association in Chicago next month.

In arranging these trips the Local Committee has scheduled some that will be of general interest to those attending the meeting and it has planned a series of trips of specific interest to the several groups of the American Public Health Association, the American Child Health Association and other organizations to be represented.

Among the 81 trips planned, 18 are scheduled trips, 7 of general interest,

and 11 for the special groups, including laboratory technicians, nutritionists, public health nurses, child hygienists, welfare workers, social hygienists, industrial hygienists, public health engineers, food and drugs specialists, rural sanitarians, and vital statisticians.

All scheduled trips will be arranged at a time convenient for those most interested.

Listed among the scheduled trips are visits to hospitals and public institutions including Cook County Hospital, the Illinois Research Hospital, Municipal Contagious Disease Hospital, Daily News Sanitarium for Children and Mothers, Children's Memorial Hospital, Municipal Tuberculosis Sanitarium, the Medical Schools of Chicago University and Northwestern University; to dairy product plants including the Wanzer

Sunlight Milk, People's Ice Cream Company, the Bowman Dairy Company, the Borden Dairy Company and Christiansen Brothers; research laboratories of the Fire Underwriters, University of Chicago, and the City of Chicago Experimental Water Filtration Laboratory; Hull House Settlement, Columbus Park Infant Welfare Station, nursery schools, the Spaulding School for Convalescent Care of Poliomyelitis, prenatal and pre-school clinics, Visiting Nurses Association, Sears Roebuck Company, Institute for Juvenile Research, Juvenile Court and Juvenile Detention Home of Cook County, venereal disease clinic of the Chicago Department of Health, International Harvester Company, Pullman Company, ventilation plant of Chicago Theater, Illinois Steel Company, Union Stock Yards, Chicago Experimental Water Filtration Plant, 68th Street. Pumping Station and Chlorination Plant, Calumet Sewage Treatment Plant of Chicago Sanitary District, Chicago Produce Market, Chicago Cold Storage Warehouse, Cook County Dental Clinic, Des-Plaines School of Health, Camp Remberg, and the statistical departments of the City of Chicago, Department of Health, Illinois Bell Telephone Company.

In addition to these scheduled trips the Local Committee has listed 63 places of general and special interest. Information regarding these trips will be printed in the final program and in the *Daily Bulletin* to be issued throughout the week of the meeting.

NOTE: A description of Hull House as a Health Center, The Visiting Nurse Association of Chicago and The Infant Welfare Society of Chicago will be described in the September issue of the *Child Health Bulletin*, published by the American Child Health Association.

VARIETY OF ENTERTAINMENT FOR WOMEN GUESTS

Women delegates and guests to the meeting will be guests of the Local Com-

mittee on trips to the Field Museum of Natural History and the Chicago Art Institute to be conducted by a special guide and lecturer, and on sight-seeing trips around Chicago stopping at places of interest enroute. The Chicago Park system affords several hours' delightful drive and this will be featured in the women's entertainment program.

They will be entertained at a tea at the Ida Noyes Hall, University of Chicago, which is considered one of the most beautiful and artistic buildings for college women's activities in the country. Another tea has been arranged by the Chicago Nurses' Association, and luncheons in the Marine Dining Room of the Edgewater Beach Hotel, at the Illinois Women's Athletic Club, the Medical Arts Club, in the Red Lacquer Room of the Palmer House, and still another in the Wedgewood Room of the store of Marshall Field and Company.

The women will have an opportunity to visit Chicago's leading department stores and specialty shops and attend a Fashion Show and linen demonstration arranged especially for them through the courtesy of Marshall Field and Company. There will be a bridge party one afternoon during the week at Hotel Stevens and also several theater parties.

AMERICAN ASSOCIATION OF SCHOOL PHYSICIANS TO MEET

The American Association of School Physicians will hold its meetings at Hotel Stevens, Chicago, Ill., October 15 at 9:30 a. m., 2:00 and 6:00 p. m. The morning and afternoon sessions will be held in private Dining Room No. 1, and the evening session which is to be a dinner meeting will be held in West Ball Room and Assembly. An invitation is extended to all school physicians to attend the meetings and participate in the program.

HOTELS

A number of the Chicago hotels are listed, with their rates. This is for the convenience of delegates who desire to plan ahead. The map on page 1162 shows the location of these hotels together with many of the places of interest to vistiors. Headquarters for the Annual Meeting will be the Hotel Stevens, shown as number 1 on the map.

Applications for hotel reservations should be made directly to the hotels. A blank is supplied here for your convenience.

SUGGESTED AMENDMENT TO THE CONSTITUTION

At the recommendation of the Committee on Constitution, the following amendment will be offered for adoption at the Chicago meeting:

ARTICLE III, Section A, Part 2, at the end of the second paragraph after the word "elected" add the words "by the Governing Council."

HOTEL	HOTEL RATES			
	SINGLE		DOUBLE	
	With Bath	Without Bath	With Bath	Without Bath
Auditorium	\$3.40- 6.00	\$2.00-3.00	\$5.00- 8.00	\$3.00-5.00
Blackstone	5.00-14.00	4.00-5.00	6.00-16.00	5.00
Congress	4.00-10.00	3.00-5.00	6.00-12.00	4.00-6.00
Drake	5.00-10.00		6.00-14.00

REDUCED RAILROAD RATES

Persons attending the 57th Annual Meeting of the Association and related meetings in Chicago, October 15-19, will be granted a rate of one and one-half times a single fare by the railroads from the starting point to Chicago and return.

To obtain the reduced rate it is necessary to obtain from the ticket agent a reduced fare certificate when purchasing your ticket for Chicago. This reduction is available to all delegates and members of their families attending the Annual Meeting of the American Public Health Association, the American Child Health Association, the American Social Hygiene Association, the International Association of Dairy and Milk Inspectors and other meetings being held at the same time and place.

Ask for a certificate for the meeting of the A.P.H.A. and related societies. This certificate when validated by the Executive Secretary of the A.P.H.A. at the Chicago meeting will entitle the purchaser to a return ticket at half fare.

Detailed information regarding railroad rates and transportation will be sent to members of the Association in a letter from the Executive Secretary the first week in September.

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-Laws as amended in October, 1926, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, provided such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Chicago, will be elected for the 3-year term, 1928-1931.

Richard A. Bolt, M.D.,
Assistant Professor of Child Hygiene,
University of California,
Berkeley, Calif.

Hugh S. Cumming,
Surgeon General,
U. S. Public Health Service,
Washington, D. C.

Michael M. Davis, Ph.D.,
New York, N. Y.

W. J. V. Deacon, M.D.,
State Health Department,
Lansing, Mich.

J. G. Fitzgerald,
Connaught Laboratories,
University of Toronto,
Toronto, Ont.

Elizabeth G. Fox, R.N.,
American Red Cross,
Washington, D. C.

Leslie C. Frank, C.E.,
U. S. Public Health Service,
Montgomery, Ala.

Lee K. Frankel, Ph.D.,
2nd Vice-President,
Metropolitan Life Insurance Company,
New York, N. Y.

Norman MacL. Harris, M.B.,
Chief, Laboratory of Hygiene,
Department of Health,
Ottawa, Ont.

George D. Lummis, M.D.,
Middletown, O.

Professor, E. V. McCollum,
Johns Hopkins School of Hygiene and
Public Health,
Baltimore, Md.

A. T. McCormack, M.D.,
State Health Officer,
Louisville, Ky.

J. W. S. McCullough, M.D.,
Provincial Board of Health,
Toronto, Ont.

Sophie C. Nelson, R.N.,
Visiting Nurse Service,
John Hancock Mutual Life Insurance Co.,
Boston, Mass.

Stanley H. Osborn, M.D.,
State Health Commissioner,
Hartford, Conn.

George T. Palmer, D.P.H.,
American Child Health Association,
New York, N. Y.

Langdon Pearse,
Winnetka, Ill.

Roger G. Perkins, M.D.,
Cleveland, O.

J. L. Pomeroy, M.D.,
County Health Department,
Los Angeles, Calif.

Watson S. Rankin, M.D.,
Duke Endowment,
Charlotte, N. C.

Mazýck P. Ravenel, M.D.,
University of Missouri,
Columbia, Mo.

Evart G. Routzahn,
Russell Sage Foundation,
New York, N. Y.

William P. Shepard, M.D.,
Assistant Secretary, Welfare Division,
Metropolitan Life Insurance Company,
San Francisco, Calif.

William F. Snow, M.D.,
General Director, } of
American Social Hygiene Association }
New York, N. Y.

James A. Tobey, Dr.P.H.,
Borden Sales Company,
New York, N. Y.

S. W. Welch, M.D.,
State Health Commissioner,
Montgomery, Ala.

H. A. Whittaker,
State Board of Health,
Minneapolis, Minn.

C. F. Wilinsky, M.D.,
Health Department,
Boston, Mass.

Linsly R. Williams, M.D.,
Director, New York Academy of Medicine,
New York, N. Y.

NOMINATING COMMITTEE

Edwin O. Jordan, *Chairman*
Walter H. Brown John Sundwall
A. J. Chesley C.-E. A. Winslow

NEW MEMBERS

- Victoriano Agostini, M.D., Havana, Cuba, Chief of School Hygiene
- Ada H. Arlitt, Ph.D., Cincinnati, O., Professor of Child Care and Training, University of Cincinnati
- A. L. de Barros Barreto, M.D., Dr.P.H., Sao Salvador, Bahia, Brazil, Director State Board of Health (Assoc.)
- Miriam Birdseye, A.M., Washington, D. C., Extension Nutritionist, U. S. Department of Agriculture
- Hazel E. Branch, Ph.D., Wichita, Kan., Teacher in Preventive Medicine
- Harvey J. Burkhart, D.D.S., Rochester, N. Y., Director Rochester Dental Dispensary
- Francis L. Burnett, M.D., Boston, Mass., Research in Nutrition
- Mrs. William H. Carpenter, R.N., Salem, Va., Community Nurse
- Thomas J. Claffy, Chicago, Ill., Chief of Plumbing Division, Department of Health
- Lydia Clark, Columbus, O., Professor of Physical Education, Ohio State University
- Timothy R. Crowe, Chicago, Ill., President Sanitary District of Chicago
- Matthew A. DeLaney, Manila, P. I., Medical Officer, U. S. Army
- Chester F. Drake, D.Sc., Aspinwall, Pa., Superintendent Pittsburgh Filtration Plant
- Herbert C. Ellis, B.S., Detroit, Mich., Associate Structural Engineer, Detroit Water Board
- Robert B. Faus, M.D., Honolulu, T.H., Director Emergency Hospital
- Morris Fishbein, M.D., Chicago, Ill., Editor *Journal of American Medical Association and Hygeia*
- Helen W. Ford, Manhattan, Kans., Head, Department of Child Welfare and Euthenics, Kansas State Agricultural College
- Julio Freijanes, M.D., C.P.H., Guadalajara, Spain, Inspector Provincial se Sanidad, Gobierno Civil (Assoc.)
- Marie E. Fuller, R.N., Providence, R. I., Industrial Nurse
- Melvin S. Gaul, Chicago, Ill., (Assoc.)
- George A. Hastings, New York, N. Y., Assistant Secretary, State Charities Aid Association
- Scott W. Hollis, M.D., Abilene, Tex., City and County Health Officer
- Emily M. Hopkins, R.N., Logan, O., Public Health Nurse, Board of Health
- Omar C. Hopkins, S.M., Atlanta, Ga., Junior Assistant Sanitary Engineer, U. S. Public Health Service
- Wayne E. Ishyam, Los Angeles, Calif., Junior Sanitary and Food Officer
- Harvey P. Jones, B.C.E., Toledo, O., Consulting Sanitary Engineer
- Frank J. Keis, Fort Lauderdale, Fla., Consulting Engineer
- William H. Kelly, M.D., Sanford, Me., City Health Officer
- Eva Kingelin, R.N., Milwaukee, Wis., Industrial Nurse, Kochring Company
- George F. Lee, Johnstown, Pa., Chemist and Bacteriologist
- Harry G. Lindquist, M.S., Amherst, Mass., Instructor in Dairying, Massachusetts Agricultural College
- Eva F. MacDougall, R.N., A.B., Indianapolis, Ind., Director Division of Public Health Nursing, State Board of Health
- Merrill J. Mack, M.Sc., Amherst, Mass., Assistant Professor of Dairying, Massachusetts Agricultural College
- J. G. McMaster, M.D., Florence, S. C., City Health Officer
- Major John I. McWilliams, Pine Camp, Great Bend, N. Y., Construction and Sanitary Engineer
- Fred L. Moore, M.D., Blountville, Tenn., Director, Sullivan County Health Unit
- Robert P. Myers, Ph.D., M.S., Evansville, Ind., Bacteriologist, Research Laboratory, Mead, Johnson & Company
- Henry C. Niblack, M.D., Chicago, Ill., Chief Bureau of Child Welfare, Department of Health
- Charles M. Pearce, M.D., McAlester, Okla., Superintendent of Health, Pittsburg County
- Anne F. Pritchett, Hannibal, Mo., Red Cross Public Health Nurse
- Enrico Rangel, M.D., Rio de Janeiro, Brazil, Assistant in Vital Statistics, Department of Public Health (Assoc.)
- Margaretta W. Reeve, Philadelphia, Pa., Campaign Director, National Congress of Parents and Teachers
- Esther L. Richards, M.D., D.Sc., Baltimore, Md., Associate Professor of Psychiatry, Johns Hopkins Hospital, and Lecturer in Mental Hygiene, Johns Hopkins University
- Jane D. Rippin, New York, N. Y., Director of Section on Women and Girls of the War and Navy Department, Commission on Training Camp Activities, Girl Scout Health Program
- Clyde R. Salmons, D.D.S., Hartford, Conn., Chief Mouth Hygiene Department, Child Hygiene Bureau, State Department of Health

Harriet J. Sherman, R.N., Jacksonville, Fla.,
Field Supervisor Bureau of Child Hygiene
and Public Health Nursing, State Board of
Health

Irene M. Silesky, Minneapolis, Minn., Student
of Public Health, University of Minnesota

Mildred G. Smith, New York, N. Y., Staff
Associate, National Society for the Preven-
tion of Blindness

Mahidol Songkla, M.D., C.P.H., Bangkok,
Siam, Resident Physician and Pediatrician,
Siriraj Hospital, Chulalongkorn University
(Assoc.)

Alice M. Spangler, R.N., Lebanon, Pa., Nurse
Ellen E. Stevens, San Luis Obispo, Cal., Public
Health Nurse, San Luis Obispo County
Health Department

Henry Storgaard, M.D., Yakima, Wash.,
County and City Health Officer

James P. Stowe, Charlotte, N. C., Member
State Board of Health

Ira C. Tyndall, M.D., Berlin, Md., Health
Officer, Worcester County

William I. Van Arnum, Ph.G., Youngstown,
O., Chemist and Bacteriologist and Superin-
tendent of Filtration Plant

Rodrigo Varo, M.D., C.P.H., Lerida, Spain,
Provincial Health Officer, Gobierno Civil
(Assoc.)

Homer C. Vernon, Los Angeles, Calif., Junior
Sanitary Inspector

George I. Wallace, Ph.D., Urbana, Ill., Teacher
of Epidemiology, University of Illinois

F. Edward Whitehead, Ph.G., Trenton, N. J.,
Sanitary Chemist, Bureau of Engineering,
State Department of Health

Charlotte Whittton, M.A., Ottawa, Canada,
Executive Secretary Canadian Council on
Child Welfare

Marion C. Woodbury, R.N., Great Barrington,
Mass., Director Visiting Nurse Association

DECEASED MEMBERS

J. Ross Snyder, M.D., Birmingham, Ala. Mem-
ber elected 1919

John D. McCarthy, M.D., New York, N. Y.
Member elected 1928

APPLICATION FOR FELLOWSHIP

FOOD, DRUGS AND NUTRITION: Timothy J.
King, M.D., Chicago, Ill.

LABORATORY: Frank E. Greer, Chicago, Ill.
CHILD HYGIENE: Estella F. Warner, M.D.,
Salem, Ore.

UNAFFILIATED: Louis E. Schmidt, M.D.,
Chicago, Ill.

GEORGE W. PUTNAM ENGAGED AS RESEARCH ENGINEER

GEORGE W. Putnam, Fellow, A. P.
H. A., has been granted a year's
leave of absence from the position of
Chief, Bureau of Dairy Products, Chi-
cago Health Department, and is now
engaged as Research Engineer with The
Creamery Package Manufacturing Com-
pany with headquarters in Chicago.

DR. S. W. WELCH DIES

S. W. Welch, M.D., State Health Offi-
cer of Alabama since 1917, and past
president of the State and Provincial
Health Authorities of North America,
died of heart disease in Montgomery,
Ala., on August 22. He was the author
of several bills amending the medical
laws of Alabama. Dr. Welch has been a
member of the A. P. H. A. since 1917
and a Fellow since 1922.

DR. LOUIS I. HARRIS RESIGNS

LOUIS I. Harris, M.D., has resigned
as health commissioner of New York
City to become consultant to the Nation-
al Dairy Products Corporation in estab-
lishing a medical and sanitary service.

Dr. Harris was appointed health com-
missioner January 1, 1926, by Mayor
James Walker. Before resigning Dr.
Harris had completed 20 years' service
with the New York City Health Depart-
ment, and he will receive a pension of
\$5,000.

Dr. Harris is a Fellow of the A.P.H.A.
and a member of the Committee on Ven-
tilation, and of the Council of the Health
Officers Section.

On August 18, Shirley W. Wynne was
appointed by Mayor Walker to succeed
Dr. Harris.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Mortality and Morbidity in Relation to Latitude—In the densely populated sections of the country will be found a greater concentration of measles, diphtheria and scarlet fever in the early years of life. This has previously been demonstrated not only with respect to these diseases, but also to whooping cough and anterior poliomyelitis.

This tendency for measles and probably whooping cough seems to be independent of latitude or climate, but in diphtheria and scarlet fever, and apparently in poliomyelitis, the age distribution of deaths is found to be affected by another tendency, namely, a higher concentration in early childhood in tropical and sub-tropical climates. The explanation is offered that the greater concentration of diphtheria and scarlet fever in the early ages in tropical climates may be due to early and widespread immunity of the populations concerned. Sub-clinical infection would, therefore, be greater in the warm climates. This viewpoint is supported by other facts including the results of the Schick and Dick tests in tropical areas. The same explanation may hold for poliomyelitis.—James A. Doull, *Variations in the Age Distributions of Mortality and Morbidity from Diphtheria, Scarlet Fever and Certain Other Diseases in Relation to Latitude*, *Am. J. Hyg.*, VIII: 633 (July), 1928.

Diphtheria Prevention in Nurses—An accurate account has been kept of the incidence of diphtheria and scarlet fever among student nurses at the Durand Hospital of the John McCormick Institute for Infectious Diseases in Chicago since 1913. During the first few months after the opening of the hospi-

tal in March, 1913, no Schick test was employed on student nurses, and 18.4 per cent contracted diphtheria.

From October, 1914, to January, 1921, the Schick test was employed and antitoxin was given to most of the susceptibles. In the susceptible group who received antitoxin only 7.2 per cent contracted diphtheria as compared with 25 per cent who contracted diphtheria in the group of susceptibles not given antitoxin.

Beginning with January, 1921, toxin-antitoxin has been given to susceptibles. Among the susceptibles immunized to a negative test before entering the service of the institution only 0.6 per cent have contracted diphtheria. This represents but a single case in a total of 159 nurses.

The percentage of student nurses contracting scarlet fever and sore throat has decreased from 17 to 12.4 since the employment of the Dick test and immunization of susceptibles.—L. Hektoen and C. Johnson, *Prevention of Diphtheria and Scarlet Fever in Nurses*, *J. Prev. Med.*, II: 289 (July), 1928.

Epidemiology of Diphtheria—It has been recognized that the establishment of an infectious disease depends first upon the presence of the specific parasitic cause, and secondly, the susceptibility of the host. The degree of susceptibility determines whether the individual shall succumb to the disease or apparently remain healthy. Frost discusses a third result intermediate between these two—that is, the establishment of infection without manifest symptoms of the disease. He endeavors to establish a ratio for diphtheria between infections which result in the disease itself, and infections which result in

the establishment of specific immunity without the disease.

His figures are for the most part from a selected area in the City of Baltimore. The ratio may vary in relation to age, to race, to the circumstances of known exposure, and to the factors which have not been subject to analysis. The ratios obtained in Baltimore are obviously different from those obtained in other communities. Nevertheless, for the conditions of the study it may be stated that the demonstrable specific immunizations are to the recognizable case as 6 or 8 is to 1.

In response to the question of how does the frequency of bacteriologically demonstrable infection with (virulent) diphtheria bacilli compare respectively with the frequency (a) of clinical diphtheria, and (b) of specific immunization as indicated by the Schick test, the author concludes that in a representative urban population, in the broad age groups considered, bacteriologically demonstrable carrier infections are to clinical diphtheria roughly as 40 or 50 is to 1. —W. H. Frost, *Infection, Immunity and Disease in the Epidemiology of Diphtheria*, *J. Prev. Med.*, II, 325, July, 1928.

Visible Record Display Cabinet— In order to enable the health administrator to keep in a compact and attractive manner statistical information concerning the functioning of his department, which he may desire to use for demonstration purposes, the Ohio State Health Department is encouraging the use of a Visible Record Display Cabinet.

The visible display cabinet showing cumulative records of a health department for a period of years on the basis of the A.P.H.A. *Appraisal Form* is the logical outgrowth of the monthly check sheet* devised by Dr. Harry H. Mustard, Director, Child Health Demonstration, Murfreesboro, Tenn.

The scheme for keeping yearly records available as a means for easily transporting them has been developed by Dr. Porter Crawford, District Health Commissioner, Troy, O., and Dr. E. R. Shaffer, Chief, Bureau of Local Health Organization, Ohio State Department of Health.

For the cabinet which is shown in the accompanying cut the Ohio State Health Department is having printed a

standard form of report card similar to the sample shown, consisting of 6 printed cards and 4 blank cards. The printed cards are for the purpose of tabulating the data relative to the various activities, and the blank cards are provided for the purpose of constructing graphs from local data at the pleasure of the local health commissioner. The State Health Department is endeavoring to have one of these cabinets installed in the office of each full-time health organization.

One of the interesting features pertaining to the prescribed form is that it is almost an exact duplicate of the department's annual report form which is based upon the survey portion of the *Appraisal Form* for city and rural health districts, recommended by the Committee on Administrative Practice of the American Public Health Association.

Inasmuch as this Visible Record Display Cabinet is portable, it is very convenient to transport within various points of a local health district, from which the health commissioner or other speaker may give a constructive lecture, and at the same time demonstrate the statistics and other data that would be available.

* See A Suggested Monthly Check Sheet, *A. J. P. H.*, 18:3, 302 (Mar.), 1925.

**DISPLAY CASE FOR HEALTH RECORDS**

Outside dimensions, 15" wide, 21" high, and 4" deep
Contains 5 frames, dovetailed to hold card $14\frac{1}{4}$ " wide
 $\times 18\frac{3}{4}$ " high, inserted through slot in top of frame
Frames hinged together with pivot for Central support
Removable from outside case

Case provided with hinged door, clasps or fasteners, two
slotted supports for fastening to wall, and carrying
handle

Constructed of red gum, mahogany finish, inside and
out

The frames of the cabinet will accom-
modate cards $14\frac{1}{4}$ " wide by $18\frac{3}{4}$ " high.
The cabinets are manufactured at the
furniture department of the Ohio State
Reformatory, constructed from red gum
wood, finished in mahogany and may be
purchased through the Ohio State Health
Department.

LABORATORY

C. C. YOUNG

FERMENTATION TUBE

GEORGE G. SCHAUT

Chief Chemist, Bureau of Water, Philadelphia, Pa.

THE one piece type fermentation tube has always been more popular than the two-piece tube and is used with or without a pedestal base. When used without an integral base, the tube must be supported by some external means as a rack or clamp, whereas the type with the pedestal base is very fragile and the breakage excessive.

It has long been the desire of laboratories using the pedestal type to find

some way of stopping the breakage, for the writer has found in a laboratory purchasing 2400 a year the breakage in shipment alone was 10 to 15 per cent, a 10 per cent breakage upon first handling, and also a 10 per cent upon first sterilization. With this constantly in mind, the writer designed a tube (patent applied for), the type of which is shown in Figure I.

This is an integral piece of apparatus

FIGURE I
FERMENTATION TUBE
GLASS

and is used just the same as any Smith tube. This type of tube has been in use in our laboratory for some time and is found to be far superior to any fermentation tube at present on the market. By simply increasing the size of the bulb, it is possible to make tubes to contain quantities of inoculating water, of 50 and 100 c.c. Heretofore, no tube was available for 100 c.c. of water in one single inoculation.

The advantages of this type of tube are:

1. One piece tube
2. Requires no external support
3. Greater stability
4. Ease of handling
5. Not fragile
6. Less breakage
7. Increases the capacity of any incubator
8. May be manufactured in any size
9. Up to 10 per cent of gas is not lost in the arm if the tube falls over during incubation.

A SIMPLIFIED FLASK FOR RELATIVE STABILITY TESTS UPON SEWAGE

J. L. POMEROY, M.D., Fellow A. P. H. A.

and

R. V. STONE

County Health Officer, and Director of Laboratories,

Los Angeles County Health Department, Los Angeles, Calif.

IN 1915 Professor Ivan C. Hall¹ published a description of a new aerobic-anaerobic culture tube. This has become generally known as the "Hall tube." In principle, it is a modified potato tube, having a constriction about one inch above the bottom, this constriction being of a diameter that readily permits the sealing of the lower portion by a marble. Filled with nutrient broth, aerobic organisms propagate in the space above the marble, while anaerobic organisms grow in the space below.

During the development of this tube it was our privilege to be associated with Professor Hall, and we were familiar with tests conducted by him in proving the efficacy of his method. One test that was utilized to detect tubes where the marble seal was faulty was to introduce methylene blue into broth filled tubes and then to autoclave with the purpose of driving out dissolved oxygen in the lower chamber. As a result the methylene blue lost its color. These tubes were

then held for a considerable period of time for observation. Where color reappeared in the lower portion, such tubes were discarded as imperfect.

Several years later the writer had occasion to conduct an extensive series of relative stability tests and, since most methods in use involved considerable care in assuring a perfect seal on the sewage samples during the test, it was thought that utilization of the principle of the Hall tube should expedite such testing.

A stock flask was selected, this being the Baird sugar flask as illustrated in this article. The 100 or 200 c.c. Kohlrausch volumetric sugar flask with enlarged mouth can also be used, but this is not so desirable as the Baird flask.

New flasks as received in this laboratory are measured for capacity up to the marble seal, and the amount of methylene blue to be added for this volume is marked with a carborundum pencil into the glass. These are then tested by addi-

BAIRD INCUBATING FLASKS

tion of sewage and methylene blue to each, autoclaving and observing for complete decolorization below the marble seal. Any flask which does not maintain its condition of anaerobiasis is discarded, this in actual practice being seldom necessary. Ordinary glass marbles are used for the seal.

In making the test, the sewage sample is poured into the flask, which is held tilted so that the marble rests in the curve, leaving the neck open. Sufficient

sewage is used to bring the level about half way up in the upper section. The methylene blue is then added by means of a 2 c.c. graduated serological pipette. The marble is then allowed to roll back into place, effectually sealing the neck. The test is now ready to incubate at 20°C. exactly as in any other method. A cotton plug is used to seal the flask during the test. By introducing a methylene blue dosage in the upper portion after the marble has sealed the neck, a good color control on each test has been established so that the beginning of a partial decolorization in the lower test portion is readily observed.

Kohlrausch 100 c.c. flasks list for \$.50 each, while the Baird flask of 200 c.c. capacity lists for \$1.00.

NOTE: When using the Kohlrausch flask it is necessary to sterilize the marbles in a separate package, and after adding sewage and methylene blue to the flask, the marble is placed in the neck by means of a Stoddart test tube clamp which can be flamed if absolute septic technic is desired. *These flasks are very satisfactory for growing in broth 100 or 200 c.c. quantities of anaerobic cultures for preparation of antigens or bacterins.*

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

The Cause of Fetal Death—In this study 144 cases were examined, all but 3 of whom came from the Whitechapel district of London. In 39 of these the fetus was macerated; in 99, it was still-born but not macerated, and in 6 the fetus breathed for a short time.

Of the macerated fetuses, 14, or 35.9 per cent, were proved to be syphilitic by the identification of the *Spirocheta pallidum* in the tissues. Of the remaining 25, death in 11 cases was due to toxemia of pregnancy which was indicated by maternal albuminuria; 1 death was probably due to maternal morbus cordis; 1 death was possibly due to fetal malformation; in 12 the cause of death was obscure, but in only 1 case were the examinations sufficient to exclude maternal albuminuria.

In 91 of the 99 stillborn non-macerated fetuses the necropsy showed that the fetus had suffered from asphyxia. In 73 cases (approximately 73 per cent of the total cases) asphyxia was the ultimate cause of death. Of the 6 infants who breathed after delivery, there was evidence at necropsy of asphyxia in 4; in 2 there was no such evidence, but intracranial hemorrhages showed that one of the causes of asphyxia, excessive pressure upon the head, had been present. Taking all the cases of non-macerated fetuses together: in 105 cases, death was primarily due to maternal disease in 27, to fetal malformation or disease in 5, and to labor in 73. While spirochetes were found in 14 of the 39 macerated cases, they were found in only one of the 105 cases of non-macerated fetuses. Syphilitic infection was found in slightly more than 1 per cent of the non-macerated, in 35.9 per cent

of the macerated fetuses, and in 11.3 per cent of the total 133 cases examined for syphilis.—A. C. Palmer. Child Life Investigations. Great Britain Medical Research Council. *Special Report Series, No. 118*, 1928. 112 p.

Automobile Fatalities in the Urban Industrial Populations of American States, 1927—In 1927, 3 out of every 10 fatal accidents of all kinds in the industrial populations of the United States and Canada, resulted from the operation of motor vehicles. Reports for the first 5 months of 1928 show that this type of accidents is now occurring even more frequently than in 1927. Among Metropolitan industrial policyholders, the death rate for negroes, in 1927 was 17.2 per 100,000, as compared with 19.1 for whites. Comparison with a study of 1923 shows a 32 per cent rise in the automobile death rate among the negroes, as compared with only 16 per cent for the whites.

The death rate for Canada is 10.9 per 100,000 among whites, whereas that of the United States is almost double with 19.1 for whites and 17.2 for colored. But the rate in Canada has increased more rapidly in recent years. In the United States, the mountain states with a rate of 22 for whites, and the South Atlantic states with 22 for whites and 22.7 among colored, show the highest rate of automobile fatalities. The lowest rates appear for the New England states, 15.4 for white and 8.5 for colored, and for the West South Central states with 14.7 for white and 17 for colored.

Despite the immense motor vehicle traffic of the cities of New York State, the death rate 16.8 for whites and 14.9

for negroes, is well below the average for the country, and for the adjacent states of Connecticut, New Jersey and Pennsylvania.—*Stat. Bull.*, Met. Life Ins. Co. 9:6-8 (June), 1928.

Variations in Cancer Death Rates in Relation to Topography and Fuel—This study was based on three theories evolved by C. E. Green as a result of his investigations in the causes of the variations of cancer death rates in France, Scotland and England. These theories are summarized as follows: Open level districts of high or low altitude show lower rates than land in hollows or depressions or intersected by gullies, valleys or lying against adjacent hills. High rates from cancer accompany an excessive presence of SO₂ gas from the use of coal with a high sulphur content. Districts with uneven roof-lines have high cancer rates, because the resulting poor house and chimney ventilation increases the accumulation of SO₂.

Staten Island, in New York City, was chosen as the location for the survey because it presents a varied topography, and large parts of the island have suffered for many years from smoke, fumes and vapors from large industrial plants on the neighboring shores of New Jersey. The study was begun in November, 1920, and covered 515 cancer deaths among residents of at least 3 years for the period between 1914 and 1920. Adjustments for variations in diet and individual or parent nativity did not make any important changes in the rates. But the exposure to smoke fumes and gases from industrial plants or from coal stoves and hot air furnaces seemed to have a direct relation to mortality from cancer.

The rates for the 13 districts varied from 42.1 to 78.9 per 100,000 population. The 5 districts which were particularly exposed to the smoke from industrial plants in New Jersey all had

rates above 60. Only 2 districts that were not directly exposed had rates over 60, and these 2 districts, with rates of 69.6 and 76.3, were densely settled, level sections backed by high hills in which about 70 per cent of the population used coal stoves or hot air furnaces both of which methods of heating are likely to permit the escape of combustion products into the home. The 5 districts having the lowest rates, from 42.1 to 48.7 were only occasionally or indirectly exposed to the fumes of the industrial plants and, with but 2 exceptions, were sections in which at least 70 per cent of the homes used steam or hot water furnaces. The 2 exceptions were districts in which the majority of the people used coal stoves in which however a great deal of wood was burned, and the districts were so sparsely settled that there was little accumulation of fuel combustion products.

Variations in topography were somewhat less closely correlated to variations in cancer mortality. The 6 highest rates were found in districts with sloping or level land backed by hills, while the 2 lowest rates were in districts with level land. One section with high but fairly level land had a low rate, one with high sloping and intermediate land had a medium rate, one with comparatively level land had a fairly high rate, while one district which was considered fairly hilly, had a low rate.—Jerome Meyers *New York State J. Med.* 28:365-372 (Apr. 1), 1928.

Heart Disease in the Negro Race—From a study of 257 cases of heart disease admitted to Grady Hospital, Atlanta, Ga., it was observed that 3.7 per cent of all admissions to the general hospital were due to cardiac cases. Of the 257 cases with heart disease, 30 per cent occurred in the fifth decade, and 66.6 per cent occurred in the fourth, fifth and sixth decades. The incidence of

heart disease by decades is about the same in both the male and female groups.

Rheumatic heart disease is much more prevalent in the North than in the South. In the series of 257 cases 29.7 per cent were definitely syphilitic. From 20 to 25 per cent of negroes who contract syphilis sooner or later develop some evidence of cardiovascular syphilis. Among the cases of syphilitic heart disease 55.4 per cent had aortic regurgitant murmurs, and of this number 83.3 per cent were males.

Arteriosclerosis with hypertension or hypertensive heart disease without demonstrable arteriosclerosis, causes 60.1 per cent of all cardiac admissions, attended with high mortality. The disability is longest in the arteriosclerotic group, and it requires the longest hospitalization. The mortality is unusually high (44.8 per cent) because of the state of congestive heart failure in which these patients are received.—Hal M. Davison and J. C. Thoroughman. *South. M. J.*, 21:464-468 (June), 1928.

The After-History of Sanatorium-Treated Patients—The condition of 395 tuberculosis patients in the latter part of 1926 who had been treated in the King George V Sanatorium in the second half of 1922 has been traced. Of 384 cases of pulmonary tuberculosis, 35 per cent were dead, 20 per cent were capable of doing ordinary work, 9 per cent were doing some lighter work, 24 per cent were not able to work, 4 per cent were undergoing further institutional treatment and 7 per cent were untraced. When these were divided into T.B. + (cases in whose sputum the tubercle bacillus has been demonstrated on one or more occasions) and T.B. — (cases in whose sputum the tubercle bacillus has never been demonstrated),

the percentages were respectively: 39 and 13 dead, 18 and 30 doing ordinary work, 8 and 16 doing lighter work, 24 and 25 unable to work, 3 and 9 undergoing treatment, and 7 and 8 not found. There were 11 cases in which diagnosis of tuberculosis was not confirmed and of these 9 per cent were dead, 36 per cent were doing ordinary work, 27 per cent were unfit to work and 9 per cent were being treated. These figures compare favorably with sanatorium figures in 1914 and 1915, when 70 per cent of all cases treated in sanatoriums were dead in 4 years.

If these figures be divided into those representing the different periods of life, we see that the results remain remarkably constant. Of the T.B. + cases, the percentage of deaths between ages 16-24 was 42 and between 25-39, 40; and 40 and over, 35. Of the T.B. — cases, 10 per cent of the 16-24 age group were dead, 8 per cent of the 25-39 group and 21 per cent of those over 40. This appears to indicate that age has no very striking influence on the ultimate prognosis.

When the cases are subdivided by the Turban-Gerhardt classification, 16 per cent of those in stage I had died and 41 per cent were working. Of those in stage II, 21 per cent had died and 36 per cent were working and of those in stage III, 56 per cent had died and 16 per cent were working. If they are divided according to progressive degrees of systemic disturbance we find that 22 per cent of those in class A had died, 56 per cent of those in class B and 65 per cent in class C. On the whole the systemic factor is of more use in evaluating prognosis than the local disease extent factor.—C. O. S. Blyth Brook. *Tubercle*. 9:167-171, (Jan.) 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C.E.

Pollution of the Mississippi River in the Vicinity of Minneapolis and St. Paul—The basic data collected during a study of the pollution of the upper Mississippi River, between Minneapolis, St. Paul and Winona, Minn., collected during a joint investigation by the U. S. Public Health Service, the States of Minnesota and Wisconsin and the cities of Minneapolis and St. Paul, during the period June, 1926—August, 1927, have been made available, in mimeograph form, for the use of the coöperating agencies, to assist in the solution of the sewage disposal problem existing in that portion of the Mississippi River.

The report contains summarized results, as monthly averages, of the chemical and bacteriological examinations and hydrometric data. Population estimates, estimates of sewered population, population equivalent to industrial wastes and other pertinent data are presented.

The disposal of the sewage of the Twin Cities, by dilution, is complicated by a dam located below Minneapolis, behind which there is a considerable deposition of sewage solids from the city sewage as a result of decreased velocity in the river. The problem of the disposal of the sewage from the remainder of the metropolitan area will be still further complicated by the construction of a second dam in the near future, which will form a second pool immediately below the present one and will decrease the velocity in the river through St. Paul and South St. Paul.

Indications are that the sewage load in the river will increase so that objectionable conditions through the Twin Cities and as far down stream as Hastings will be of frequent occurrence in the future. The formation of the second

pool will intensify the present objectionable conditions.

Studies of methods of sewage disposal are being conducted by the Metropolitan Drainage Commission, created by the last legislature and by the Minnesota State Department of Health. It was primarily to make available the basic data relative to conditions existing in the river for the use of these state organizations, that the preliminary report was prepared—H. R. Crohurst. Unpublished report made under supervision of U. S. Public Health Service in coöperation with the States of Minnesota, Wisconsin and cities of Minneapolis and St. Paul. 86 pp. Abstr. H. R. Crohurst.

Public Works of the Ruhr Sanitary District—The Ruhr River Sanitary District was established by a Prussian law on June 5, 1913. Its sole purpose is to prevent pollution of the Ruhr River and its tributaries. The total population contributing is about 1,300,000. Industrial wastes are contributed by coal mines, iron and steel works, tanneries, textile works, and cellulose and paper works. According to the law, one-third of the cost of carrying on the work of the district is paid by the water works, since they are considered as receiving the greatest benefit.

Most of the construction work has been carried on in the last 4 years during which time total expenditures for the years were as follows: 1923, \$472,000; 1924, \$710,000; 1925, \$1,150,000; 1926, \$1,970,000; 1927, estimated, \$2,140,000.

The works consist of sewage disposal units, sewerage systems, and pump plants. To date 36 disposal units, 56.5 miles of collecting sewer and 5 pump plants have been built. For 3 towns

located near the mouth of the Ruhr, a collecting sewer 6.8 miles long was constructed which carries this sewage to the main stream, the River Rhein.

In other sections where it was impossible to divert sewage directly to the Rhein, various types of disposal plants have been installed. The methods of treatment used at various places are listed in this article and there are a number of photographic views.

Separate sludge digestion is used in one town of 16,000 and in another of 12,500. A sludge digestion tank in which the sludge is heated is used at one place. The sludge digestion tank was installed as an addition to the original Emscher tank. Heat is obtained by burning the gas from the treatment plant. Chlorination of sewage is used only to a limited extent. An activated sludge plant is used at Essen-Rellinghausen, population 45,000. There are very few treatment plants for handling industrial wastes alone and it has been the general rule to mix the wastes with domestic sewage and treat the mixture.—Karl Imhoff. Pamphlet in German, June, 1927. 8 pp. Abstr. A. L. Dopmeyer.

German Developments in Refuse Disposal—The developments of refuse disposal in Germany since 1893 are set forth briefly in this article. The shaft furnace in which heavy layers of refuse are burned was first developed at Hamburg. Other recent and successful developments are the removal of combustion residues by machinery, and in 1925 the installation of fire tube boilers in combination with the furnace unit. At the Hamburg plant, consisting of 12 furnace units, 4 of which are equipped with fire tube boilers, 1 of these units was replaced with a furnace provided with a grate residue remover and a vertical tube boiler. Tests on this unit indicate that it will handle 80 tons of refuse per 24 hrs. as compared to 30 tons per 24 hrs.

for the old units. Further successful developments along this line are an increased grate area, a slack-forming zone of water cooled iron surface covered with stone, the vibrating or oscillating blower, and the air heater. Combustion usually lasts about 20 minutes. The flue gases pass through the ashing chamber where they are burned further, and then successively through a fire tube boiler, a flue chamber with steam superheater, 2 horizontal flue-tube boilers, a second flue chamber, electric filter and chimney. The by-products of the plant are 45 to 50 per cent slack; 1 per cent old iron; 0.7 per cent magnetic slack; 5 to 20 per cent flying ash; 0.55 to 3.3 lbs. steam per lb. of refuse; 353 to 530 cu. ft. of hot water at 122° F. in 1 hr. from 1 furnace unit.—John H. D. Blanke. *Am. City* 38:87 (Feb.), 1928. Abstr. J. B. Harrington.

We Want Pure Air in Our Towns—The author feels that we should make an effort to furnish city dwellers with pure air just as we furnish them with pure water. On March 22, 1926, he says, two members of the French Academy presented the following analysis of material which fell on a gauge placed in the center of Paris:

Carbon	2,659	grs.	per	sq.	meter
Hydro-carbons	1,824	"	"	"	"
Sulphuric acid	2,432	"	"	"	"
Chlorine	0,253	"	"	"	"
Ammonia	0,021	"	"	"	"

A further analysis made at Vitry disclosed 1,592 kilograms of soot to the square meter during the month of February. He ascribes this latter figure to the use of coal rich in ash. The reaction of the distillation by-products of coal with Paris water which has been purified by chlorine is such as to produce an iodoform taste in the water sufficient to render the liquid at times undrinkable, according to the author.

A Draft Law has been brought before the Chamber of Deputies which will per-

mit the authorities to proceed to study this problem and remedy the present state of affairs. Louis Forest. *World's Health*, 9:86 (Mar.), 1928. Abstr. Leonard Greenburg.

Atmospheric Pollution With Arsenical Dust—This study arose because of a complaint that the dust from a power generating station was a nuisance and that it contained arsenic to the extent of 125 p. p. m. Accordingly, samples of dust were taken from the roof, rain water gutters and chimney shaft of the power plant and several factories in the neighborhood. The pulverized coal used at the power plant contained but 3 p. p. m. of arsenic, whereas the samples from the roof of the plant contained from 50 to 175 p. p. m.; from rain water gutters from 100 to 200 p. p. m. ; and from flue dust from 7 to 500 p. p. m. Despite the fact that the pulverized coal apparently contained so little arsenic, it is the author's belief that all of this arsenic originated in the coal being burned. It is pointed out that various types of coal may contain considerably larger amounts of arsenic than found here.

The question arises as to the health hazard brought about by the presence of this amount of arsenic in the furnace dust discharged in the atmosphere. It is conceivable that a workman might inhale more than that amount of arsenic which is specified as being the maximum permitted on imported apples. The requirements for apples at the present time specify that not more than 1/100 of a grain of arsenic per pound of apples is desirable. The author concludes that workmen engaged in cleaning out furnace flues would inhale more than this

quantity of dust, but there is no knowledge of any injury from this cause.

In conclusion, the author points out that the Public Health Smoke Abatement Act should tend to lessen atmospheric pollution of this nature.—G. Sowden. *J. State Med.*, 35:668 (Nov.), 1927. Abstr. Leonard Greenburg.

Sludge Thickening and Discharge—In some laboratory tests, it was found that the slow stirring of dilute suspensions of mud in water caused a concentration of sludge in 10 hours that was not equalled in 47 to 75 hrs. of quiescent settling. Tests were made with an experimental Dorr clarifier in which three methods of discharging sludge were tried: (1) discharge through a swivelled pipe which could be readily swung up or down to control the discharge head; (2) combinations of the swivel pipe and different sized orifices; (3) by the use of a diaphragm pump.

The conclusions drawn from the tests were: (1) The clarifier demonstrated its ability to thicken river mud and to discharge the sludge with a water loss of less than 1 per cent; (2) for the handling of this type of sludge, the piping should be free from shoulders or any obstructions; flange joints being recommended; (3) either orifice or swivel discharge may be used, but either will require careful manipulation and fairly close attention; (4) the diaphragm pump handled and controlled the sludge discharge without any difficulty, and could consistently remove sludge of a greater density than could be continuously discharged through an orifice or through the swivel pipe.—A. W. Bull and G. M. Darby. *Water Works*, 67:76 (Feb.), 1928. Abstr. H. B. Hommon.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH.D.

A New Test for Industrial Lead Poisoning. The Presence of Basophilic Red Cells in Lead Poisoning and Lead Absorption—According to this contribution, the action of lead and certain other toxic substances which affect the bone marrow, is to produce an out-pouring of miniature red cells from this tissue. These miniature red cells are thrown out in the circulation in an amount depending on the degree of irritation of the bone marrow. It is possible to distinguish the miniature red cell by its morphological and staining characteristics. Dr. McCord makes use of the fact that the miniature red cells contains basophilic material to provide a test for these cells. Thick blood smears are made on ordinary microscope slides and are dried in the air. Staining (without fixing) is done by means of a dilute, acidulated methylene blue or hypotonic saline methylene blue, or lastly by Manson's methylene blue. After 10 minutes of staining the excess is drained and the slide is washed in distilled water. It is dried and examined under the oil immersion lens without a cover slip. Red cells appear as a light ring of material while the basophilic cells possess granulated blue dots in a cell of reticulated nature.

The clinical studies on both normal (control) and exposed persons disclosed the following facts:

1. Normal persons usually have less than 1000 basophilic cells per cubic millimeter of blood, and always have less than 5000 such cells.
2. The number of basophilic cells is increased in lead, benzol and arsenic poisoning.
3. Frank cases of lead poisoning invariably present basophilic counts in excess of 7,000 cells, the usual range being from 7,000 to 50,000 cells.
4. Very high basophilic counts may be

present, as high as 60,000 to 80,000 without any signs of clinical lead poisoning.

5. Lead workers presenting basophilic counts in excess of 6,000 to 7,000, should be accepted in the absence of other causative agents as being poisoning subjects and should be treated accordingly.

The conclusions of this paper are based on a study of more than 1000 persons in various employments; of these 550 were lead workers exposed in varying degrees.

This would appear to be a very fundamental contribution and merits testing and use at the hands of those interested in lead and benzol poisoning.—Carey P. McCord, M.D. U. S. Department of Labor, Bureau of Labor Statistics *Bulletin* 460, Washington, 1928. L. G.

Occupational Mortality Among Males in England and Wales, 1921-1923—A Summary of the Report of the Registrar General—This is an abstract and digest of Part II of the 1921 Decennial Supplement of the *Report of the Registrar General of England and Wales*. It will be recalled that in 1912 the Registrar General published a report of a similar type dealing with occupational mortality during the years 1910, 1911 and 1912. The present report is similar to that of 1912, and is very thoroughly and comprehensively reviewed by Mr. Britten of the Statistical Office of the U. S. Public Health Service.

To one not familiar with this particular report of the Registrar General a hasty review would yield but a limited amount of information. The report is rather complex in nature and we are, therefore, particularly fortunate in having this excellent summary and digest prepared by Mr. Britten. It is impos-

sible to give the results of this digest in a brief abstract. Suffice it to say that the mortality rates are obtained with reference to social distribution, fertility and infant mortality, specific occupational groups with reference to major causes of death, mortality by age from a few of the causes in the larger occupational groups, a complete summary of standardized rates by occupation, and a comparison of these rates with the rates for the years 1910-1912.

The attention of all workers in the field of industrial hygiene and those interested in the vital statistics of occupation is invited to this paper.—Rollo H. Britten, *Pub. Health Rep.*, 43, 25: 1565 (June 22), 1928. L. G.

Cause of Occupational Dermatitis in Sydney Rubber Works in 1927—Studies in Industrial Hygiene, No. 11—Studies were conducted in two rubber factories manufacturing goods of such a type as to warrant comparison between the two plants. In one of these factories but 1 case of dermatitis had occurred among 250 employes in a period of 1 year. In the second factory during this same time there had been 136 cases of dermatitis among 1,500 employes. In this factory, designated as Factory B, 111 of the 136 cases occurred in shoe making, tire building and in the mill department which supplies stock for the whole factory. A comparison between the working processes and compounds used in the two factories revealed the fact that the excessive amount of dermatitis in this factory was due to the use of the three following substances:

1. The use of a butyraldehyde condensation product of dimethyl-paraphenylene-diamine as an accelerator.

2. The use for an isolated period of hexamethylene-tetramine as an accelerator for certain classes of goods which resulted in an outbreak of fissured palms and fingers in tire builders, due apparently to an unusual liberation of formaldehyde as a decomposition product.

3. The use of benzine for cleansing hands and arms.—

Charles Badham and K. R. Moore, Extract from the *Report of the Director-General of Public Health, New South Wales, for the Year ended 31st December, 1926*. Section I C. L. G.

Respiratory Diseases as a Cause of Disability Among Industrial Workers—This recent study of 10 years' illness and absence records of the Edison Electric Illuminating Company of Boston showed that some 54 per cent of the absences of men on account of sickness were caused by the respiratory group of diseases. A similar type of study made among the members of several industrial sick benefit associations disclosed the fact that some 47 per cent of all illnesses were in this group. From these studies it was found that when all cases of disabling sickness, as well as when only those cases causing a disability of one week or more were considered, the respiratory diseases constituted approximately one-half the total number of cases. It is obvious from this that for its effect on the absence rate, the respiratory diseases are of paramount importance.

A more detailed consideration of the respiratory disease absence rates of the Edison Electric Illuminating Company revealed the astounding fact that common colds account for 71 per cent of all of the respiratory disease cases. These, however, are of rather short duration, for when one considers the respiratory diseases causing disability for 8 consecutive days or longer the common cold practically loses its significance.

The seasonal trend of the respiratory disease follows the usual well known trend in the average community, the peak being in the months of January, February and March.

Some very interesting figures are cited showing the variation in the rate for

respiratory diseases among the employees of different industrial organizations, the rate varying from a maximum of 85 per 1,000 men employed to 17 per 1,000. The importance of this variation is clearly indicated by the author.—Dean K. Brundage, *Pub. Health Rep.*, 43, 11:603 (Mar. 16), 1928. L. G.

Industrial Poisoning Cases Among Watch Dial Painters—The effect of the use of radioactive substances on the health of workers using these materials in the painting of clock and watch dials, has recently been brought to the public attention once again through the lawsuit filed against the United States Radium Corporation of Orange, N. J. According to the present paper 14 girls who have been employed in this plant at various times since 1917 have died as a result of the absorption of radium. In addition, there have been 3 deaths reported among watch dial painters of Waterbury, Conn.

The case against the United States Radium Corporation was settled out of court with an agreement providing that each of the victims is to receive an immediate cash payment of \$10,000, an annuity of \$600, and an allowance for medical and legal advice. It is reported that one of the original workers with this substance, formerly an official of the United States Radium Corporation and the person who originated the formula for the luminous paint used in the New

Jersey plant, is at the present time a victim of radium poisoning.—*Month. Labor Rev.*, 27, 1:42 (July), 1928.

L. G.

High Death Rate from Pneumonia Among Iron Foundry Workers—In an analysis covering the 3-year period from 1922 to 1924 inclusive a particularly high death rate from pneumonia is indicated. This study shows that 15.9 per cent of all deaths among iron foundry workers insured by the Metropolitan Life Insurance Company were due to pneumonia, while 7.7 per cent among all occupied males were due to this same disease. The age distribution of the disease showed the same trend, being higher for each age of the chief working periods of life, from 15 to 64 years.

The study further discloses the interesting fact that of 74 occupational classes analyzed 15 had death rates in excess of that for all occupied males. The paper discloses the three distinct types of hazards associated with a high pneumonia rate, namely, dust, extreme heat, and exposure to sudden variations in temperature.

Some of the most significant groups having high pneumonia rates are iron, steel and foundry workers, cordage and hemp mill operatives, polishers on iron and steel products, underground coal miners, etc.—*Stat. Bull.*, Mar., 1928; Metropolitan Life Insurance Company. *Month. Labor Rev.*, 26, 6:51 (June), 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Blacktongue—Preventive Action of 16 Foodstuffs—The production in the dog, by certain diets, of a pathological condition regarded as identical with blacktongue, and its correction by an element present in yeast, appears in work previously reported from this laboratory (*Pub. Health Rep.* 41:297; 43:172 & 657; 40:54). The resemblance of this disease to pellagra in man and the fact that it is corrected by an element in yeast which is known also to contain the pellagra preventive (factor P-P) suggests the probability that these diseases are fundamentally identical. The blacktongue preventive action in the 16 foodstuffs here recorded was undertaken in view of the application of the information to the treatment of pellagra. Both curative and preventive procedures were used on the experimental dogs.

Details are given as to the duration of all feeding experiments, clinical symptoms and composition of the various diets with the following conclusion: Eleven foodstuffs—maize, wheat germ, cowpea, soy bean, milk, butter, cod liver oil, tomatoes, carrots and rutabaga—have been studied for preventive action, both in blacktongue and pellagra. In 8 of these—maize, wheat germ, cowpea, milk, butter, cod liver oil, lean beef, and tomatoes—the preventive potency for pellagra is similar to that for blacktongue. With the remaining 3—rutabago, carrots, and soy bean—the pellagra preventive action is not sufficient to permit comparison. It appears that so far as study has been made, all foodstuffs which are sources of blacktongue preventive are also dependable as pellagra preventive. Those which are defi-

cient in properties which correct the former disease are also poor sources for the prevention of pellagra. Of the remaining foodstuffs studied, whole wheat was found to contain the blacktongue preventive, but in small amounts. Cottonseed oil contains little if any blacktongue preventive. Pork liver and egg yolk contain blacktongue preventive, but their value in pellagra has not been studied. Canned salmon contains the blacktongue preventive. A study of its effect on pellagra is in progress. On the basis of experiments here recorded on dogs, it is recommended that liver, salmon and egg yolk be used for treatment and prevention of pellagra in human beings.—Joseph Goldberger, G. A. Wheeler, R. D. Lillie and L. M. Rogers, *Pub. Health Rep.* 43:1385 (June 8), 1928.

The Rôle of Aluminum Compounds in Animal and Plant Physiology—Previous investigators have reported widely varying contents of aluminum in animal and plant material. The fact that the early investigators reported the greatest amounts of aluminum in the same material has led to the belief that the refinement in analytical methods has resulted in considerable revision of our knowledge on this subject, and has raised the question if even recent figures are not higher than is actually the case. The wide distribution of aluminum in nature makes difficult the preparation of analytical reagents free enough from this element to be useful in biological assays. The authors have, therefore, had recourse to spectrographic methods of determining aluminum. The work was undertaken because of the widely divergent views of investigators at the present

time as to the effect of aluminum upon health, since these opinions vary—from those who regard it as a toxic element to those who regard it as a biological essential.

Spectrograms are shown of the various ash material studied. The authors found that various plant products; cereals, potatoes, carrots, and cottonseed meal; and animal products; hens' eggs and various organs of the rat, gave spectrograms in which no aluminum line was present, indicating less than 0.5 p. p. m. aluminum. The exceptions were rat skins, intestinal walls and lungs, which gave spectrograms indicating the presence of about 0.5 p. p. m. aluminum. The explanation is that these organs are absorbed.

exposed to air, dust and dirt, which are

Young rats, raised to maturity, on diets containing aluminum compounds compared in every respect to control rats under similar conditions but with the aluminum eliminated from the diet. Two experiments were undertaken—one in which the diet contained 0.6 per cent of aluminum chloride and in the other 3 per cent of a commercial brand of a sodium aluminum sulfate, calcium acid phosphate baking powder which had been decomposed by water and heat previous to feeding. The aluminum chloride and baking powder diets represented respectively 0.067 and 0.063 per cent of metallic aluminum. The growth curves and photographs of controls and tests show that rats receiving in the diet 600 p. p. m. of metallic aluminum in either form were the same in growth, reproduction, and general appearance as the control rats. A number of the young rats of both test groups were examined chemically after ashing the entire bodies of the baby rats and in the case of the older rats by ashing the individual organs. The ashes of the bodies of the baby rats and all of the individual organs, except the skin, lungs and intestinal walls gave

spectrograms indicating not more than 0.5 p. p. m. of aluminum in the various tissues. The skin, lungs and intestinal walls contained slightly more than 1 p. p. m.

To determine the degree of absorption by the intestines, rats were placed on control diet, and on the two aluminum diets, and spectrograms made of the intestines after thoroughly washing the tracts in distilled water. All spectrograms showed aluminum less than 1 p. p. m.; but neither of the methods showed more than in those on the aluminum-free diet indicating that the intestinal tract does not absorb or combine with the aluminum in the diet. The livers, kidneys, spleens, ovaries and testes of rats which had subsisted on test diet for 8 months were found to contain less than 0.5 p. p. m. of aluminum. The excreta of the rats, both control and on the diet, were examined for aluminum, resulting in all cases in an increased content of this element, further suggesting that the aluminum in the diet is excreted without passing through the walls of the alimentary tract.

This investigation indicates that while aluminum is not toxic, neither is it a biological essential so far as the rat is concerned. The results of this experiment confirm the findings of the Remsen Board of Consulting Scientific Experts which reported on a study on human subjects of the effects of diets containing biscuits baked with the sodium aluminum sulfate type of baking powder. It is proposed to continue this study with such biological, rare elements as manganese, zinc, boron and arsenic.—E. V. McCollum, O. S. Rask, and J. Ernestine Becker, *J. Biol. Chem.* 77:753 (May), 1928.

Iron Content of Plant and Animal Foods—The authors previously reported (*J. Biol. Chem.* 74:433) the iron content of certain tissues. In this paper are

reported the percentages of iron in about 150 samples of common food materials, fruits, vegetables, poultry and fish. Tables are given showing the iron content for each food product studied, ranging from 0.00015 per cent for lemon juice to 0.0192 per cent for parsley. This figure for parsley greatly exceeds any reported for spinach, a vegetable noted for its high iron content. Dried legumes were found to contain the highest percentage of iron, followed by green leafy vegetables, dried fruits, nuts, cereals, poultry, green legumes, roots and tubers, non-leafy vegetables, fish, and fruits. It was found that vegetables such as cabbage, celery and head lettuce, containing little chlorophyll, are low in iron. The soil and climatic conditions largely determine the iron content of plants, as is evidenced by the great variation in iron content of different samples of the same material. Salt water fish contain more iron than fresh water fish, and fish with dark colored tissues contain more iron than the light colored. Likewise, the dark meat of poultry is higher in iron than white meat. A comparison is given between the figures found in this experiment and those reported by Sherman (*Chemistry of Food and Nutrition* (3rd. ed.), 1926), which emphasizes the need of more analytical data on the mineral content of foods.—W. H. Peterson and C. A. Elvehjem, *J. Biol. Chem.* 78:215 (June), 1928.

Sanitary Quality of Some Commercial Milk Powders—One hundred samples of commercial milk powders obtained from groceries, bakeries and sim-

ilar places in Baltimore, representative of the city supply, were studied both bacteriologically and chemically. The bacteriological examination included plate counts, Breed counts, the determination of *B. coli* and search for the presence of the organism of tuberculosis. Both plate counts and Breed counts varied enormously, and the average respective counts from this source show a minimum of 1,000 to a maximum of 3,140,000 for the plate count and a minimum of 2,100,000 and a maximum of 37,000,000 for the Breed count. In no single case were viable tubercle bacilli found by guinea pig inoculation, and the *B. coli* count was in general around 5, with an extreme variation of 500. The chemical data included the total nitrogen and the per cent of this as ammoniacal and as amino acid nitrogen. A comparison between the Breed count and the nitrogen figures indicates an increasing amount of bacteria as the ammoniacal nitrogen increases. The amino acid nitrogen shows no constant relationship to the bacteria. The conclusions are drawn that the milk supply from which these powders were made was excessively high in bacteria and that proper sanitation does not obtain in the milk plant or in trade channels. From this work the authors are led to make the following statement: "Therefore, the finished product under the present conditions of manufacture and handling cannot claim to be the equivalent of the milk supply even when poorly controlled from the sanitary standpoint."—J. H. Shrader, C. L. Ewing, F. A. Korff and Lillian W. Conn. *Am. J. Hyg.*, 8:386 (May), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M.D.

Improving the Practice of Obstetrics—Dr. J. R. McCord, of Atlanta, has some definite ideas with regard to needed improvements in the practice of obstetrics. He insists that good obstetrics can be done in the home and is being done there without mortality and with a low morbidity, but he feels sure that obstetrics, being a science, calls for long and intensive training on the part of those who are to practice it. When individuals insufficiently trained attempt midwifery, lives are going to be needlessly lost and much unnecessary suffering caused.

To McCord there are two necessities for an obstetrician. One is a full knowledge of the mechanism of labor and the other is a bountiful store of patience. Soap and water, he says, together with a safety razor and a pair of rubber gloves, complete an ample equipment.

The general surgeon, in the opinion of the author, rarely has the accurate knowledge of the mechanism of labor that he should have, and consequently, "results in hospitals, if statistics are to be believed, are quite as deplorable as those in the home." The important point is not whether the patient is in a hospital, but who is attending her. He thinks that the ulterior motive behind painless labors is too often shorter labor for the physician. Lastly, he feels that "an outdoor obstetric service, at best but poorly supervised, is the wrong way to give men their practical experience in obstetrics."—*What is Needed to Improve the Practice of Obstetrics*, Dr. J. R. McCord, J. A. M. A., July 21, 1928, pp. 201.

Home Care of the Mouth—In the *Journal of the American Dental Association* is found a bulletin which is one of

a series on teeth and their care prepared for the information of the public. It is compiled by the American Academy of Periodontology. It sets forth that the intent of "home care of the mouth is to aid in protecting the teeth from dental decay; to preserve and promote the health of the tissues which support the teeth in the jaws; and to provide a clean environment for the masticating machine and also for the food which is prepared for digestion in the oral cavity."

This bulletin goes on to discuss various phases of hygiene of the mouth. It points out that a good set of natural teeth is of little use unless the supporting tissues are healthy. It advocates massage of the gums by the correct use of the tooth brush. It points out that faulty diet is a serious factor in diseases affecting the teeth and gums and recommends the usual modern well-balanced ration.

To accomplish results, all that is necessary according to this bulletin is (1) two small toothbrushes with two rows of tufts set fairly wide apart; (2) dental floss or tape of medium width; (3) dentifrices which, however, should not be relied upon to take the place of the proper use of the toothbrush; (4) mouth washes, which are not indispensable (A good one may be made by dissolving a level teaspoonful of salt in a glass of water); (5) a wall mirror for use in guiding the various steps in toothbrushing and taping; the mirror is also necessary to check up on results; (6) a clock to check up on time spent on the care of the mouth. A time allowance of not less than nine minutes a day is suggested for brushing and taping. Smokers and those who overeat should take longer. Extra

time should be taken for massage of the supporting tissues of the teeth. Where brushing is not feasible, as is often the case with office workers at lunch, the mouth should be rinsed thoroughly with water.

Various other good advice is offered in this bulletin concerning methods or technic.—The Home Care of the Mouth, *J. Am. Dental Assn.*, July, 1928.

The Danger of Serum Reaction—The fear is frequently expressed that injections of antitoxin and toxin-antitoxin may pave the way for unfortunate serum reactions if subsequent immunological procedures are undertaken. Dr. Sophie Spicer, in the *Journal of the American Medical Association*, gives the results of a study made on a series of 237 patients suffering from diphtheria and scarlet fever who received antitoxin at the Willard Parker Hospital in New York.

Care was used to study the histories thoroughly and information was obtained from parents of the patients concerning previous experiences with immunizing agents.

The conclusion to which Dr. Spicer comes is: "Previous administration of toxin-antitoxin appears to have little or no effect on subsequent serum treatment."

It should be said that one reason for the comparatively mild type of serum reaction which the author observed in her series was the giving of the antitoxin in small divided doses to patients who on test reacted for horse serum sensitivity.

It would seem that Dr. Spicer is right in her conclusion that clinicians as a whole have been overconcerned with the possible untoward results likely to follow

if serum is administered subsequent to previous doses of antitoxin and toxin-antitoxin.—The Effect of Previous Administrations of Antitoxin and Toxin-antitoxin on Serum Reaction, Sophie Spicer, M.D., Dr.P.H., *J. A. M. A.*, June 2, 1928, pp. 1778.

The Chief Causes of Deafness—"Almost half of a typical group of nearly 4,700 children of 12 years or over in certain representative schools for the deaf were reported as born deaf, and four-fifths were deaf before their 5th year, according to the National Research Council's report of its survey of schools for the deaf. Meningitis, scarlet fever, measles, falls and blows, and whooping cough are given as the chief causes of deafness which is not congenital."—*World's Children*, Children's Bureau, U. S. Dept. of Labor, July 3, 1928.

Speech Defects—Quoting from *Physical Education and School Hygiene Circular No. 12*:

Binet testing of children with speech defects in the St. Paul schools indicates that such children are neither duller nor brighter than other children. The median I.Q. for 402 children was 97.7—just average.

The percentage of children with each type of speech defect differs with the age groups. Letter substitution is found mainly in first and second grades. The percentage drops steadily until the junior-high-school age, when the defect is rarely found. Stuttering and stammering, on the other hand, are defects acquired, rather than lost, during the school career. It is practically the only defect at high school age.

There are about 400 pupils enrolled in the speech correction classes in a school population of about 40,000.—

Physical Education and School Hygiene Circular No. 12, U. S. Dept. of the Interior, May 7, 1928.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

The Heart Disease of Childhood—
Syphilis and senile degeneration are responsible for a large part of the heart disease appearing in adult cardiac clinics. Syphilitic heart disease is preventable if as soon as the disease is contracted treatment is instituted and continued.

The third largest group of patients have rheumatic heart disease. The last is essentially different from the first two forms, as the disease occurs almost exclusively in the first half of life. Because this is true, a very definite challenge to prevent rheumatic fever or its after-effects is offered to those interested in the care and well-being of children.

Until the exact nature of rheumatic fever is determined, at some future time, it would seem the safer plan to treat as one and the same condition the well-defined, clear-cut cases of rheumatic fever and the child who has growing pains, who is in poor health with recurring colds and sore throats, and who may or may not have signs of cardiac involvement.

The proper treatment and management of such children may do much to prevent the occurrence of rheumatic heart disease.

Every safeguard possible should be taken to lessen the strain on the heart of any child recovering from rheumatic fever or from any acute infectious disease. Children should not be allowed out of bed too early. The following points may make it easier to determine when the child may be permitted increased activities:

1. Normal body temperature for a week, not varying more than 1.5° F.
2. Maximum basal rate not more than 100 a minute
3. Return of pulse rate to previous resting basal rate within 3 minutes after exercise
4. Progressive gain in body weight
5. Absence of signs of fatigue, such as

- a. Lack of appetite
- b. Irritability in the late afternoon
- c. Delayed or restless sleep
6. Normal white blood cell count
7. Normal red blood cell count
8. Normal systolic blood pressure
9. Pulse pressure of 50 mm. or less
10. Heart size, stationary or decreasing
11. Normal cardiac mechanism
12. Absence of signs of heart failure
13. Normal respiratory vital capacity
14. Absence of skin eruptions
15. Absence of rheumatic nodules
16. Quiescence in infections of nose, throat or other foci
17. Period of normality for two weeks after withdrawal of salicylates.—

Rheumatic Heart Disease, by Hugh McCulloch, M.D., *J. A. M. A.*, 90, 26:2073 (June 30), 1928.

Deafness in Children—The infectious diseases are condemned as being responsible for many cases of acquired deafness. Records show that the most dangerous period of the development of deafness in children is before the 3rd year, that age when children are so apt to contract the familiar diseases of childhood.

In a group of over 1,000 deaf children, meningitis, scarlet fever, measles, influenza, infantile paralysis, and suppurative otitis media, were responsible for about 40 per cent of the cases. Infections of tonsils and adenoids, a factor in producing a mild deafness in children, are not regarded as being responsible for the production of deafness. Where deaf children have had tonsilleotomies, the charitable view to take is that these were done not because of the deafness but because of the unhealthy condition of the adenoids and tonsils.

If the incidence of the infectious diseases is decreased, deafness in children

will be diminished to an appreciable extent with the accompanying economic and social gains. B. J. B.—Deafness in Children, *J. A. M. A.*, 90, 26:2104 (June 30), 1928.

New Things in Medicine—Is there “nothing new under the sun”? The old, familiar quotation answers us in the negative. Yet the year 1927 brought about some notable discoveries in medicine. Among these are the successful treatment of paresis by inoculating the patient with malaria. The fever thereby induced can destroy the paresis germ, and the malaria may then be cured by quinine. An apparently crystalline form of insulin was produced. The drug “myrtilin” was announced to be a treatment of diabetes. An antitoxin to cure erysipelas was developed.

Pernicious anemia is no longer the hopeless disease it was once, since the effectiveness of the Minot and Murphy liver diet has been demonstrated.

A diet for treating epileptic children has been found.

Another weapon against rickets in babies was discovered in the use of dried milk treated with ultra-violet light.

The good work is still going on. What will 1928 bring forth?—New Things in Medicine, *Ohio Health News*, 6, 13:4 (July 1), 1928. B. J. B.

What Next?—The death rate of women in childbirth can be lowered; the death rate of infants can be reduced. That the Sheppard-Towner Act has brought about these results is the conclusion drawn by the American Child Health Association and the Maternity Center Association from a study made by them at the request of the League of Women Voters to evaluate the accomplishments made under the Maternity and Infancy Act.

The maternal death rate for the

country *as a whole* has not changed appreciably in 1926 from that in 1922 when the act was inaugurated. However, during that period, the maternal death rates in the country districts have diminished; those in the city have increased. As most of the Sheppard-Towner money has been spent in rural districts, it is but fair to assume that it is in some measure responsible for the reduction.

Among the direct results of the bill may be numbered the formation of child hygiene bureaus in many states which previously had none, the establishment of permanent health centers, and the distribution of literature. Work is varied according to the needs of the state; for example, in Minnesota the Indians have received a much needed service from trained Indian nurses; child health conferences were conducted by physicians for Indian children. In Pennsylvania where large numbers of foreign born women demand delivery service by women rather than men, instruction has been given to midwives.

Such widespread activities must arouse interest in what is being done and what remains to be done. If the Sheppard-Towner Act has done nothing else, it has increased interest in maternal and in infant welfare.

The work is not completed. Many communities yet need to be shown by demonstration the reasonable standard of care for mothers and their babies. The effective methods of education must be made available through more and still more health centers and through conferences. The Sheppard-Towner funds will no longer be available after June 30, 1929.

What will then be the country's response so that the thousands of mothers yet unreached may receive the instruction and help they need?—The States Account for Their Stewardship, *Child Health Bull.*, 4, 3 (May), 1928.

Independence Assurance—Every professional self-supporting woman likes to feel that she will be able to continue to support herself regardless of advancing years. Life insurance can make this independence possible.

In considering the best form of life insurance for them, nurses may be divided into three groups: the nurse who does not have to support herself entirely, the one who supports herself and contributes to the support of others, and the nurse who has only herself to consider.

In the first case, the necessity of life insurance as a means of independence assurance is, obviously, slight.

In the second case, the nurse needs to consider the loss of income to her dependents through her death or loss of earning capacity. For her, many plans are possible, depending on the purpose to be served. If the largest amount of insurance at the minimum expense is desired, ordinary life insurance best fills the need. This guarantees an estate at the time of death, larger than any other contract carrying the same premium deposits. It is possible by the payment of slight additional premiums to have double indemnity if the insured is killed by accident. Likewise, an increased premium may pay for financial assistance if total or permanent disability should occur. Certain other desirable features are obtainable.

In those cases where the beneficiaries are only partly dependent for support on the one insured, the nurse might find it more advantageous to assume that form of contract which gives herself more return, such as a long-term endowment policy or one affording life income payments.

The nurse having only herself to look out for may find a series of endowment policies maturing at different times an exceedingly satisfactory way of insuring

independence in her later years, as well as providing funds for travel or other purposes. A retirement annuity, designed particularly for professional people, guarantees the payment of a monthly income when a certain age is reached.

It is only possible to indicate some of the ways in which a nurse may anticipate her future needs. Any representative of the insurance world would be ready to find the form of insurance best adapted to the personal needs of every nurse.—Charles J. Fay, *Insurance for Nurses*, *Am. J. Nurse*, 28, 6:579 (June), 1928.

Each Kind Necessary—"There are three kinds of public health work," said Sir Arthur Newsholme. "There is *first*, the old-fashioned public health work, for a large part of which we are immensely indebted to the engineering profession: the getting of a pure water supply, of adequate sewage and drainage, and the protection of food supplies. The stage of building up the sanitary regulations, generally defining such work has been gone through with. And these regulations need to be continued as much as ever.

"There is, *second*, the kind of public health work which views it with utmost importance that the consequences of physical defects be forestalled by their prevention and eradication in infancy and in early childhood.

"And, *lastly*, there is the form of public health work which recognizes it as a public duty that health protection and medical treatment be provided when persons needing such protection and treatment, or their families, are otherwise unable to secure it."—Sir Arthur Newsholme Revisits the New York Health Demonstrations, *Quarterly Bull. Milbank Memorial Fund*, VI, 3:54 (July), 1928.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Wanted Before October, 1928—Outlines for the year's program of health organizations—local, state, national—public department or private agency—or outlines of specialized programs, such as, the inauguration of a new piece of work, diphtheria immunization, attendance at a clinic, vacation precautions, etc. Selections from the outlines submitted will be mimeographed and used in the discussion of "Steps in Preparing a Program of Health Education and Publicity," at Chicago in October.

The outlines should answer these questions:

1 Why will you undertake what you are planning? What facts, circumstances, or desires lead to the choice of activities?

2 What results are sought? What are the objectives or the responses hoped for?

3 To whom will you address the messages? What groups or kinds of people will you try to reach as being most important in getting the results wanted?

4 What is to be the message—the chief talking points—in each special activity?

5 How will you approach the selected groups or kinds of people? What do you believe to be their attitude toward the subject, and their understanding or lack of understanding of the subject? What motives, such as fear, the desire for good looks, civic pride, etc., will be appealed to in seeking action?

6 What are to be the methods and materials used in handling the several situations? List what you will do and what forms of publicity you will use. (A set of samples for display would be welcome.)

In addition to the above please list the routine activities, such as, day by day news which does not relate definitely to the program of effort for the year, the bulletin or house organ, giving out printed matter or information on request, etc.

7 Supplementing the above it will be useful to make up a calendar showing what is to be done month by month in both the preparation and carrying out of the publicity activities.

Recently several health and other social agencies have laid out their year's work according to the above outline. The results have been fairly startling. *We believe that you can do nothing more helpful in preparing for 1928-1929 than to make such an analysis of the plans for the year ahead.* If you cannot prepare a full statement, go as far as possible. Please send your outlines as early as possible to Mrs. Mary Swain Routzahn, 130 East 22nd Street, New York, N. Y. Will you drop a line stating that you are on the job?

Education and Publicity Headquarters at Chicago—The space allotted is bigger and better than we have ever had at the A.P.H.A. There will be room for consultation and conference, and the displays will have enough space so that they can be seen.

Division One: Ideas, methods and illustrative specimens—what to do and how to do it—ideas in the rough and ideas worked out in detail.

Division Two: Specimens of leaflets, folders, pamphlets, placards, posters, etc., etc. issued in 1927-1928 and choice specimens issued at any date.

The classification of the displays will be most satisfactory if the material is mounted, as noted below, except items that are too large or too heavy.

Heavy Kraft (brown wrapping) paper will be good for the purpose. Use one side of sheets cut not larger than 11 by 14 inches (11 being the width). Try to leave blank about 2 inches at the

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

left. If you get the sheets punched for binding have 3 holes, standard distance, at the left.

Every subject or method of use should be on a different sheet so that both the mounted and unmounted material may be classified after it reaches Chicago. Examples: Diphtheria, Colds, etc., etc., Annual Reports, Postal Cards, For Teachers, Mimeograph Work, Programs of Meetings, etc., etc.

If the name of the city and of the organization does not appear plainly on the material, please write, print or paste it at the top of every sheet. Explanation or comment, uses, number used, costs, etc., may be added where convenient by pasting a slip on the sheet.

All the items used in a campaign (newspaper, money raising, legislative, clinic attendance, etc.) may be grouped on several sheets with name of campaign at the top, or may be mounted in a binder.

In some cases, groups of closely related items could be mounted on cards not larger than 22 by 28 inches (22 being the width).

The headquarters display will also include helps in producing publicity material and information for those preparing publicity, which will be classified under such headings as: Paper, Printing, Statistics, Contests, Office, Exhibit Devices, etc., etc.

Items especially desired: the posters of the year; picture diagrams; organization charts; newspaper cartoons; photographs used in newspapers or printed matter; good newspaper stories; campaign outlines and handbooks; photographs or descriptions of stunts or features or window displays; examples of linoleum block illustrations, blue print process posters, soap sculpture; ideas, devices or materials which may be used in preparing exhibits or other publicity matter. Arrangements can be

made to show film slides and other projection material.

Send shipments *prepaid* to reach Chicago by Friday, October 12, and addressed to Evart G. Routzahn, Hotel Stevens, Chicago, Ill. Advance correspondence should be addressed to the above at 130 East 22d St., New York, N. Y. Material will be returned only if so requested in writing.

Join—or Get Them to Join—Before Chicago—The one professional organization for those doing any phase of public health education work or supervising such work is the Public Health Education Section of the A. P. H. A. The investment of the \$5 membership fee will mean far more to the health worker than to the A. P. H. A. which receives it. Why not canvass your staff for any who are at all concerned with any phase of education and publicity and invite them to join? Why not write to the health agencies in your city and state? The A. P. H. A. will gladly supply application blanks, but your letters need not wait for these. Write your first letters and if any do not respond, follow up with the blanks.

We All Take Part at Chicago—Luncheon sessions will be enriched by the ideas and experiences of many workers from all sections of the United States and Canada. Under "High Spots in 1927-1928," we hope to have time enough for quick reports of all the new ideas and successful methods, with mention of bright news stories, etc. We expect "Ray" and "Al" to demonstrate a duet on social hygiene before Kiwanis, and possibly others will have displays. What have you to offer? If, sadly enough, you cannot be at Chicago, please send samples or descriptions to be presented for you. In response to requests, one luncheon will show "Why Some of the Exhibits at the Convention

Are Good"—and possibly why some are not so good. What is new in "Diphtheria Campaigning" will follow up the Cincinnati session, when the audience was much too big for the meeting room. The "Program for Health Education Training in Teachers' Colleges" will be of significance to our educator members.

Getting Together at Chicago—The "live wires" in public health education and publicity will be largely represented at Chicago in October. The mere coming together of the supervisors and practitioners of successful publicity, even if there were no formal meetings, would make the trip well worth while. Ideas, experiences, questions as to how you did it, brief cases overflowing with samples, stimulating personalities—all will await your arrival at Chicago. And the Dinner-Business session of the Public Health Education Section, Tuesday night, will be the grand get together opportunity of the year.

What About the Audience?—We have seen the speaker whose face and manner made clear that he was almost unconscious of his audience as a group of people, and heard the speaker who reveals his ignorance of what the members of his audience know or feel about the subject. According to Bertram G. Nelson, University of Chicago, what you say depends on your estimate of the audience. Prof. Nelson, speaking of dental talks, says:

Bring them vividly before your mind. Ask yourself such questions as these: 1. Are they boys? Girls? A mixed group? 2. How old are they? 3. Have they any interest in teeth now? 4. Would a girl's interest in her teeth have the same basis as a boy's? 5. Have they had experience with dentists? 6. Do they like dentists? 7. What home training have they had in caring for their teeth? 8. Has the school taught them anything about their teeth? 9. How much can they receive in ten minutes? 10. What obstacles must be overcome? 11. Have they any prejudices that I need to overcome? 12. Has any other dentist

been there before me? If so, did he make a good or bad impression? 13. What are the fundamental facts that have a practical application for them?

Try talking about his teeth to the next high school boy that you meet. Don't begin by giving him good advice but question him. Find out at first-hand what boys of his age think about their teeth, and what care they give them. You will think this step is unnecessary and will try to remember what you thought and did at that age. Don't fool yourself. Talk directly to the present high school boy. Don't judge him by your own son or daughter. Your children were brought up in a home where toothbrushes were a religion. Talk to your boy's pal. Talk with several boys. After you have interviewed five or six boys and girls, notice how definite your image of that high school assembly has become. Already you begin to feel somewhat at home with it.

Do You "disseminate knowledge"?—"Briefly, the control of cancer depends mostly upon the dissemination of knowledge that will lead to its early recognition by the patient and the physician."—*Health*, New Hampshire State Board of Health. Are we disseminating knowledge, or handing out printed matter? There is often a difference.

To Prime the Pump—In the search for a title for a pamphlet the publicity worker of a national organization looked over a variety of folders and booklets. Then he wrote: "I found several suggestions which may prime the pump." The frequent collections of titles and other groups of material are given in this department largely to stir the imagination of alert workers—to stimulate thinking—to "prime the pump." Additions to these lists are always welcome.

ADDRESSES AND PRICES

To save space we do not give addresses or prices of periodicals with every reference. Usually this information will be given somewhere in the issue, except in the case of the most widely known publications. If not, it will be found in this department in a recent issue.

COÖPERATING GROUPS

Not long ago a high school wrote to the American Junior Red Cross: "Don't give us something to read; give us something to do." And it is "something to do" that will win for public health the active coöperation of millions of helpers—children, young people, grown-ups. *What do we offer them to do?* The editor of this department offers a very special prize for the "best" list of services asked of non-health groups which is submitted before the Annual Meeting in Chicago.

If Rotary, or any club or school group you wish to interest gets out an illustrated year book, tell them of Warren's Year Book Portfolio with its very practical suggestions for business manager and editor. It is good also because of its layout suggestions, for any group which issues an annual report or other publication containing many pictures of clubs or other groups. S. D. Warren Co., 101 Milk St., Boston. *Free.*

Fifteen luncheon clubs will be addressed by representatives of the American Dental Association during the August meeting in Minneapolis, Minn.

"Women's Clubs and State Health Program" is a news release of Illinois Department of Public Health. Tells of help given by various coöperating groups.

HOUSE ORGANS

Child Health Bulletin, American Child Health Association, gives two interesting forms of diagram to show when babies die, and the main causes of their death.

The Commonhealth, Massachusetts Department of Public Health, describes the "teacher's own health score card," prepared by a committee of the Massachusetts Teachers' Federation.

Health, New Haven Department of Health, gave a page for the New Haven

Library to tell about the "readable books for the laymen" that are available.

The Health Bulletin, North Carolina State Board of Health, is quoting liberally from current newspapers and other periodicals, sometimes with snappy localized comment.

The Health Messenger, is a 16-page monthly now issued by the Public Health League of Washington, 907 Medical and Dental Bldg., Seattle, Wash.

Social Hygiene News, American Social Hygiene Association, outlined the work of the Division of Public Information and Division of Educational Measures in its March 30 issue.

A dainty valentine design on the cover page of the last February number of *Better Health*, Department of Health, Syracuse, N. Y., enclosed these words: "Mother Dear—If you love me as you say you do, please have a health examination every year and see to it that I have one also. Don't let Dad forget his examination either. Your Valentine."

Two new periodicals are announced in a recent issue of one of the especially helpful magazines for health workers, but no addresses are given!

"Popular Health Education in the Orient," by Dr. F. Humbert. *Worlds Health*, Dec., 1927. Brief reviews with illustrations. "The fundamental principles of popular health education being one and the same, variations of local details are of no more importance than the color of the clothing or skins of natives."

Health Bulletins for the people—We have received several bulletins from an eastern city which are illustrated by an exuberant cartoonist and written by a deadly serious health officer. If they could meet half way—or still better, get together on the premises of the artist, the everyday people for whom they are intended would learn more.

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

WITH Congress in adjournment, the Supreme Court in recess, and the executive branches of the Government subject to the somewhat enervating summer climate of Washington, there has been a vacuity of items on public health law from the national capital. Not so in the states, however, as the following items from Indiana, Massachusetts, Georgia, Missouri, Wisconsin, New York and Virginia will show.

A City Pays for Stream Pollution

—It has cost the City of Frankfort, Ind., damages amounting to \$3,962.07 for polluting a stream with sewage and thus causing injury to an individual property owner. A decision upholding such an award by a lower court was handed down by the Appellate Court of Indiana on June 19, 1928, according to the *Monthly Bulletin* of the Indiana State Board of Health. In this case, *City of Frankfort v. Slipper*,—Ind.—the city attempted to show that since it was authorized by statute to build and maintain sewers, it could also lawfully discharge its sewage without purification into a stream which is the natural outlet, and that there could be no liability from such action. The court, in an able opinion, declared:

The rule of necessity thus declared must in and of itself inevitably force just the opposite doctrine, in the interest of the public health, the very thing supposed to be subserved by the rule, when it is daily becoming more and more apparent that the sewage in the streams is a real menace to the public health, and it is not a necessity, because it can be otherwise provided for, with practicability and assured safety to the public health.

A violation of the Federal Oil Pollution Act by a steamship captain on the Taunton River near Fall River drew a

fine of \$500 imposed on June 1, 1928, by a United States District Court in Massachusetts, according to an article by Dr. George W. Field in *Our Dumb Animals* for July, 1928. Dr. Field writes that the judge in this case "rendered a distinctly notable service to humanity and to the world in general."

Another Milk Ordinance Upheld

—The Supreme Court of Georgia is the latest of the state courts of last resort to sustain a city ordinance for the sanitary control of milk. On May 5, 1927, this court, in the case of *Leontas v. City of Savannah*, 138 S. E. 154, construed the milk ordinance of that municipality, but did not actually pass upon its constitutionality. On April 16, 1928, this same court handed down an opinion in the case of *Leontas v. Walker*, 142 S. E. 891, in which the constitutionality of the ordinance was upheld.

The facts in this case are rather unusual. Leontas, a dairyman, was indicted for involuntary manslaughter because of the death of a person who drank chocolate milk containing condemned milk from the Leontas dairy. The indictment alleged that Leontas was engaged in an unlawful act, violation of the city milk ordinance, when the death occurred. Leontas was thereupon bonded to appear for trial, but went to Europe. His attorneys came to court and attempted to file a demurrer to the indictment, alleging among other things that the ordinance in question was unconstitutional, but Leontas not being present, the court refused to accept it, and later ordered payment on the bond. Leontas appealed.

The Supreme Court merely held that the ordinance was not inconsistent with

the constitution of the state, saying, "The power to 'regulate' the sale of milk includes the power to 'prohibit' the sale of impure milk as referred to in the ordinance; so that, in substance, the ordinance only involves one subject matter."

In New York, a judge of the Court of Special Sessions, one of the lower courts, has held unconstitutional a regulation of the New York City Sanitary Code which prohibits possession of a churn or other device for treating milk, without a permit from the Board of Health. This regulation was held to be unreasonable, because it is the *use* and not mere possession which might be dangerous. *People v. Schneider, et al.*

A Real Guide for Health Officers

—A number of unique and particularly valuable features characterize the *Health Officer's Guide* recently issued by the State Board of Health of Wisconsin, where Dr. C. A. Harper is State Health Officer. Not only does this booklet reproduce accurately the state laws on all phases of public health, but it also contains opinions of the Attorney General, abstracts of court decisions pertaining to public health from many states, and discussions of the legal aspects of various health subjects.

The laws, which comprise the latter half of the book, are printed directly from the same plates used for the state code. While this plan causes the page numbers to be peculiar, this slight disadvantage is more than offset by the fact that the laws are given correctly, which is more than can be said for many pamphlet compilations of laws prepared by state health departments.

Since other states may contemplate the issuance or revision of similar booklets, a few constructive suggestions may be in order. The opinions of the Attorney General are presented here in the middle of the book, with apparently no

special arrangement. An endeavor should be made to key such opinions to the laws to which they refer. Many of the court decisions have no references at all, and none has more than one citation. The value of these abstracts would be greatly enhanced if dates of the cases were given, together with complete references to all law reporters where the cases may be read in full. Consultation of the table of nearly 500 cases in the book, *Public Health Law*, shows that there are at least three references each for most of the decisions listed. The cases in the Wisconsin pamphlet might also be arranged in a more logical sequence.

Among the other useful material in this health officer's guide are descriptions of the functions of the divisions of the state board of health, discussion of the organization and duties of local health authorities, suggestions for local action, model ordinances and local sanitary regulations, and the rules and regulations of the state board. Although there is a good index, a table of contents would also have been valuable. The arrangement of topics might also be better.

Although a few opportunities for improvement have been pointed out, the general idea and execution of this guide is excellent, and it is a work which should be of great value to health officials in Wisconsin, and of interest to sanitarians in administrative capacities in other states.

The Buzz Saw—"Don't monkey with the buzz saw," says Pennsylvania's *Health* for July-August, 1928, in reporting that a citizen of that state was recently prosecuted and convicted for permitting her children to be on the public highway after the premises had been quarantined for scarlet fever. She had the further honor of policemen at her front door to see that the quarantine was observed.

A similar incident occurred recently in New York, according to an editorial printed on July 3, 1928 in the *New York Sun*, which frequently comments in a progressive manner on public health matters. A man who had smallpox took an automobile ride. It cost him \$100 fine for his folly. Another person quarantined for smallpox decided to wander away, but when he was found he was arrested, convicted, and permitted to languish in jail for 30 days. "The health officers mean business when they impose quarantine," says the *Sun*. "They do not play with death. The public they seek to protect from its own recklessness and lack of information should learn to obey their orders." Good advice!

Virginia Also Takes Action—Mr. Rutzahn has passed on to this department a mimeographed news release from an unknown source, dated July 6, 1928, which states that a prominent physician of Charlottesville, Va., has been fined \$25 for failing to put nitrate of silver drops in the eyes of an infant whose birth he recently attended. The child developed an eye infection, though blindness was averted by prompt medical care by other physicians. It is said that the parents of the child contemplate an action for damages. All this is hearsay, but it emphasizes the good advice, "Don't monkey with the buzz saw of public health."

A reprint from the *Southern Medical Journal* for June, 1928, entitled "Public Health Administration in Virginia," which contains no hearsay, but a number of solid facts, will be sent by the Associate Editor, or by Dr. E. G. Williams, State Health Commissioner, Richmond, Va., to anyone who cares to have it.

"Court Work" and Venereal Diseases—In New York City all women who have been convicted of street walking are referred to the Department of

Health for examination by a physician. Those found infected are sent to a hospital, though old offenders and recidivists go to the workhouse. During 1927, a total of 2,481 such persons were examined and 1,190, or 48 per cent, were found infected, according to an item in the *Weekly Bulletin* of the New York City Department of Health for May 26, 1928.

"Menace of the Half Man"—Judge Harry Olson of the Municipal Court of Chicago contributed a brilliant paper on crime and mentality before the Third Race Betterment Conference at Battle Creek, Mich., last winter. An abbreviated report of this address is presented in *Good Health* for July, 1928, and should be read by all persons interested in this important subject.

Judge Olson points out that defects of the emotions are conspicuous to a remarkable degree among the unreformable and dangerous criminals. He describes the psychopathic clinic connected with the Boys' Court in Chicago, to which judges send suspected cases of mental defect. Out of 779 such cases, 654 were found to be suffering from dementia praecox, 109 from psychopathic constitution, and 10 from epilepsy. Dementia praecox was also discovered to be the leading criminal psychosis among persons brought before the Morals Court and the Domestic Relations Court.

One solution proposed by Judge Olson to the problem is to give psychiatric examinations to all school children, so that defectives may be identified and the unreformable type segregated. In order to do this, however, many more experts are needed.

Infantile Paralysis Delays a Trial—A man charged with unlawful possession of intoxicating beverages applied for a writ of habeas corpus on the ground that he had not been given a

speedy trial. The writ was denied because it was shown that there was an epidemic of infantile paralysis in the town where the court sessions were held and therefore a delay of more than 60 days was excusable. This is a California case, *Ex parte Venable*, 261 Pac. 731.

Report Births or Be Fined—Missouri was admitted to the birth registration area in September, 1927. Since that time 2 physicians to whom this fact apparently meant nothing, have had the pleasure of paying fines for failing to comply with the state law on vital statistics, according to an item in the *Journal of the American Medical Association* for July 21, 1928.

Miscellaneous Items—An International Conference on the Safety of Life at Sea will be held in London in the spring of 1929 to bring up to date the 1914 convention.

A survey of public health administration in the District of Columbia has recently been completed by the U. S. Public Health Service. The local health department is said to be "inadequate and ineffective in many of its component activities."

Cuba has a new law imposing a tax on luxuries, the revenue of which will go to tuberculosis hospitals and other public welfare institutions.

Health work in Soviet Russia is described in the *Monthly Labor Review* of the U. S. Department of Labor for July, 1928, the article being a lengthy review of a recent book on this subject by Anna J. Haines.

A Florida law for the regulation of the practice of pharmacy, which is now under the supervision of the State Board of Health, is given in the *Health Notes* of Florida for July, 1928.

The police power is the subject of an interesting article by L. P. Stryker in the *New York State Journal of Medi-*

cine for July 15, 1928. Mr. Stryker, who is counsel of the medical society, is contributing a series of articles in the legal department of this magazine.

CONFERENCES

September 12-14, Southern Conference of Tuberculosis Secretaries, Biloxi, Miss.

September 17-19, Mississippi Valley Conference on Tuberculosis, Des Moines, Ia.

September 18-21, New England Water Works Association, Montreal, Can.

September 24, 25, 26, New England Health Institute, Burlington, Vt.

September 25, 26, Annual Conference of Indiana State Health Officers, Gary, Ind.

September 25, 28, American Roentgen Society, Kansas City, Mo.

October 1-5, National Safety Council, New York, N. Y.

October 4-6, Association of Military Surgeons of the United States, Baltimore, Md.

October 11-13, Fall Regional Social Hygiene Conference, Louisville, Ky.

October 11-13, Canadian Public Health Association, Winnipeg, Can.

October 11-13, International Association of Dairy and Milk Inspectors, Chicago, Ill.

October 15-19, American Child Health Association, Chicago, Ill.

October 15-19, American Social Hygiene Association, Chicago, Ill.

October 15-19, State Health Officers of Illinois, Chicago, Ill.

October 15-19, American Public Health Association, Chicago, Ill.

FOREIGN

October 29-November 1, Second International Conference on Light and Heat in Medicine, Surgery and Public Health, London, England.

December 28, International Congress of Tropical Medicine and Hygiene, Cairo, Egypt.

BOOKS AND REPORTS

Publicity for Social Work—By *Mary Swain Routzahn and Ewart G. Routzahn*. New York: Russell Sage Foundation, 1928. 392 pages. Price, \$3.00.

Publicity is an essential aspect of successful social work. Whether one considers securing financial support for an organization, creating public demand for better social legislation, arousing sentiment against undesirable social conditions, or persuading the individual to "Cross Crossings Cautiously," the weapon upon which success depends is publicity. This volume is a manual of publicity technic.

The authors admit that they had expected to be able, after their detailed examination of publicity programs in many organizations and communities, to indicate the fundamental principles of successful publicity. Their studies, however, revealed the fact that there is no commonly recognized or scientifically organized technic for publicity among social service agencies. This treatment, accordingly, undertakes to set forth as an integral part of its analysis the psychological principles underlying effective publicity. Throughout the text the authors bring, from a wide scope of material, the findings of technical research and scientific investigations.

The discussion is by no means theoretical, however, for it keeps close to the material afforded by the experience of actual organizations. Such topics as "Social Work and the Newspaper," "Printed Matter," "Meetings," "Dramatic Methods," "The Intensive Campaign," suggest the range of interest.

The psychological and educational material is sound and to the point. The problems discussed are practical, and there is a wealth of valuable detail. An abundance of illustrative material from

widely varied sources lends both interest and concreteness. The book represents a genuine contribution to the field.

FORREST WITCRAFT

The Newer Knowledge of Bacteriology and Immunology—*Edited by Edwin O. Jordan and I. S. Falk*. Chicago: University of Chicago Press, 1928. 1196 pp. Price, \$10.00.

This book does not purport to be a text, nor yet a comprehensive survey of the whole field. It is "an attempt to make the latest results of investigation in various lines of bacteriology and immunity available for students and active workers." The editors state that it is their hope that the book will serve to promote research both by furnishing landmarks of progress and by affording suggestions on significant unsolved problems. The book partakes of the nature of a symposium, a type of work quite popular at present. The first portion is largely devoted to bacteriological matters and the latter portion to immunology.

So far as suggestiveness is concerned those chapters on immunological subjects are distinctly more stimulating to the worker and come more nearly to filling the claims of the editors than the chapters on bacteriology. The former are often mere reviews, largely of a text-book nature, only a relatively small portion of the material being "newer." In approximately one-third of the book there are more than a hundred references to literature prior to 1900. Inasmuch as the book is inconveniently large, much of the older material, which may be found in standard texts, might well have been omitted. Certain chapters might also have been combined without appreciable loss to the value of

the book—for example, I on morphology and IV on morphological changes during growth, V on growth curves and VI on the rise and fall of bacterial populations, XXIII on soil microorganisms and XXVI on the relation of organisms to soil fertility, and several others. Other chapters have little relation to the title or the subject, such as XXXIII, which, though excellent, treats entirely of the mechanical aspects of pasteurization.

Perhaps the chapters of most value to the worker in pure bacteriology are those which seem to have least connection. Chapters XII on oxidation-reduction potentials, XLI, which treats of the general aspects of filterability, and X on atoms, ions, salts, and surfaces contain information which, though not in itself especially new, is important since the recognition of such subjects as affecting bacteriology is not of long standing.

Certain chapters might well be omitted. Chapter XXX on bacteria in milk is largely the history of the confusion in nomenclature of certain milk organisms. In reading chapter XXXI on bacteria in dairy products, which is filled with general non-technical information, one gets the feeling of being superficially escorted through an industrial plant, or in reading chapter XXXIV on foods, one is reminded of the advice of a retained technical expert to a layman.

Certain chapters are stimulating and give specific suggestions for handling problems. Especially so are Norton's two chapters on water bacteriology and on the action of ultra-violet, and Tanner's chapter on yeasts. On the other hand, one reads too often statements similar to that of Kahn on page 857: "numerous problems in connection with the nature of the reaction are yet to be solved," though the nature of such problems is not disclosed.

Two or three points of confusion which have been rather common in recent literature have been retained in

the book. In at least two places (pages 19 and 1115) the authors confuse pH with acidic or basic properties of a compound. This confusion seems much more general than it should be and often leads to misconceptions and misinterpretation both of one's own data and of published results. Physical units are at times confused, as on page 373, where energy is expressed in watts.

The book has several rather serious omissions for a work of its claims. There is practically nothing included on cytological problems. A reading of chapter VII will indicate the importance of cytology, an aspect in which modern researches on dissociation have stimulated renewed interest. Despite the personal opinion of an author regarding receptor analysis, it should certainly be given more than simple mention.

In several places the reviews do not seem quite up to date. Two cases are the omission of reference to the theory of fermentation of A. L. Raymond (*Proc. Natl. Acad. Sci.*, 11: 622, 1925) in connection with a discussion of theories of fermentation in chapter XVI, and omission from chapter XI of mention of the important work of Gibbs, Batchelor and Sickels (*J. Bact.* 11: 393, 1926), on the effect of surface tension on bacterial growth—a piece of work which leads to conclusions not in accord with those given by the author of this chapter in his own work. One can hardly accept the statement in this chapter that if union between toxin and soap is chemical, "all toxins reacting with a given soap would necessarily be considered identical chemically."

On page 303, the footnote is in error. These methods were not officially approved by the Laboratory Section of the American Public Health Association, and the Standard Methods Committee is not authorized to approve such procedures; therefore the statement that such approval was given is an error.

There is great lack of uniformity in structure of chapters, not only in the text but also in the references. The name is not quite broad enough to cover the subject matter treated since there are chapters on yeasts and molds and protozoa. Many of the chapters one would wish to have available, but one might not wish to be forced to acquire the entire book for those chapters, especially since more than a few have such similarity of structure and content to single articles or books by the same authors, that reprints would serve the same purpose and be less unwieldy to use. A proper grouping of the chapters into several volumes which might be purchased separately would be an improvement.

As a whole, the book is exceptionally free from typographical errors. The only one noted which is likely to be taken as an error of text is a sign of one of the values for free energy change on page 324.

M. P. RAVENEL

Proceedings of the Tenth Texas Water Works Short School—Austin, Tex.: Texas Section of the Southwest Water Works Assn., 1928. 300 pp. Price, \$1.00. 40 per cent off on 10 or more copies.

The volume is divided into two sections, one devoted to Water and the other to Sewage and covers 294 pages. The two subjects are rather fully gone into, considering that the material was prepared for a 4-day program which had to represent the varied interests of the water and sewage plant operators in Texas. The papers were prepared by some of the foremost men in their respective fields in America and foreign countries.

H. W. Streeter of the U. S. Public Health Service discusses filter plant loadings and stream pollution; microscopic life in water is treated by Dr. Asa Chandler of the Rice Institute, Houston,

Tex.; Dr. Karl Imhoff tells how he calculates the capacity of sludge digestion tanks; Arthur J. Martin, consulting engineer of London, discusses activated sludge problems from the English standpoint; while G. L. Fugate and J. C. McVea, engineers of Houston, Tex., disclose some of the secrets of a successful activated sludge plant in Texas as exhibited by the Houston installation. Dr. Willem Rudolfs, of New Jersey Experiment Station fame, points the way toward a comprehensive sewage research program for Texas.

The special water problems of Waco and St. Louis are discussed by a water superintendent and a water commissioner, respectively, who have had charge of their plants for a number of years. Some of the recently installed and especially interesting sewage plants are described and illustrated, including that at Fort Worth, Houston, Jacksonville, and Waco.

E. G. EGGERT

Water Purification—By Joseph W. Ellms, (2d ed.) New York: McGraw-Hill, 1928. 594 pp. Price, \$7.00.

It is somewhat over ten years since the first edition of this important volume was issued by Mr. Ellms. At the time of its first appearance it contained approximately 485 pages of an excellent summary of water purification practices and devices, as of that date. It was written in simple style, reasonably well illustrated and with presentation of tabular and graphical material, helpful to the general, as well as to the technical, reader.

The second edition, as well as the first, contains information of value to the public health profession. It reviews the classification of natural waters, the principles of transmission of disease through drinking water, the effect of improved water supplies upon health and the detailed procedures and mechanisms of treatment by which the removal of

various objectionable constituents is accomplished. It has been and should continue to be one of the few modern authoritative and fairly comprehensive texts on water supply treatment.

The reviewer is somewhat in doubt as to whether the volume in hand may be logically designated as a second edition. After careful survey of its contents, one finds that it is virtually the first edition repeated verbatim with additions almost entirely restricted to new bibliography, photographs and short portions of new text inserted bodily within the old, and frequently merely added to existing chapters. New material is presented on the strainer systems of filtration plants, mixing devices prior to coagulation, the manufacture of aluminum sulphate, discussions of motors, efficiency and cost of operation of rapid sand filters, the effect of hydrogen-ion concentration of natural waters (a new chapter), on disinfection of water (in some minor additions to the chapters), the application of iodides in the treatment of water (one page), and in the amplification of discussion on water softening, boiler compounds, recarbonation and iron removal. The additions are of interest and helpful, but their introduction into the bodies of the text, frequently without any adjustment of previous text, leaves something to be desired.

The issuance of a second edition in the form followed in this case leads to some disconcerting inconsistencies, as, for example, in Chapter 29, page 451, where it is stated that "Chlorine or the hypochlorites are, therefore, merely agents for the production of oxygen under conditions which render it extremely active." Somewhat the opposite conclusion is indicated on page 480, in Chapter 30, where at least some doubt is indicated as to the oxidation effect of chlorine compounds in disinfection and otherwise. The inconsistency probably

has its origin in the fact that the earlier chapter has undergone virtually no changes in language over the edition of 1917. The same criticism applies to the bulk of the present edition.

Unfortunately some of the typographical errors of the first edition are carefully repeated in the second.

Although approximately 17 pages are devoted to power plant pumping machinery, etc., in Chapter 23, the wisdom of including such material in this text is debatable. It is hardly possible to devote sufficient space to the topics included therein to make them either authoritative or comprehensive. The discussion in two pages of motors for centrifugal pumps hardly does justice either to the subject matter or to the author.

The text still represents one of the most valuable sources of reference for information on water purification practice. The criticisms do not refer primarily to the fact that the second edition has made the first less helpful, but that it might have made it more helpful, with more complete revision of text. It is possible, for instance, that the discussion of the state of the art in ozone, ultra-violet light and algicide treatment does not require any change in a text 10 years old, in order to give an accurate picture of present-day practice, but the reviewer has some doubt about it.

ABEL WOLMAN

Heredity and Human Affairs—By Edward M. East. New York: Scribner, 1928. 325 pp. Price, \$3.50.

Professor East is not only an authority on the phenomena of heredity and genetics, but a thinker with a clear insight into the significances of investigations in this important field and a writer with a facile pen, some knowledge of literature, and a sense of humor. His latest book dealing with heredity in relation to human traits and human problems is therefore authoritative, up-to-

date, very lucidly written and withal quite entertaining.

Among his chapters are those dealing with the grammar of heredity; heredity and sex; inheritance of human traits; heredity and environment; marriage between near kin; racial traits; race problems; genius; mediocrity, and education; the lower levels of humanity; the survival of the underman; and immigration.

His advice on cousin marriages is caution, because of the prevalence of objectionable recessive traits, particularly defective conditions of the nervous system, in man. Inspection of family histories is advised before such marriages.

In matters of education, he pleads for more attention to, and more expenditure on the more intelligent child, and for better teachers. Segregation and sterilization are the effective means of restricting the increase of the worst types of human defectives, but much may be done with the higher grades of defectives, the morons, the neurotics and the intermittently insane, by educational measures. Dr. East is not sanguine that social inadequacy will ever be eliminated by any combination of eugenics and euthenics, but does suggest that the disastrous results of a bad heredity combined with a bad environment may be mitigated by the panaceas dear to the heart of the social worker.

He is less optimistic than Pearl with regard to the effect of the declining birth rate of the professional and related occupational classes in our population. East points out that superiority is not the result of mutations, but is rather due to fortunate combinations of desirable genes. Eugenics and genetics are not all "blather." The extinction of families supplying such genes in larger proportion will have its effect in time.

Immigration in recent years has tended to lower the quality of the national stock. When forced by economic

necessity it tends to lower the biological quality of the race and immigrant competition tends to sterilize the native population.

The relation of the unintelligent to art, science, and civilization is seen in anti-evolution agitation, anti-vaccination propaganda, and anti-vivisection societies. "Science will be hounded, coerced, and suppressed, possibly destroyed" by such agencies. Social reforms are not panaceas. The epigram of the London *Spectator* on the "Modern World" is in point:

Science finds out ingenious ways to kill
Strong men, and keep alive the weak and ill—

That these a sickly progeny may breed,
Too poor to tax, too numerous to feed.

Genetics gives fair warning to the sensible that civilization is in a dangerous situation, for which only one remedy is specific. CHARLES A. KOFORD

School Posture and Seating—A Manual for Teachers, Physical Directors and School Officials. By Henry Eastman Bennett, Ph.D. New York: Ginn, 1928. 320 pp. Price, \$2.00.

This book is a combination of a discussion of posture from an anatomical and a physiological point of view, a report of a study of sitting posture of school children and a description of a method by which the author has arrived at his conclusions of what constitutes a proper school seat.

All three parts are treated scientifically, with the possible exception of the study of the posture of school children where the objectivity of the author's tests might be questioned. There is no doubt that a chair in which a school child can sit correctly is important; but this importance seems a bit over-emphasized in the discussions on the results of bad posture. The appearance of our "girl graduates" each June suggests an exaggeration in the following statement: "The universal occupation of girlhood

is 'going to school'; and here, despite the insistent reiteration of school hygienists, despite the fact that posture habits established in this formative period almost inevitably affect the whole future physical life, figures prove posture to be extremely bad."—and can we rely absolutely upon these figures? And still again there is no proof that school sitting posture permanently affects the habitual posture of children.

Modern practices in education give much more freedom in the schoolroom than formerly, and children do not sit in one seat for long periods of time. And again, flexibility of the spine and general muscle tone have more to do with habitual posture than the chairs on which we sit.

The book as a whole is a very valuable contribution to the subject of posture, and Mr. Bennett takes a broad view, but it must be kept in mind that posture is a complicated subject with no evidence as yet by which we can determine whether it is a cause or a result of many of the disorders discussed in this book. The type of seat described in detail coincides with studies made by the American Posture League and all who have responsibility in the seating of school children should read this book.

ETHEL PERRIN

Proceedings of Fifth Annual Short School, Texas Association of Sanitarians—*Houston, Tex., Nov. 1-4, 1927.* 136 pp. Price, \$1.00.

This pamphlet containing 144 pages is divided into six sections. The first covers numerous questions, among which might be mentioned discussions of the field of non-medical sanitarians, Texas schools and sanitation; practical epidemiology, railroad safety campaigns and housing.

The second section is devoted entirely to milk sanitation. The status of this work in Texas and Louisiana is dis-

cussed. Bacteriological tests of water and algae are treated in the third or laboratory section, while section 4 covers sewage disposal and related subjects like privies, septic tanks and stream pollution.

Section 5 is devoted to mosquito control and means for financing such work. The proceedings and minutes of the meeting are contained in the last section.

ARTHUR P. MILLER

A Sound Economic Basis for Schools of Nursing and Other Addresses—*By Mary Adelaide Nutting, R.N., M.A. Putnam, 1926.* 372 pp. Price, \$2.50.

In a series of published addresses given at various times over a period of 22 years, Miss Nutting presents much of the history of the struggles to provide the sick with better nursing care through the advancement of education for nurses. These addresses are now collected in one volume.

Anyone reading this book cannot but be impressed by the sympathetic way in which the problems are treated; by the rare and deep compassion for the sick and a firmly rooted desire to provide them with intelligent, skilled, efficient care; sympathy for the administrative officers of the hospital; and understanding of the difficulties of the graduates who are unprepared many times for the wider fields of professional life, entering, as they do, into every level of society.

The establishment of the proper relationship of the hospital to the school of nursing is stressed. The latter should exist solely for the purpose of educating the nurse. Trustees or managers willing to accept the responsibility of providing funds for maintenance and for its growth and development, should be vested with the power to control and manage the school.

To the ever-present urgent problem of

financing the schools is apportioned much space. Three ways of securing funds are offered for consideration; namely, through public funds derived from taxation, private funds by gifts, and fees from students.

The ideal school of the future will have university affiliation; endowment fees paid by the students with liberal provision for scholarships and local funds for those who are unable to meet expenses; a shorter course for college graduates; high entrance requirements; sound instruction in the preliminary sciences; adequate libraries and equipment; shorter hours on duty; time for rest and vacation; more capable paid

teachers, and self-imposed discipline. The endowment can provide for all, but in order to secure endowment funds the public must first be acquainted with the real need of the school.

A wealth of experience in educational and administrative fields qualifies the distinguished author to speak authoritatively on questions relating to the present inability of schools to advance to a place where nursing education is comparable to that which is offered in other professional schools.

The book amply substantiates the arguments in favor of the fundamental need of the schools of nursing.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Scientific Movies—Pitfalls encountered in the production of surgical movies should be of interest to those who contemplate the making of motion pictures dealing with health.

ALBEE, F. H. Science goes to the Movies. *M. J. & Record*, 128:1 (July 4), 1928.

Gonorrheal Vaginitis—The record of admissions to a child-caring institution shows gonorrheal vaginitis more prevalent in winter and spring than in summer and fall. The preponderance of chronic to acute infections is shown.

BLUM, J. Gonorrheal Vaginitis of Infants as a Seasonal Disease. *Arch. Pediat.*, 45:6 (June), 1928.

Immunity in Scarlet Fever—Three papers dealing with scarlet fever, offering evidence and suggesting explanations for this phenomenon: skin sensitivity is lost much more quickly than antitoxin is produced in the blood following prophylactic treatment or following the appearance of the rash during the disease. The importance of hypersensitiveness as a factor is stressed in propounding the hypothesis that the disease is due perhaps to a protein poison rather than a toxin.

COOKE, J. V. Scarlet Fever. *Am. J. Dis. Child.*, 35:6 (June), 1928.

College Athletics and Longevity—A statistical study of the lives of 5000 college athletes (from 1880 to 1905) which indicates that the group studied presented a favorable mortality picture. It is the author's opinion that athletic activities in the loosely supervised earlier period did some damage.

DUBLIN, L. I. Longevity of College Athletes. *Harpers* July, 1928.

Neurologic Infections—A summary of what is known of the epidemiology

and etiology of epidemic meningitis, poliomyelitis, and epidemic encephalitis. As valuable as the name of its author would promise.

FLEXNER, S. Obvious and Obscure Infections of the Central Nervous System. *J. A. M. A.*, 91:1 (July 7), 1927.

Heart Disease Prevention—Another of the multitude of British papers on heart disease and rheumatism. There is probably nothing very new or startling in this one.

FORDYCE, A. D. The Prevention of Heart Disease. *J. State Med.*, 36:7 (July), 1928.

Oral Typhoid Immunization—A review of the results of about a half million vaccinations *per os* against typhoid fever. The theoretical advantages of Besredka's method are discussed.

GARBAT, A. L. The Oral Method of Prophylactic Typhoid Immunization. *M. J. & Rec.*, 128:2 (July 18), 1928.

Chicago Communicable Disease Survey—A committee report of a survey (with criticisms and suggestions) of Chicago health department practice in regard to the control of communicable disease, school hygiene, sanitation, education, etc.

GERSTLEY, J. R., et al. Survey of the Communicable Disease Situation in Chicago. *Am. J. Dis. Child.*, 35:6 (June), 1928.

A Hundred Years of Epidemiology—This paper is the first dealing with the history of epidemiology in Great Britain containing many useful references and quotations for the writer upon health topics.

HAMER, W. H. History of Epidemiology. *Lancet*, 1:26 (June 30), 1928.

Plural Nature of Vitamin B—Irradiated vitamin B carriers lose their growth-promoting factors but retain

their anti-neuritic properties; autoclaved specimens have the reverse characteristics. Used together, they supplement each other.

HOGAN, A. G. and HUNTER, J. E. The Plural Nature of Vitamin B. *J. Biol. Chem.*, 78:2 (July), 1928.

Mental Hygiene—This rather general outline of the possibilities of mental hygiene as a public health function would make an excellent introduction to a book. It lacks suggestions of method.

HILL, T. W. Mental Hygiene and the Child. *Pub. Health*, 41:10 (July), 1928.

Measles Prophylaxis—Additional evidence is offered that Tuncliffe's anti-measles goat serum will prevent measles if given early and modify the disease if given any time during the incubation period.

HOYNE, A. L. and PEACOCK, S. Prevention and Modification of Measles with Antimeasles Diplococcus Goat Serum. *Am. J. Dis. Child.*, 35:6 (June), 1928.

Ricinoleated Vaccines Again—A very brief and pointed note answering Kozlowski's contention that ricinoleic acid causes abscesses and hence should not be used. The author points out that the material purified with barium, as used by Kozlowski, was discarded several years ago and that the type of material used in ricinoleated vaccines causes no ulcerations.

LARSON, W. P. Ricinoleated Streptococcic Vaccines. *J. Immunol.*, 15:4 (July), 1928.

Rural Medical and Nursing Service—The methods by which medical and nursing services are subsidized in the highlands and islands of Scotland are recounted for the benefit of the frontier nursing service of Kentucky.

MACKENZIE, L. Medical and Nursing Service. *Lancet*, 2:3 (July 21), 1928.

Etiology of Encephalitis—Is epidemic encephalitis caused by toxins from organisms in the respiratory or gastrointestinal tract, a cultivable bacterium,

or a filtrable virus? Although most research points to the latter, the author concludes that the etiology remains unproved.

NEAL, J. B. The Present Status of the Etiology of Epidemic Encephalitis. *J. A. M. A.*, 91:4 (July 28), 1928.

Official and Unofficial Relationships—An interlocking directorate by which tuberculosis associations may be made to work harmoniously with the health department and the medical society is proposed. A very worth-while suggestion.

NELBACH, G. J. Fundamentals in Tuberculosis Work with Respect to Voluntary Unofficial Associations. *New England J. Med.*, 198:18 (June 21), 1928.

Liquid Petrolatum and Digestion—Studies of fecal elimination by dogs and human subjects indicating that liquid petrolatum does not interfere with the digestion and absorption of food.

OLSEN, A. B. Effect of Liquid Petrolatum Given by Mouth on Digestion and Absorption of Food. *J. A. M. A.*, 91:3 (July 21), 1928.

Grains and Vegetables in Diet—Experiments are reported indicating the advantage of using whole grains without increasing costs of diet. A freer use of vegetables raises amounts of vitamins, increases laxative properties, and promotes assimilation of iron. Further experiments are recorded indicating the value of eggs when added to otherwise balanced diets.

ROSE, M. S., and MCCOLLUM, E. L. Studies in Nutrition. *J. Biol. Chem.*, 78:2 (July), 1928.

The British Milk Supply—An interesting round-table discussion of milk supply supervision in Great Britain. The introducer discusses "milk as a food and milk as a poison," and quotes someone as saying he'd as soon see graded water as graded milk.

WYNNE, F. E. Present Position of the Milk Supply. *J. Roy. San. Inst.*, 48:1 (July), 1928.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Bellevue-Yorkville Health Demonstration—The annual report for 1927 consists of four parts, an historical summary, an account of the year's activities, a statistical report of volume of work, and a financial statement. A study of school medical inspection in the 24 schools of the district, a study of stillbirths, and a study of street accidents have contributed basic information of considerable interest. Accidents of all types in the district are responsible for more than 10 per cent of the general mortality. Campaigns for the prevention of colds (32,000 pieces of literature distributed), and of diphtheria (3 months' intensive drive for immunization, 31,000 pieces of literature and 2,300 posters distributed, among other activities), and many other health education measures are described. Several important clinics have been opened.

During the year, there was a total attendance at the various clinics and services of 32,488, of which 12,921 visits were to the baby health station, located within demonstration headquarters. There was also an attendance of 18,559 at the 646 meetings held at headquarters for educational purposes. Of the 46,756 home care visits made in the district by the agencies located in headquarters, 21,330 were directly for bedside care and generalized nursing service by the Henry Street Settlement, 12,593 home care visits by the Department of Health nurses, for infant welfare (4,885), control of contagion (3,835), and tuberculosis supervision (3,875). Detailed statistical tables conclude the report.

San Diego, Calif.—In 1927, a population of 114,900, a birth rate of 23.7, and a resident death rate of 13.9 (not

corrected 18.2), are recorded for this city. An infant mortality rate of 60.6 is compared with a rate of 46 for the previous year, 99 of the 165 infant deaths occurring in the first month of life.

During 1927, there were reported 977 personal injuries resulting from motor vehicle accidents occurring in the city, as compared with 1,039 the previous year. Of this number, 282 were pedestrians. A total of 35 persons were injured in automobile and street car accidents as against 54 in 1926. There were 37 deaths from this cause as compared with 46 the previous year. The noted improvement is encouraging in view of the efforts made during 1927 to reduce the number of automobile accidents, by the traffic commission, the police department, the courts, the public safety committee, the local press and others.

The child hygiene division report includes 55 prenatal clinics with 279 attending, 93 well baby conferences with 2,538 attending, 696 prenatal nursing visits, 363 maternity visits, 878 visits to sick babies, 320 instruction visits, 465 emergency visits and 44 Little Mothers' classes.

Rockefeller Foundation—The president's review for 1927 contains a stimulating account of health activities in many lands. A list of 20 of these activities indicates the broad scope of the Foundation's interest: aided in local health organization in 85 counties of 6 states in the Mississippi flood area; operated an emergency field training station for health workers in this region besides contributing toward the support of 9 other training centers elsewhere; assisted 9 schools or institutes of public health and 3 departments of hygiene in university medical schools; gave aid to 17

nurse training schools in 14 countries; supported the Peking Union Medical College; paid 2 million dollars toward a new site for the University of London; helped Brazil to maintain precautionary measures against yellow fever; continued studies of that disease in West Africa on the Gold Coast and in Nigeria; had a part in malaria control demonstrations or surveys in 8 states and 11 foreign countries; aided 19 governments to bring hookworm disease under control; contributed to health budgets of 268 countries in 23 states of the American Commonwealth and of 31 similar governmental divisions in 14 foreign countries; helped to set up or maintain public health laboratory services or divisions of vital statistics, sanitary engineering, or epidemiology in the national health services of 19 countries abroad and in the state health departments of 16 American states; made grants for mental hygiene work in the United States and Canada; provided funds for biological research in universities; helped the League of Nations to conduct study tours or interchanges for 125 health officers from 44 countries, to supply world-wide information about communicable diseases, to train government officials in vital statistics, and to establish a library of health documents; provided fellowships for 864 men and women; made appropriations for improving the teaching of premedical sciences, and for expenses of hospitals in China, and for equipment and literature for medical centers; lent staff members as consultants and made surveys of health conditions and of medical and nursing education in 14 countries.

In discussing the relation of private agencies and public authorities, this significant statement is made:

Under anything like normal conditions the voluntary health association does its best work when it keeps always in mind the aim of strengthening the official organization of the community. Every private agency should be only too glad to turn over to an efficient health

department a service or activity which has been built up by voluntary effort. To be sure, it may be at times the duty of a private association to attack openly an incompetent or politically corrupt health administration, but ordinarily friendly support of even a weak official will prove a sound policy. To express confidence that he is going to do the right things will help him to meet expectations.

It is interesting to learn that Yugoslavia requires of every medical student 6 months' service with a department of health. In considering the training of doctors for a new era, it is emphasized that the idea of preventive medicine will never fully prevail until more doctors enter the field as leaders, until physicians in general understand and actively support public health activities and until they themselves seek to keep people well through periodic examinations and by advice about personal hygiene. "If this is ever to happen, medical schools will have to change their courses and their attitude."

Association of Tuberculosis Clinics, New York, N. Y.—The 1927 report shows on the inside cover the location of the 15 clinics in the various districts of Manhattan. The membership of this voluntary organization includes 29 tuberculosis clinics which function either under municipal or private organizations. In general, the activities are confined to clinic and home work among the tuberculous and the exposed families of these patients. The objects include the promotion of clinic control of tuberculosis in the city, the development of uniform methods of operation and the provision of equally efficient care throughout the city, the elimination of duplication, the keeping of patients under observation until satisfactorily cared for either in a sanatorium or hospital, the gathering of uniform statistics, the coordination of activities, and the assistance of the department of health in its control of tuberculosis.

Important studies were carried on during the year. More than 16,000 children were treated in these clinics in which more than 37,000 persons were examined, among whom were 9,362 cases of tuberculosis. The clinic attendance was 93,356, of which number 36,891, or 1 out of every 3, were visits by children. In addition, more than 46,000 home visits were made by the clinic nurses to tuberculosis cases or their families, and 9,608 more to social or medical agencies on behalf of clinic patients. The data for these clinic patients and services are analyzed in detail and valuable statistical tables are included.

Miami County, O.—The population of this county health district in 1927 was estimated as 26,502, with only 0.4 per cent colored and 0.4 per cent foreign born. A birth rate of 15.5, a crude death rate of 11.2, a tuberculosis death rate of 3.4 (per 100,000) and an infant mortality rate of 46.1 were recorded. Of 19 infant deaths, 14 occurred during the first month. One nurse is employed by the Board of Health, and one by the state and federal government, but their work is arranged on a generalized basis, with a nurse employed jointly by one of the local boards of education and boards of health acting as supervisor. The health officer is secretary-treasurer of the county public health league, and also of the county medical society, and is medical director of school work in Troy. There are other indications in the report of interesting coöperative enterprises. Forty-nine per cent of the school children are protected from diphtheria. A gross per capita expenditure of 39 cents for the year is reported by the department.

Victoria, Australia—A new code of duties of medical officers of health has been issued by the Commission on Public Health. Furthermore, the Health Act

1919, requires the appointment of qualified inspectors by councils, but allows the retention of long-service inspectors. At present, the 1927 report states, 81 councils employ inspectors qualified by examination, and 82 employ inspectors qualified by 5 years' service before the passing of the Act, while 31 were granted exemption. The combination of neighboring municipalities in making joint appointments of full-time inspectors is encouraged. It is also interesting to observe from this report that diphtheria immunization, particularly of school children, is gradually being undertaken in different districts.

Manchester, N. H.—The Health Officer of Manchester is also superintendent of the isolation hospital. The city of 82,500 population in 1927 expended 96 cents per capita, including 33 cents per capita for the hospital. The staff organization is shown in the first 2 pages of the report, and this is followed by a 1-page statistical summary for the last 2 years. The lowest general death rate ever recorded for the city is that of 1927—10.55. A birth rate of 20, an infant mortality rate of 71, a tuberculosis death rate of 56 (per 100,000), and a diphtheria death rate of 2.4 are noteworthy.

Diphtheria prevention work started in November, 1921. During that year, 469 cases and 31 deaths were recorded, as compared with 9 cases and 2 deaths in 1927. A prenatal and preschool child service is being developed by the district nursing association in coöperation with the local medical association and the health department. Births are analyzed in the report by months, wards, nativity, and infant deaths are classified by ages, months, and cause. Of 108 infant deaths during the year, 76 occurred in the first month of life, 72 being classed as due to congenital or early infancy causes. By legislative enactment, on and

after June 1, 1928, all milk sold in restaurants, lunch rooms, or on stands must be dispensed in the original package. The report contains several interesting statistical tables with descriptive text.

Cincinnati Dental Survey—As a result of the formation in 1922 of the Mouth Hygiene Council of the Cincinnati Public Health Federation, there has recently been completed and published a survey report of community dental facilities. The purpose of the council is stated to be to coordinate the work of the organizations in the city, which are doing any phase of mouth hygiene work; to eliminate any duplication that may exist, and to formulate plans for meeting needs which now exist or which may arise and which are not adequately met.

In Cincinnati in 1925, with a population of 408,559, there were 396 dentists (1 to 1,107 persons) and 901 physicians (1 to 453 persons). The ratio of dentists to population in the United States is 1 to every 1,882 persons. All general hospitals in the city render service in oral surgery and extraction. Prophylaxis, treatment, X-ray, laboratory, referred cases and observation seem to be services common to most of them. All children entering Children's Hospital on general service and all clinic patients including 2 years of age, are given routine dental examinations. The dental department is combined with the surgical, so that extraction and surgical procedures may be carried out in one of the operating rooms. Interesting data are submitted for both general and special institutions.

The Public Dental Service Society, in cooperation with the Board of Education, serves pupils in public schools. Certain health centers and dispensaries maintain completed services, while the dental clinic of the Babies' Milk Fund Association, for example, is limited to the care of expectant mothers and children of preschool age. As in many other cities, the facilities for adults are limited, although a few organizations and health centers are attempting to meet this situation. The scope of these activities and the organization of services are detailed in this interesting report of 52 pages.

Among the suggestions for a community dental program, it is recommended that the excellent opportunity for educational and dental inspection work in connection with the summer round-up of preschool children, be utilized. It is further stated that the entire service of dental examinations, dental prophylaxis and curative work for school children who cannot afford to pay, should ultimately be conducted by the Board of Health entirely at public expense, and that this should include adequate supervision. It is felt that education in dental hygiene among school children will be most effective if incorporated in a general scheme of health education and training in health habits. The Board of Health has established in its health center a chair for corrective dental work for adults—at present limited to patients registered in the tuberculosis and venereal disease clinics. It is recommended that this service shall be made available for other patients. "Further provision for adult dental service should be provided by the outpatient department, especially to provide for indigent cases referred by family service agents."

NEWS FROM THE FIELD

DR. FRANCIS HONORED

EDWARD Francis, M.D., of the U. S. Public Health Service, was presented with a gold medal by the American Medical Association at its annual meeting held in Minneapolis, Minn., in June, for his research work on tularemia. The committee on awards in making the presentation considered the results obtained by Dr. Francis the most important medical work of the year. Dr. Francis is recognized as the outstanding authority on this disease in the United States. While studying his first case of the disease in Utah, Dr. Francis fell a victim to tularemia and has since devoted his time to the prevention and cure of the disease.

Tularemia was discovered in a ground squirrel in Tulare County, Calif., in 1910 by Dr. G. W. McCoy of the U. S. Public Health Service.

MICHIGAN PUBLIC HEALTH ASSOCIATION

THE Michigan Public Health Association held its midsummer meeting July 14 at the University of Michigan, Ann Arbor, Mich. Members attended the Public Health Institute which was in session that day. County and district health units were the principal subjects discussed under the leadership of Senior Surgeon L. L. Lumsden of the U. S. Public Health Service, and Guy L. Kiefer, M.D., Commissioner of Health, State of Michigan. Other sessions were devoted to "Our Present Knowledge of Cancer," by A. S. Warthen, M.D.; "Tularemia," Walter M. Simpson, M.D.; "Typhoid Fever," L. L. Lumsden, M.D.; "Rabies," Haven Emerson, M.D.; and "Health Economics," Nathan Sinai, M.D. Assistant director of the National Committee on the Cost of Medical Care. John Sundwall, M.D., president of

Michigan Public Health Association chose as the subject of his presidential address, "The Physician and the Layman in Public Health Work."

CANADIAN FARMERS' HEALTH PROTECTED

DOCTORS and hospital facilities are brought to the door of the Canadian farmer living in the western prairie provinces, by the traveling clinics that have been instituted to serve the isolated rural districts. Each clinic in this rural medical service includes 3 nurses, 2 doctors and a dentist. In the case of a tonsillectomy and the removal of adenoids, one doctor performs the operation while the other doctor remains behind for 24 hours after the clinic has moved on to supervise the convalescence of the patients.

During 1927 the provinces reported the following births per 1,000 population: Manitoba, 22.9; Saskatchewan, 25.0; Alberta, 23.8; British Columbia, 17.4. The corresponding deaths for these provinces respectively were: 8.3; 7.4; 8.5, and 9.6. This report was made by the Department of Colonization and Development of the Canadian Pacific Railway.

INCREASE OF CANADIAN FULL-TIME HEALTH UNITS

FULL-TIME health units established in the provinces of Canada are rapidly increasing. The greatest development of this medical service has been in the Province of Quebec, and before the year closes it is contemplated that at least 20 more units will be established. British Columbia and Saskatchewan also have several full-time health units.

A unit consists of a full-time health officer who has had training in public health administration; one or more public health nurses; a sanitary inspector

and a clerk. Such a staff cares for the health of a county of about 40,000 population. The total cost of operating a unit, including traveling expenses is from \$10,000 to \$12,000 a year.

The Pictou County Medical Society, Nova Scotia, recently appointed a committee to investigate the establishment of a full-time health unit in Pictou County.

INDUSTRIAL SANITATION AT HARVARD

A NEW course of study in the Harvard Engineering School in coöperation with the Harvard School of Public Health will be inaugurated at the opening of the college year. Directors of these schools have become convinced that there is a need for engineers whose special studies have prepared them to cooperate with the industrial physician in problems of plant sanitation and hygiene. This course to be known as "Industrial Sanitation," will lead to the degree of Master of Science in Engineering.

HEALTH—SUBJECT AT CALIFORNIA MUNICIPAL INSTITUTE

PUBLIC health was one of the subjects discussed at the Institute of Municipal Administration at the University of Southern California, Los Angeles, Calif., August 13-18. This was the first educational project of its kind for municipal directors. The institute brought together mayors, city managers and commissioners, city and county officials and citizens actively interested in public affairs. The 6-day program covered a scientific and practical study of modern municipal administration.

Abel Wolman, chief engineer of the State Department of Health, Baltimore, Md., a member of the Engineering Section of the American Public Health Association, headed the section on sanitary engineering. Professor Ira V. Hiscock of the School of Public Health, College of Medicine, Yale University, also a

member of the American Public Health Association, and who was in Los Angeles County making an appraisal of health activities of the county, under direction of the Committee on Administrative Practice, American Public Health Association, was a special lecturer on public health at the Institute.

SEDGWICK MEMORIAL LECTURE AT WOODS HOLE

THE seventh William Thompson Sedgwick Memorial lecture was given by Edwin Grant Conklin, Ph.D., Sc.D., LL.D., at the Marine Biological Laboratory, Woods Hole, Mass., July 27. Dr. Conklin's subject was "Problems of Development." He is a member of the National Academy of Sciences and Professor of Biology, Princeton University.

This lectureship was established in 1922. The lectures are under the auspices of the Department of Biology, Massachusetts Institute of Technology, which was created by Professor Sedgwick. The previous lecturers have been, Edmund Beecher Wilson, Ph.D., M.D., William Henry Welch, M.D., Winthrop John Vanleuven Osterhout, Ph.D., Sc.D., Charles Value Chapin, M.D., Sc.D., Thomas Hunt Morgan, Ph.D., S.C., and Haven Emerson, M.D.

HEALTH TO BE TAUGHT BY MOTION PICTURES

A series of health education films for use in classrooms of public schools will be worked out by the Department of Biology and Public Health, Massachusetts Institute of Technology, and the Eastman Teaching Films, Inc. Professor C. E. Turner of M. I. T. will direct the preparation of the subject matter to be filmed, and he will be assisted by Georgie B. Collins, who has resigned as director of health education in the public schools of Malden, Mass., to begin work on the films.

BETTER HEALTH IN MISSISSIPPI FLOOD AREA

DEVELOPMENT of sanitation following the Mississippi Valley flood has steadily extended throughout the flood area until 78 counties are listed as receiving adequate public health protection from a staff of more than 300 full-time health workers. The U. S. Public Health Service reports that better communities are being built on the ruins of those destroyed by the flood, and that a modern and more extensive health program has been inaugurated.

RADIUM-MESOTHORIUM DANGEROUS

THE Committee on Public Health Relations of the New York Academy of Medicine is protesting the extent of the use of radium-mesothorium in industry because of its danger to workers. The committee has sent a protest to Surgeon General Hugh S. Cumming of the U. S. Public Health Service in the hope that he will investigate conditions.

MANY CALIFORNIA WATER SUPPLIES ARE NOW CHLORINATED

A recent survey of public water supplies in California reveals the fact that the water from 68 such supplies is

chlorinated, thereby insuring the safety of the drinking water used by 3,185,000 regular consumers. The total amount of water so treated is one-half billion gallons daily. This constitutes an outstanding achievement and is largely responsible for the great reduction in water-borne typhoid in California. The development of this procedure has been comparatively rapid, since chlorination was started in California only 13 years ago.

ENGINEERS GO TO JAPAN

THE first World Engineering Congress will be held in Tokio, Japan, October, 1929, under the auspices of the Kogak-kai, the Engineering Society of Japan. The purpose of the congress, first proposed by the Kogakkai, which is making elaborate preparations for the international meeting of engineering societies, is to promote international coöperation in the study and application of engineering science and permit the exchange of professional ideas.

The American committee with headquarters at the Engineering Societies Building, New York, N. Y., is planning the program to be contributed by American delegates from national engineering societies.

PERSONALS

DR. J. L. PARKER has been appointed City Health Officer of Brawley, Calif., to succeed Dr. Eugene Le Baron, who has served that city for many years.

DR. CLARA M. RINEHART has been appointed City Health Officer of Tehachapi, Calif., to succeed Dr. Rupert G. Doupe.

CLARENCE R. WALTER has succeeded Dr. M. E. Westphal as City Health Officer of Atherton in San Mateo County, Calif.

DR. JOHN W. COX of Alexandria, Va., has been appointed a field representa-

tive of the American Society for the Control of Cancer, New York, N. Y.

DR. GEORGE H. PRESTON, Baltimore, Md., has been appointed Commissioner of Mental Hygiene by Governor Ritchie to succeed the late Dr. Arthur P. Herring.

DR. PHILETUS A. HAYES, for more than 32 years Health Officer of Afton, Chenango County, N. Y., resigned on July 1.

DR. FRED J. WAMPLER has been appointed Professor of Preventive Medicine in the Medical College, University of

Virginia, and Medical Director of the out-patient department. He will also have charge of the laboratory of clinical pathology. Dr. Wampler was formerly field associate director for Shansi Province, China, for the Council on Health Education. At one time he served as acting director of the council.

DR. JOHN A. GARDNER has resigned after many years' service as Health Officer of La Grange Park, Ill.

SURGEON GENERAL HUGH S. CUMMING has been elected a corresponding member of the Royal Society of Medicine of Great Britain.

EDNA L. FOLEY, Superintendent, Visiting Nurse Association of Chicago, has been awarded the honorary degree of Doctor of Science by Smith College, in recognition of her work in the field of public nursing. Smith College has awarded this degree to only a few others, among whom are Madam Curie and Dr. Alice Hamilton.

DR. SAIR C. MOORE has been appointed Health Officer of Cadillac, Mich.

DR. PAUL D. MOSSMAN, trachoma specialist of the U. S. Public Health Service, recently made a tour at the request of the Montana State Board of Health to ascertain in which sections of the state trachoma exists. The schools of Wolf Point and Cut Bank, Mont. were particularly examined, as there seemed to be a confusion of opinion in the diagnosis of cases in these schools.

DR. EDWARD P. WHITE, Columbia, S. C., has been appointed Director of the Cherokee County Health Department, succeeding Dr. Patrick H. Smith of Gaffney, S. C.

DR. WALTER G. DARLING has been appointed Health Officer of Shorewood, Wis., to succeed Dr. H. H. Becker.

DR. ROLAND E. SCHOEN has been appointed Health Officer of Beaver Dam, Wis.

DR. JAMES D. LEWIS has resigned as Director of Public Health of Scranton, Pa.

DR. WILLIAM L. HELMS has been appointed Health Officer of Taylor, Tex.

DR. MARY BERKES WETMORE, the first woman graduate from the School of Medicine, University of Buffalo, died June 18 in Buffalo. She was the widow of Dr. Samuel W. Wetmore a physician of Buffalo a member of the faculty of the Buffalo University School of Medicine.

DR. J. F. HAZZLEWOOD, director of the Toronto Public Health Laboratory, Toronto, Can., has resigned to fill the vacancy of the Medical Staff of the Ontario Workmen's Compensation Board caused by the death of Dr. W. E. Struthers.

DR. S. B. RICHARDS has been appointed health officer of San Bernardino County, Calif., to succeed Dr. Emil W. Meyer.

DR. JOHN B. CRAIG has been appointed Health Officer of the City of Upland, Calif.

DR. SIDNEY A. GOYETTE, Yuba City, Calif., has succeeded Dr. Trusten P. Peery as Health Officer of Sutter County.

DR. ARNOLD S. ANDERSON, who was formerly with the sanatorium is now in charge of the tuberculosis division of the Minnesota Public Health Association, St. Paul, Minn.

DR. JAMES S. FITZHUGH, Island, Ky., has resigned as Health Officer of McLean County.

DR. HARRIS W. TERRELL has been appointed full-time Health Officer of Ohio County, Ky.

DR. ALEXANDER A. WEECH, Baltimore, Md., is to spend a year in Peking Union Medical College, Peking, China, as associate professor of pediatrics.

DR. CLARENCE W. BUCKMASTER has been reappointed health officer of Yonkers, N. Y.

ADRENALIN

[The Parke, Davis & Co. Brand of Epinephrin, U. S. P.]

IT IS not alone by restoring heart action in cases of apparent death from shock that Adrenalin has earned its reputation as a life-saver. In cases of collapse when the heart fails because of ebbing stimulus, Adrenalin supplies that stimulus by its direct cardiac action and by increasing the blood-sugar—glycogenolysis. And in many a less extreme case (of asthma for example) Adrenalin has rendered the patient's life endurable and prolonged it for years.

It is in daily demand for the reduction of inflammatory conditions of the mucosa—in eye, nose, throat and genito-urinary practice; also for its styptic effect in hemorrhagic conditions, and as an aid to the economical and satisfactory use of local anesthetics.

Adrenalin was made available to the medical profession by Parke, Davis & Co. in 1901 as a result of researches begun in our laboratories in 1900, and was the first hormone ever isolated from an animal organ.

Literature will be supplied to physicians on request.

PARKE, DAVIS & CO.

DETROIT, MICHIGAN

ADRENALIN (EPINEPHRIN, P. D. & CO.) IS INCLUDED IN N. N. R. BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION

There is no substitute

FOR

Ease and Comfort

IN THE MIND OF

The Suffering Patient.

CAPROKOL GIVES RELIEF, ALMOST IMMEDIATELY, FROM THE DISTRESSING SYMPTOMS OF INFECTIONS OF THE URINARY TRACT.

CAPROKOL TREATMENT INSURES:—

Hours of continuous rest (unbroken by the necessity for frequent urination); subsidence of fever; increased appetite; marked improvement in general health and, in most cases, complete disinfection of the urinary tract.

Capsules for adults.

Solution for Children.

Malden Studies on Health Education and Growth

C. E. TURNER, DR.P.H., FELLOW A. P. H. A.

*Professor of Biology and Public Health, Massachusetts Institute of
Technology, Cambridge, Mass.*

IN 1925, the writer made a preliminary report upon a series of health education studies which were undertaken in the city of Malden, Mass., in the fall of 1921 to answer the following questions:

Is health education practicable?

Can the child's habits be changed through health education in school?

What are the best methods in health education?

Does health education have a measurable effect upon growth?

The preliminary report¹ gave clear-cut evidence of the practicability of health training in schools, and presented specific data showing improvement in several health practices. The results of the study looking toward the development of ideal methods are to be found in the books of the Malden Health Series.² Brief reports upon special phases of the studies have been made in the *Journal of the National Education Association*.³ The present report deals only with the last of the four questions.

SELECTION OF GROUPS AND THE COLLECTION OF DATA

The preliminary report describes the procedures used in placing one group of children under an organized health education program and in collecting health and growth data from this group and a similar control group of children. The present paper reports upon the significance of growth data. The sanitarian, educator, or statistician will ask two questions at the outset:

Were the experimental and control groups of children fair and comparable samples of the school population?

Were the records collected with accuracy and uniformity?

As shown in the earlier report, the children selected for the study

For purposes of this study the children were separated into groups on the basis of their relationship to normal weight. Groups 1 and 5 include children more than 10 per cent underweight; groups 2 and 6 include children from 90 per cent to 100 per cent of average weight; groups 3 and 7 include children from 100 per cent to 120 per cent of average weight; and groups 4 and 8 include children more than 120 per cent of average weight.

included all children in the 4th, 5th, and 6th grades in the Faulkner and West Schools. The children in the control group consisted of all of the pupils in the same grades at 3 other selected schools. The two groups of children represented the same racial types of similar economic status. The conditions of living of the two groups were not changed except for the health education program given to the children in the experimental group.

Perhaps the best comparative biological data for the two groups will be found from a study of their growth status at the beginning of the experiment (see Table I). Data for boys and for girls are given separately because of their different growth rates. It will be seen that the average age, height, weight, and relationship to normal indicate that the two groups of boys were almost exactly comparable. A similar indication will be seen from a study of Chart I. A similar study for the two groups of girls will show that the girls in the control group were biologically superior to those in the experimental group since, although they were younger, they were taller, heavier, and there were fewer underweight.

These figures show that up to the time the experiment began the growth of the two groups of boys had been practically the same and

* Based upon Wood Tables.

† Based upon Baldwin Averages.

that any superiority in growth which did exist was in favor of those in the control group. They show that the girls in the experimental group had grown distinctly less rapidly than the girls in the control group up to that time. These figures give us further assurance concerning the comparability of the two groups, supplementing as they do our care in selecting them.

The children were weighed at the same time each day and with the lightest indoor clothing.* Such individual variations as would naturally exist in the weight of clothing or ingested food would balance in group averages. Periodically the scales were tested for accuracy. Weights were taken to the nearest quarter pound. The children in

* Georgie B. Collins collected all of the data from the experimental group, and trained the nurse who assisted in the collection of data from children in the control group.

the experimental group were weighed monthly, and those in the control group three times a year.

Height was taken for both groups three times each year. Both height and weight were taken with shoes on. Because of the unpopularity of the removal of shoes, the children were permitted to keep them on, as individual variations were counterbalanced in averages.

In addition to collecting height and weight data, computations were made to show the relationship of each child to average or normal weight. No attempt was made to determine the relative importance of the various habits in which improvement was demonstrated. We were seeking to determine whether the combined effects of health training through the classroom were sufficient to produce differences in the growth rate which were significant and which could not possibly be due to *accidental* variations in the rate of growth of individuals in the two groups studied.

INCREASE IN WEIGHT

The boys with the health education program showed an average gain for the 20 months of the experiment amounting to 13.52 pounds while the boys in the group which did not have the health education had a gain for the corresponding period of 11.13 pounds. The former group gained 18.4 per cent of its original weight, the latter 15.1 per cent of its original weight. The gain in weight of the boys having the health education program exceeded the gain of the boys without health training by 21 per cent.

Table I shows that such slight differences as existed in height, weight, and the percentage of the group seriously underweight, were in favor of the boys in the control group. One notices, however, that the average age of the boys in the experimental group was 0.3 year greater than that for the control group. The expected gain at different ages varies, and one naturally asks whether this difference in the rate of gain may not have been due to an accidental age distribution because of which there were more boys in the experimental group at ages of maximum gain.

In order to determine whether the greater gain in weight may have been due to the age distribution of the group we determined the expected gain on the basis of age alone. Studies of the gains of many thousands of children at different ages have made it possible to prepare tables showing the average or expected gain for boys and for girls at each age level. Such data are given by Baldwin¹ in terms of expected or average gain in ounces per month. By determining the number of boys at each age level for each of the two years of the

study; multiplying the number of boys at each age by the expected gain for that age and adding the product; we get the total expected gain on the basis of age alone for each group. From this we find the expected gain for boys in the experimental group to be 12.7 pounds (on the basis of age alone) and for the boys in the control group 12.4 pounds. Clearly the difference in rate of gain was not due to age distribution. This is further emphasized by the fact that up to the time the study began the boys in the control group had been growing slightly faster than the boys in the health education group.

There remains to be considered the statistical analysis of the data with a consideration of the limits of error. Such a study will tell us whether these differences in average growth are *accidental* differences, due to a statistical population of scattered variants which are overlapping, or whether the differences are so great as to make it certain that they are *real*.

Chart II shows the distribution of gains in weight by classes for the 20-month period in question. This distribution, like the one shown above, keeps the division of children according to the four weight groups into which they fall. Let us compare the two populations, applying the following commonly used formulae.

$$\sigma = \sqrt{\frac{\sum D^2 f}{n}}$$

$$\text{P. E. Av.} = \pm 0.6745 \frac{\sigma}{\sqrt{n}}$$

$$\text{P. E. diff.} = \sqrt{(\text{P. E. Av.}_1)^2 + (\text{P. E. Av.}_2)^2}$$

Completing these computations, we find group 1 (Health Education) to have a mean of 13.58, with a probable error of ± 0.40 . Group 2 (Control) has an average of 11.08, with a probable error of ± 0.463 . The probable error of the difference $\sqrt{0.40^2 + 0.463^2}$ is ± 0.612 .

$$\frac{\text{Diff.}}{\text{P. E. diff.}} = 4.09.$$

We see that the actual difference between these averages is more than four times the probable error of the difference. We have then a measure of the reliability of this difference. If the difference divided by the probable error of the difference were zero, there would be an even chance or fifty chances in one hundred that the true difference was greater than zero. Under such a condition it would be expected that in a long series of trials half of the experiments would show a superior growth in one group and half in the other. Similarly we find that when the difference is four times the probable error of the difference the "chances in one hundred" are 99.7 that the true difference under the contrasted conditions is greater than zero. In other words,

CHART II

DISTRIBUTION OF GAINS IN WEIGHT BY 3.25 LB. CLASSES—OCT. 1921-JUNE 1923

	2.50	5.75	9.00	12.25	15.50	18.75	22.00	25.25	28.50	31.75	35.00	38.25

EXPERIMENTAL BOYS GROUP 2		4	28	13	5	5	4	1	7			
NO 132 GROUP 3		6	6	6	4	1	3	1	1	1		
GROUP 4		1			1	1						1
GROUP 5	1	4	10	10	10	8	1					
EXPERIMENTAL GIRLS GROUP 6	1	2	10	8	11	12	6	5	3			
NO 141 GROUP 7	1	2	7	4	4	7	4	3	1			
GROUP 8				2	1	1			1			1

	24.25	175	5.00	8.25	11.50	14.75	18.00	21.25	24.50	27.75	31.00	34.25	37.50	39.25
GROUP 1	1		7	10	3	2	3		1					
CONTROL BOYS GROUP 2			13	17	15	4	3	1	1	1	1			
NO 107 GROUP 3				8	8	2		1			1		1	
GROUP 4	1					1			2				1	
GROUP 5			3	1	7	6	6	3						
CONTROL GIRLS GROUP 6		4	2	6	10	10	5	4	1	2	1			1
NO 95 GROUP 7		1	1	3	2	1	2		1	3				1
GROUP 8			1	1		2	1		1		1			1

in this case the actual difference is enough greater than the probable error to indicate complete reliability.

It may be noted that one boy in the control group actually lost weight instead of gaining over the period of this experiment. This was not because of illness. Because the case was unusual, however, it was desired to see whether it would affect the general results. Consequently that case was dropped from the list, and complete computations were made once more for the 106 boys remaining in the control group. These computations showed an actual difference of 3.8 times the probable error of the difference, or 99.5 chances in one hundred that a real difference exists.

Comparison of the figures in Table I will show that the data for the *underweight* boys considered separately are essentially similar to the data for the group as a whole.

The comparison between the weight increases of the two groups of girls is no less significant but very different in nature. The two groups of boys were alike, but the boys with health education made an appreciably better gain. In the case of the girls those having health education, although smaller and biologically inferior, gained slightly more in weight than did the larger and superior girls in the control group.

The girls in the control group were slightly nearer to normal weight than the girls in the experimental group. They averaged 0.6 inch taller, and 2½ pounds heavier. Thus, although they were a trifle younger and would have been expected to be slightly smaller, they

were in reality appreciably taller and heavier and slightly nearer to normal weight. Their growth rate in both height and weight had, therefore, been more rapid than that of the girls in the experimental group up to the time this experiment began.

The average gain in weight for girls in the experimental group was 15.31 pounds for the 20-month period; and for the girls in the control group the average gain was 15.10 pounds. The difference between these gains is not appreciable. The significant fact is that the smaller girls in the health education group gained as much as the larger girls in the control group.

The computation of expected gain on the basis of age alone (experimental 16.29 pounds; control 16.10 pounds) shows a similar expected gain for the two groups on the basis of age distribution. We find that the girls in the health education group gained 20.7 per cent of their original weight and the girls in the control group gained 19.8 per cent of their original weight.

As will be seen by reference to Table I, the comparative results from the underweight girls *only* are similar to those from the group as a whole.

GROWTH IN HEIGHT

Because of an unfortunate error which was not noted until too late, data for height failed to be taken for one section of the control group during the second school year of the study. We are able, however, (1) to compare the growth in height for the two groups during the *first* year, and (2) to compare the growth in height for the health education children for the 20-month period with the expected standards.

Comparing the growth of both boys and girls in the experimental and control groups for the period October, 1921, to June, 1922, we find that the children in the health education group gained 1.375 inches and the children in the control group 1.062 inches. Computing the expected gain on the basis of age, according to the plan outlined above we find that the expected gain for the children in the experimental group was 1.37 inches and for the children in the control group 1.39 inches. Actually the children having health education gained in height 28 per cent more than the children who did not have health education. Statistical computations for the two groups, like those indicated in the above section on weight, show that the actual difference in average gain between the two groups was 8.8 times the probable error of the difference

$$\frac{\text{Diff.}}{\text{P. E. Diff.}} = 8.8.$$

Comparing the growth in height for the children in the health education group over the 20-month period with the expected gain on the basis of age, we find that the actual gain was 2.25 inches and the expected gain was 2.05 inches. The actual gain was, therefore, 9 per cent greater than the expected gain.

The comparable increase in growth rate in both height and weight shown by the health education group is further borne out by the following data on the relationship of these two groups to normal weight.

RELATION TO "NORMAL" OR AVERAGE WEIGHT

We have heard much about underweight among school children, and many public school systems have come to use extensively the figure of percentage normal weight. This figure is the actual weight of the child expressed as a percentage of the average weight for chil-

GRAPH I

dren of its height, age, and sex. From the literature on child health one might naturally look for the success of a school health-training program to be measured by a reduction in the number of underweight children or an approach of the average normal weight toward 100 per cent. Our figures do not show such a change. They indicate an increase in the rate of growth in both height and weight, but not a fundamental change of body proportions.

Present space does not allow a consideration of the problem of malnutrition, underweight, and the regular program of weighing and measuring. It is understood that underweight and malnutrition are not synonymous terms, and that often difficulties arise when they are used as such. Lest, however, the following data should imply the conclusion that the weighing and measuring of school children should be done away with, we wish to state that the Malden studies have confirmed our belief that the process of interesting a child in his growth, through regular weighing, is the most valuable single procedure in motivating him toward the adoption of health habits. This is an educational not a clinical process. Underweight figures are useful clinically when properly interpreted and applied. Consistency of growth is also an important and valuable index. Failure to increase in weight during a single month is not significant, but loss of weight or failure to gain over a period of three or more months should cause the teacher to call the attention of the physician or nurse to the child to see whether he needs special attention.

Several of the children studied came out of the underweight group. Many individual charts like that of Lois T., shown herewith, could be produced. Many other children had charts like that of Eleanor H., showing an increase in weight in excess of that expected at the age level, and an unexpectedly rapid increase in height which still left the child underweight. Eleanor was a slender type child who grew rapidly but maintained the same bodily proportions. At the same time, other children fell into the underweight group from higher levels of "per cent normal weight."

Each child's "normal" weight, or percentage of average weight, was computed in October, March, and June of the first year, and at similar dates for the second year, in the case of the experimental group. The absence of height data for part of the control group during the second year made impossible the computation of average weight percentages.

One of the first things to note is a seasonal variation in underweight. In June, 1922, 9 of the children who were in the 10 per cent underweight group the preceding October, had come out of that group,

GRAPH II

but 17 children who were not 10 per cent underweight in October had dropped into the 10 per cent underweight group. Similarly in the control group, 11 children came out of the underweight group during the school year, but 19 children dropped into the underweight group. In both the experimental and control groups we find, therefore, 8 more children in the 10 per cent underweight group in June than in October.

Table II shows the average percentage normal of groups 1 to 8 in both experimental and control children during the school year 1921-1922. While these changes are not consistent it will be noted that the average per cent normal is lower in June than in October, and we shall see later that this seasonal fluctuation is greater than the fluctuation from one year to another.

TABLE II
AVERAGE PER CENT NORMALS—1921-22
Boys

Group Number and Number of Children in Group		October		March		June	
Expt.	Contr.	Expt.	Contr.	Expt.	Contr.	Expt.	Contr.
33	(1) 25	86.72	86.51	87.86	87.43	86.40	86.71
67	(2) 56	95.01	94.83	95.81	94.79	94.17	93.25

4	(4) 4	123.65	128.55	125.55	129.55	124.10	126.97
GIRLS							
44	(5) 26	85.38	84.50	86.12	85.58	84.37	85.00
58	(6) 46	94.66	95.18	94.53	95.46	92.88	94.29
33	(7) 15	107.93	105.00	108.75	105.10	107.57	105.17
6	(8) 8	136.00	134.41	133.31	132.48	132.75	130.81

In October, 1922, 17 of the 77 underweight health education children were out of the 10 per cent underweight group, but 5 who were not in the group at the beginning had dropped back into it. Comparing one October with the next, then, we have a reduction of the number of 10 per cent underweight children from 77 to 65. This is not significant, however, for, by reference to individual records, it is seen that several of the children who have gone out of the 10 per cent underweight group have not gone very far above the 90 per cent figure. Comparing one June with the next we find 85 children in the underweight group in 1922, and 88 children in the underweight group in 1923.

A study of individual children shows a continuous plus and minus variation in the child's relationship to normal at succeeding weighing

and measuring periods, due to the roughness of the measure and the inexactness of the method of determining this figure; but our data do not present significant evidence of a reduction in the number of underweight children. A similar situation is found when we deal with small groups like an individual class of boys or girls. When we combine the "per cent normal" figures for a large number of children who are individually varying in both plus and minus directions from time to time, the average tends to remain constant.

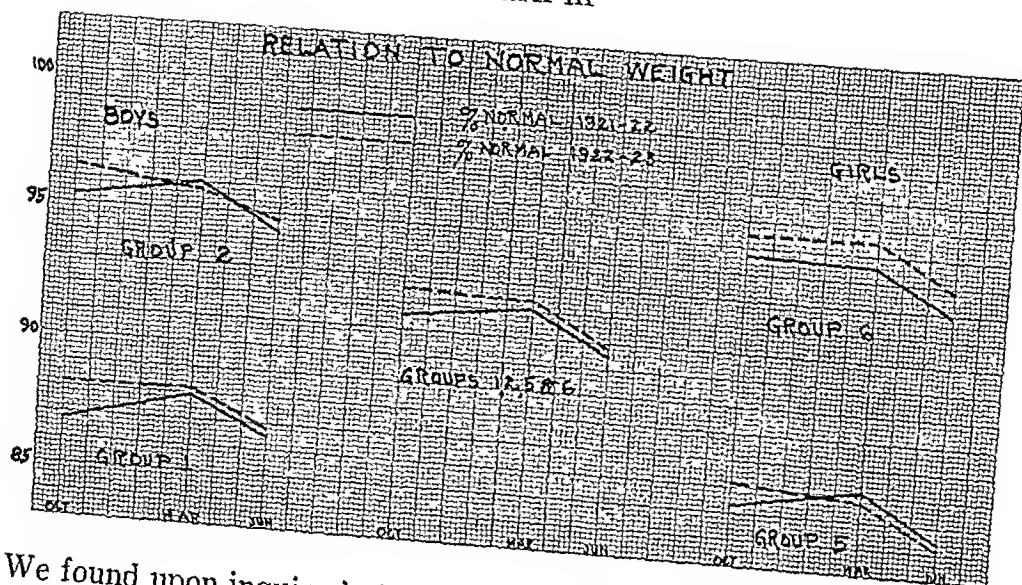

Table II does not show a significant change in the percentage of underweight when experimental group children are compared with control group children. In Graph III for Health Education Children, shown herewith, group 1 (boys more than 10 per cent underweight), group 2 (boys from 1 to 10 per cent underweight), group 5 (girls more than 10 per cent underweight), and group 6 (girls from 1 to 10 per cent underweight) are compared during the two years of the study. The averages for *all* underweight health education children were combined in the curves shown at the center of the graph. It will be seen that this group of children who were underweight in October, 1921, were slightly nearer normal during the school year 1922-1923 than during the school year 1921-1922. The seasonal variation, however, is greater than the difference between the two years.

When we make a statistical analysis of the figures, moreover, we find that they are not significant. The statistical analysis of the figures for March, 1923, and for March, 1922, shows the average percentage normal for 202 children in the control group in March, 1923, to be 92.222, while the average for the same children in March, 1922, was 92.037. The difference of these averages is 0.18. The probable error of the average for 1923 is ± 0.31 and the probable error for the 1922 average is ± 0.26 . The probable error of the difference is ± 0.404 while the difference itself is only 0.18. No significance statistically, therefore, can be attached to this finding.

By comparing the averages for the two October computations we find their difference to be 1.08 and similar data for the two June studies show the difference to be 0.36. Since the average per cent normal figures remain essentially the same, the probable error of the difference between these last mentioned figures would not be greatly different from that computed (± 0.404). We see, therefore, that, although the underweight children having a health education program average slightly nearer normal weight during the second year than during the first year, the difference is not great enough to be significant when the usual statistical measurements are applied.

The whole picture needs to be kept in mind in this connection.

GRAPH III

We found upon inquiry in February, 1925, that 23 of the 77 children who were 10 per cent underweight at the beginning of the study were left in our schools. The rest had moved away. Of these 23 children, 10 were still in the 10 per cent underweight group (9 girls and 1 boy). Figures like these when quoted by themselves make it seem that the health program may greatly reduce the number of underweight children. When, however, one looks at the wide fluctuations in percentage normal for individual children over succeeding years, when one sees that the size of the group stays about the same, when he contemplates the lack of precision in computing the percentage normal figure in the first place, and when he applies actual statistical methods to such figures as those we have obtained, he cannot conclude that health education will do away with the group of underweight children.

Specific studies have been made upon the significance and limitations of the underweight figure as applied to the individual child and as applied to the group. Space does not permit reporting them here.

SUMMARY AND CONCLUSIONS

Growth records were carefully and accurately taken over a period of 20 months from 273 children under the influence of a reasonably intensive health education program and from 202 children in a comparable control group who continued in the usual school program without any special training in health beyond that previously given. The health education program proved to be a sound, practicable and acceptable public school procedure. Definite improvement in health habits was shown.

The rate of gain in both height and weight for the children receiving health education was measurably and significantly greater than for the children in the control group.

Individual children came out of the underweight group. Seasonal fluctuation in the amount and extent of underweight was shown. Significant and statistically measurable changes in the underweight status of the group as a whole were not shown.

More healthful habits of living, resulting from the health education program, produced an improved rate of growth, but not a fundamental change in the height-weight ratio.

Public Health Training in Great Britain

IN a recent issue of the *Medical Officer* the history of public health training by universities and medical schools of the British Isles is given. The University of Edinburgh was the first medical school in Great Britain to institute a degree of public health, and the first graduation of sanitarians was in 1875. That same year the University of Cambridge established the conditions for the award of a diploma in public health. As early as 1874 the Senate of the University of London passed a resolution that a certificate in public health should be awarded, and in October, 1888, it resolved that a degree of M.D. in State Medicine should be instituted. The Royal College of Physicians, London, first granted a certificate in hygiene in 1885 and two years later this was changed to a diploma, granted jointly by the Royal College of Physicians and the Royal College of Surgeons of England. The University of Aberdeen conferred its first diploma in public health in 1887 and the joint faculties of the Royal College of Surgeons and Physicians of Glasgow in 1890. Oxford University conferred its first public health diploma in 1898. The University of Glasgow instituted the degrees of B.Sc. and D.Sc. in public health in 1903, but it was not until 1905 that the B.Sc. degree was granted and the first D.Sc. degree in 1912.

The graduate in medicine from the University of Edinburgh has to specialize more or less for a period of two years before he can enter for the final B.Sc. degree and a period of five years must elapse before he enters for the D.Sc. degree in public health.

During recent years many women graduates from medical colleges have entered the public health service.

A Fallacy in the Standard Methods of Examining Disinfectants

L. P. SHIPPEN, M.D.

Norwich Pharmacal Company, Norwich, N. Y.

THE three most commonly used tests for determining the germicidal efficiency of disinfectants are the Hygienic Laboratory,¹ the Rideal Walker,² and a modification of the Rideal Walker method,³ employed in the Regulatory Branch of the U. S. Department of Agriculture. In all these tests, a loopful of disinfectant, containing the test organism, is transferred to broth and the survival of the organism determined by noting the appearance of turbidity in 48 hours. In the Rideal Walker method, a 3 mm. loop is transferred to 5 c.c. of broth. In the others, a 4 mm. loop is transferred to 10 c.c. of broth. So, in all cases, a certain amount of disinfectant exists in the broth and, should the quantity be large enough to inhibit growth, a false reading will result.

Usually, this condition does not occur. For the loop carries over very little disinfectant. Thus, Abbott⁴ calculated that the loop used by him averaged 2,000 to the c.c. and that one loopful of a 1-1,000 dilution of corrosive sublimate made a final concentration of 1-20,000,000 when transferred to 10 c.c. of broth. Churchman⁵ stated one 2 mm. loop in 7 c.c. of broth made a dilution of 1-70,000.

And, from this data, one might conclude by means of the pi. r. square formula, that the 4 mm. loop, used in the Hygienic Laboratory and Department of Agriculture methods, should equal a dilution of about 1-25,000 and the 3 mm. loop, employed by the Rideal Walker test, should make, approximately, a 1-22,000 concentration. For practical bacteriostatic work, the two dilutions would be equivalent.

But, unfortunately, other factors modify this calculation and the caliber of the wire, the manner of making the loop and the thickness of the film of liquid will cause a very large variation. Two 4 mm. loops, fashioned by two separate individuals in this laboratory, measured, respectively, 130 and 170 to the c.c. and a conservative estimate would put the dilution, produced by adding the standard 4 mm. loop to 10 c.c. of broth, at not greater than 1-2,000. Even so, when we apply these figures to phenol in the solution of 1-60, commonly used against *M. aureus*, it is evident that the dilution of 1-120,000, obtained by adding one 4 mm. loop to 10 c.c. of broth, would be far too weak to have any effect.

However, phenol, although a reliable germicide, has little bacteriostatic power. Especially is this true when it is employed against *M. aureus*, the coccus that is employed to test the efficiency of products designed to disinfect wounds. It is possible to grow the strain which can be obtained from the Department of Agriculture in a dilution of 1-300 phenol and, in consequence, it is obvious that the phenol, supposedly acting as a control, could not inhibit the growth of *M. aureus* in the dilution mentioned.

But, in contrast to this weak bacteriostatic action, Abbott demonstrated that corrosive sublimate suppressed growth of this organism in peptone broth in 1-75,000 dilution and, when the broth was made without peptone, in a dilution of 1-200,000. Its germicidal power was comparatively weak, as it failed to kill *M. aureus* in 1-1,000 dilution in 20 minutes. And the author, uniformly, has obtained some bacteriostatic action in dilutions of over 1-100,000, using the broth specified in the method of the Department of Agriculture.

Now, these results are produced by transferring a 4 mm. loop or about 1/200 c.c. of a vigorous, 24-hour culture to broth containing bichloride. But, in the test, the culture first is diluted by adding 0.5 c.c. of culture to 5.0 c.c. of disinfectant, or a concentration of 1-10, so that only 1/2,000 of a c.c. is transferred and the organisms are no longer vigorous, since they have undergone treatment, for from 5 to 15 minutes, with bichloride. The fewer the number of organisms transferred and the greater their attenuation, the greater will be the bacteriostatic action of the bichloride and thus it may be expected to act in far higher dilutions, probably in one to several millions.

In order to overcome this source of error, a simple modification of the regular tests was performed. Four loops were transferred from each of the broth preparations to fresh tubes of this medium, the dilution of bichloride in the latter, thereby, being rendered infinitesimal.

TABLE I

Dilution of Bichloride	Time of Exposure in Minutes		
	5	10	15
1-100	0	0	0
Transfers 1-100	X	0	0
1-500	0	0	0
Transfers 1-500	X	X	X
1-1,000	X	X	0
Transfers 1-1,000	X	X	X
Dilution of Phenol			
1-60	X	X	0
Transfers 1-60	X	0	0
1-70	X	X	X
Transfers 1-70	X	X	X

With this modification, the efficiency of bichloride was determined by the Department of Agriculture method, at a temperature of 20° C., against *M. aureus* as test organism, with the result seen in Table I.

This experiment indicated that the method is misleading when used to determine the germicidal efficiency of mercuric chloride against *M. aureus*, for, when no sub-transfers were made, the substance appeared to kill the coccus in 1-1,000 dilution in 15 minutes, while, on the contrary, growth in the sub-transfers showed that the organism really survived after treatment for 15 minutes with a 1-500 solution.

At the same time, it should be noted that the phenol control failed to kill *M. aureus* in a 1-60 dilution in 10 minutes, although no turbidity arose in the sub-transfers after 5 minutes. This result we should expect in the case of a germicide having little bacteriostatic ac-

TABLE II

Dilution of Bichloride	Time of Exposure in Minutes		
	5	10	15

1-200	0	0	0
Transfers 1-200	X	X	X
1-300	0	0	0
Transfers 1-300	X	X	X
Dilution of Phenol			
1-60	0	0	0
1-70	X	X	0

tion, for, here, the smaller number of organisms in the second set of tubes would tend to make the reading higher in the first set, in which the small amount of phenol present would have no power of inhibition.

The finding in regard to bichloride was confirmed on several occasions. Five strains acted alike and survived a 1-500 dilution for 15 minutes and, finally, the Department of Agriculture strain and two others, freshly isolated from human infections, were tested against solutions, ranging from 1-100 to 1-500, with result shown in Table II.

Apparently, mercuric chloride does not always kill *M. aureus* in 1 per cent dilution in 5 minutes, nor in $\frac{1}{2}$ per cent dilution in 15 minutes, although its bacteriostatic action, which is not eliminated by the unmodified method, will make it seem to kill in very much weaker concentrations. This source of error was found to apply to other preparations, mercurial and non-mercurial, possessing great inhibitory power. Table III gives the result of a test made on a sample of gentian violet.

TABLE III

Gentian Violet Dilution	Time of Exposure in Minutes		
	5	10	15
1-10	0	0	0
Transfers 1-10	X	X	X
1-100	0	0	0
Transfers 1-100	X	X	X
1-1,000	X	X	X
Transfers 1-1,000	X	X	X
Phenol Dilution 1-60	X	0	0

Here, the unmodified method indicated that gentian violet kills *M. aureus* in at least a 1 per cent concentration, in 5 minutes, while the sub-transfers proved that the organism survived a 10 per cent solution for 15 minutes.

Conclusions—The method for testing germicides, employed in the Department of Agriculture, is not applicable to preparations with high bacteriostatic power, unless modified by the addition of sub-transfers.

There is no reason to believe that the Rideal Walker and Hygienic Laboratory methods would give more accurate results.

Mercuric chloride fails to kill *M. aureus* at 20° C. in dilutions of 1-200 to 1-300 in 15 minutes.

How Bridgeport Reduced Its Infant Mortality

CLIFTON C. TAYLOR, M.D.

*Director, Division of Child Hygiene, Department of Health,
Bridgeport, Conn.*

WHEN in 1918 the slogan "Save a hundred thousand babies" was promulgated, the City of Bridgeport, Conn., was among the first to take up the call. Looking back at an infant mortality rate of 109 for the 5 years, 1911-1915, and noting the number of deaths from gastrointestinal diseases, particularly during the summer months, the nurses of the local Visiting Nurses Association and four nurses from the Department of Health visited as many babies as possible during the summers of 1918 and 1919 in an attempt to reduce the number of infant deaths from that cause.

To be sure, this was a sporadic effort, but during the 3 years, 1918-1920, the work was further systematized with the opening of a milk station and summer well baby stations. The latter were well attended at first, but it soon became apparent that to make the fullest use of them it would be necessary to have a physician in attendance, as the number of visits fell off rapidly when the mothers found no doctor there to advise them. During this period the rate fell from 99.5 in 1918 to 92.1 in 1920, with a marked decrease in the deaths during the summer months.

Bridgeport is almost exclusively a manufacturing city. In 1920 it had a population of 144,000, of whom one-third were foreign born, with Italians, Poles, and Hungarians predominating in that group. The midwife did practically all of the obstetrical work among these women, attending as a matter of fact over one-third of the deliveries in the city.

At the beginning of 1921 the Department of Health definitely took over the infant welfare work with the avowed purpose of further reducing the infant mortality. The question then arose as to what might be the best method of establishing contact with the mothers and of following the babies through their first year of life.

The health officer in Bridgeport is the registrar of vital statistics. It was decided to have nurses from the department deliver birth certificates to the mothers as soon as possible after the registration of

births. To this end the city was divided into districts, with a nurse in each; well baby stations or, as they are called in Bridgeport, health stations, were opened in school buildings in different parts of the city. There are 5 stations today. Four are open one afternoon a week and another in a densely populated Italian district two afternoons a week. There is a doctor in attendance at each station.

At the outset the personnel of the newly organized division of infant welfare consisted of a director, a supervisor, 8 nurses and a clerk. The nurses in addition to performing the duties connected with the infant welfare program also did the communicable disease work. At no time have the nurses done infant work alone.

As time went on, a separate group of nurses was employed for communicable disease activities and the infant welfare and medical school inspection divisions were merged. That is how the organization is maintained at present.

Today the division is made up of a director, 2 supervisors—1 for each activity—22 nurses and 2 clerks. The city has been divided into 20 districts with a nurse in each. The nurse is responsible for all the child hygiene work in her territory, including that for the infant, the preschool and the school child. For the outlying districts an automobile is provided. The 2 remaining nurses are for relief.

During the school term the nurses spend the mornings in the schools and the afternoons in the field making such school home calls as are necessary, following up the infants, or are in the health stations. During the summer months, they are not engaged in infant work alone, but carry on any special activity that may be undertaken. For some years extra health stations for preschool children were opened during the summer months, but for the last two years this time has been used to a great extent in a toxin-antitoxin and Schick testing campaign.

Since the beginning, the main idea has been to get the coöperation of the mothers. When the nurse delivers the birth certificate to the mother she at the same visit gives the first of a series of 12 monthly letters. She explains the purpose of the infant welfare work, tells of the health stations, and talks over the general care of the baby.

The letters of the series are very simple. They are dated "Baby's First Month," and so on, up to the 12th month. They tell of certain common dangers to and certain common measures for the baby's health, what the mother may expect of the average child at different times, and urge her to seek advice from the family doctor at once when anything unusual develops in the infant's condition.

At the health stations the babies are weighed and measured. The doctor in attendance examines those brought to him, supervises feed-

ing, and prescribes for minor ailments. Physicians' private patients are referred back by the nurse. Children found ill are sent to their own doctor or to such agency as the doctor may think best suited to care for those particular children. The importance of breast feeding is emphasized and premature or unnecessary weaning is often prevented. Attempts are made to bring home the idea of keeping the baby well.

This work has now been carried on for 7 years. What has been accomplished?

To be sure there had been a downward trend in the infant mortality rate before the Department of Health made any special effort to lower it. The average rate from 1911 to 1915 was 109. From 1916 to 1920 it was 93.1. For the year 1920 it was 92.1. Since the department began the work the rate has not been above 80. The average rate for the last 7 years is 63.3. For 1927 it was 42.5, the lowest ever recorded for the city. Had that for 1927 been the same as 1920 there would have been 288 deaths in that year instead of 133.

TABLE I
DEATHS PER 1,000 BIRTHS FROM THE FIVE PRINCIPAL CAUSES

	1920	1921	1922	1923	1924	1925	1926	1927
Prematurity	18.9	13.1	11.4	11.7	15.2	12.4	17.3	12.4
Respiratory Diseases	18.9	10.2	13.5	15.3	10.0	10.1	13.7	6.0
Congenital Malformations	10.2	6.8	5.8	8.2	4.5	6.4	4.2	3.5
Birth Injuries	5.2	5.8	3.5	8.8	4.8	7.6	6.5	4.4
Enteritis	16.9	9.9	5.8	3.0	2.4	3.5	4.2	0.9
Infant Deaths	385	271	220	261	183	164	223	183
Births	4178	4116	3406	3265	3282	3063	3055	3123
Infant Mortality Rate	92.1	65.8	64.5	79.9	55.7	53.5	79.2	42.5

It will be seen that there was a rise in 1923 to 79.9 and that there was in that year a rise in the rates for prematurity and the respiratory diseases. Respiratory complications accompanying or following measles were the cause of 20 infant deaths. The rate for prematurity was the highest since 1920.

Again in 1926 there was a rise to 79.2, almost as high as in 1923, and once more there was a rise in the rates for prematurity and the respiratory diseases. In 1927 with the lowest rate in the history of the city there was a drop in the rate for prematurity and a surprising drop in that for the respiratory diseases.

In Bridgeport the gastrointestinal diseases as causes of death are almost negligible, due in large measure to the fact that 95 per cent of the milk sold in the city is pasteurized. Prematurity and the respiratory diseases remain the two principal causes of infant deaths.

Just how the respiratory disease rate can be lowered is a, or the, question. The nurses in their visits stress the importance of guarding

against and promptly treating colds. There may be no satisfactory treatment for a cold, but mothers can understand that rest in bed and forcing fluids may do something to prevent the development of a more serious respiratory complication. Mothers are urged to call the doctor early in these cases and every endeavor is made to educate them to a realization of the fact that the common cold is a source of danger.

Statistics alone may not be a satisfactory index of the quality of the work done, but the number of calls gives a good idea.

Infant welfare calls were as follows: 1921, 18,412; 1922, 41,971; 1923, 50,079; 1924, 60,876; 1925, 57,247; 1926, 52,333; and 1927, 62,024.

From the beginning, the health stations have been well attended. During the entire time over 30 per cent of the babies born and residing in the city have been registered at these stations. The attendance and new registration is shown in Table II.

TABLE II
HEALTH STATION ATTENDANCE

	Total	Under 1 Year	New Registration under 1 Year
1921	6,258	4,824	
1922	7,107	5,020	1,028
1923	7,422	4,813	972
1924	7,560	5,156	975
1925	8,833	6,355	985
1926	6,930	4,876	747
1927	9,280	6,079	876

The budget for the Division of Child Hygiene in 1927 was \$41,340.00. Taking one-half for infant welfare work gives that branch \$20,670.00, which makes the cost of keeping in touch with the baby at home and at the Health Stations 28.9 cents per visit. This figure has been made possible by eliminating special nurses for the different phases of child hygiene work and having each do her part in the program as a whole.

SUMMARY

The Department of Health of Bridgeport has been trying to reduce the infant mortality rate for the last 7 years. It started this undertaking with a corps of 9 nurses, and today employs 22. Only a part of their time is devoted to this work. During this period the rate has fallen from 92.1 in 1920 to 42.5 in 1927, with rises to 79.9 in 1923 and to 79.2 in 1926, attributable to increases in the deaths from respiratory diseases. These and prematurity are the outstanding causes of infant mortality, and for further reduction special endeavors must be made in this direction. The cost of following up an infant in 1927 was 28.9 cents per visit.

Diphtheria, Its Treatment and Prevention

WALTER W. LEE, M. D.

Epidemiologist, Indiana State Board of Health, Indianapolis, Ind.

A STUDY of diphtheria mortality during the past half century in the states, provinces and cities of the United States, Canada and Europe was made to learn:

1. The extent of diphtheria mortality and its variation from year to year
2. The effect on diphtheria mortality due to the use of antitoxin
3. The extent of the use of diphtheria immunization
4. Its effect on diphtheria mortality

For the purpose of this study, data have been plotted on semi-logarithmic paper in order to demonstrate the trends in the various data. Diphtheria death rates, in common with many biological data of progressing or regressing events, follow a curvilinear trend, so that when the same data are plotted on semi-logarithmic paper the trend becomes a straight line. Therefore, semi-logarithmic paper is the paper of choice, or plain cross-section paper may be used on which one can plot the logarithms of the data. The resulting graphs will be identical. Diphtheria mortality rates for Massachusetts, plotted on plain cross-section paper, Figure I as numbers, and Figure II as the logarithms of the data, illustrate this point.

It is now about 33 years since diphtheria antitoxin was given to the world as a specific treatment for diphtheria. Prior to 1895, the crude death rate from diphtheria was around 100 per year with a wide range of variation, differing in different communities; physicians watched with dread, and were helpless to combat the rapid and fatal course of this disease. But with the introduction of antitoxin, the scene was changed. Men who had many times stood helplessly by and beaten, now, by the aid of this wonderful new specific, were able to treat with success. They watched with justifiable pride the rapid clearing of the membrane and dramatic recovery of the patient.

Hospitals saw their diphtheria mortality rates cut in two, following the introduction of antitoxin, and apparently a new day had dawned in which diphtheria, the great scourge of pediatrics, was to be laid low and fade off into history as an awful nightmare.

Since 1895, the use of diphtheria antitoxin as a therapeutic agent

has become practically universal. It was rapidly adopted by the profession and accepted by the laity. Year by year cases were seen, diagnosed and treated earlier, and with larger doses of serum, and yet diphtheria is with us still and is one of the chief causes of death from acute infections in childhood. We often point with pride to our declining mortality rates and show how we are conquering diphtheria. Occasionally when we get a run of luck and find a series of years showing a marked downward slope in mortality rates, we get quite beside ourselves in our enthusiasm over how we are bringing down our diphtheria mortality.

Now after a period of 33 years of experience with the use of anti-

toxin let us pause and look back over our trail and consider whether we have taken full advantage of the opportunity afforded by so potent a drug as antitoxin. Is diphtheria as thoroughly beaten as we had reason to expect 33 years ago? If not, then, why not? What have we done to eradicate diphtheria since the introduction of active immunization? Have we made the most of our opportunities in that respect? If not, why not?

In a paper read before the National Academy of Science, November 9, 1926, Doering showed that diphtheria rates in Massachusetts from 1875 to 1925 fall about a trend line within the range of chance distribution, and the trend is certainly not markedly changed in direction when passing through the period following 1895.

What Doering found to be true for Massachusetts is also true, in a general way, for other countries, states and cities. If data showing diphtheria mortality rates extending back to 1870 or further, for large communities, are plotted, one can see that there are two general trends. The first, in respect to time, can be drawn forward and is found to leave the course of mortality-rate-frequencies somewhere between 1890 and 1900. On the other hand, a trend line can be drawn, starting at 1925 and drawing it backward, which will not leave the course of mortality frequencies until about the year 1880 or 1890. In no instance do the data of diphtheria mortality rates show a marked drop in their trend when passing into the range of influence of the therapeutic use of diphtheria antitoxin.

Observe the graphs in Figure II. Note that the trend of the data for Massachusetts has been continuously downward at an unvarying slope for 20 years prior to the introduction of antitoxin in 1895 and since, to date. In New York City, where the factor of population density would obviously influence the mortality rates from any communicable disease, the tendency for the mortality rates to fall was not noticeably marked until 1894, but note that a trend line can be drawn in from 1885 to 1925, and throughout its extent the mortality frequencies fall well within the range of chance deviation from the trend line.

Observe the upper dotted line representing mortality rates for the 0-4 age group in New York City. Two lines are drawn in showing two possible trends. The shorter line fits the data more closely and, if accepted as the true trend of the data, then it is apparent that the introduction and use of antitoxin in 1895 was responsible for the drop in death rates from 1894 to 1898 which was relatively greater in the 0-4 age group than in the city at large. On the other hand, with an increase in the use of antitoxin the fall in rates from 1898 to 1921 was less rapid in the 0-4 age group than in the city as a whole. The writer believes that the longer line gives a more accurate picture of the general trend of the fall of the mortality rates in this age group. In only three instances do the mortality frequencies vary more than twice the standard deviation from the trend line, and that only prior to 1900, since when diphtheria mortality rates have tended to become more stable due no doubt to the use of antitoxin. Such a trend conforms more to the general trends in other states and cities. If the longer line is accepted as the probable trend of the data for this group, then one must concede that although, without a doubt, antitoxin has been a real influence in the lowering of death rates there are other factors operating toward the same end.

Figure III for England and Wales is of special interest because of the stability of the data, due to the size of the population (35,000,000). There is a fall in the trend representing a fall in death rates from approximately 35 to 10. Is this fall in diphtheria mortality rate the fall one would expect following the universal use of so specific a drug as diphtheria antitoxin? True, the change in trend begins in the region of 1895, but mark also that scarlet fever, for which there was at that time no specific treatment or preventive, has been falling along a trend practically parallel to that of diphtheria. Smallpox also is much less virulent now than it was in the last century. Diseases tend to wax and wane in their prevalence and virulence. Has diphtheria fallen because of our use of antitoxin, or would it have fallen without it? Has diphtheria become less prevalent than it used to be? It is doubtful. Is it less virulent, or is the population less susceptible than in the last century? The answer is necessarily a matter for conjecture.

Why is it that Toronto, Ont., and Cleveland, O., are having diphtheria death rates around 20, while the average for the country as a whole is around 8 or 9? Both are university cities with medical men second to none. Both have antitoxin in unlimited quantities. Why are most of the cities about the Great Lakes having such high death

rates from diphtheria? In other words, how much are we actually controlling diphtheria, on a country-wide basis, by means of treatment?

In Figure IV, the data showing diphtheria deaths in Massachusetts since 1890 are plotted against data showing units of antitoxin produced by the biological laboratories of Massachusetts. The latter data are inverted to show the relation in the trends for both data. It is not safe to draw conclusions from one state only. It is offered here only because it is of interest. Note, however, that in spite of the tremendous increase in the use of antitoxin the trend of the deaths continues unchanged from that prior to the introduction of antitoxin. The value of antitoxin in the treatment of diphtheria has long since passed the experimental stage and needs no verification here. Probably if every case of diphtheria were seen early enough, diagnosed and treated with an adequate dose of antitoxin, there would be few if any deaths. Why then do not mortality rates show more evidence of this effect of antitoxin? The following illustrates one reason. The treatment of diphtheria is necessarily intimately bound up with a large human factor, and human nature is naturally prone to err. Early and

adequate treatments are essentials of successful therapy in diphtheria. The onset of diphtheria is often so insidious that the case is well advanced before the mother is sufficiently alarmed to call a physician. Physicians are only human and have been known to miss the diagnosis. Too often the physician delays treatment while he waits for a laboratory report on the throat smear. The laboratory is operated by human beings and they, though usually right, have also been known to be in error. After the diagnosis, the treatment varies—another human factor.

Since 1926, the writer has studied 297 diphtheria deaths in Indiana. A similar study of 500 diphtheria deaths in New York State was made by Roberts. Together the findings are in part shown in Table I.

TABLE I
STUDIES OF 797 DEATHS FROM DIPHTHERIA

	New York Per Cent	Indiana Per Cent
Physician called after third day of illness	40.0	49.5
Antitoxin administered in repeated doses	33.0	39.7
Antitoxin not given at first visit	40.0	35.0
Antitoxin not given at all	10.6	10.0

On the basis of the above studies of 797 deaths in two states, over 40 per cent of the deaths followed late treatment, and, together with 10 per cent that did not get any antitoxin, make up half the deaths. In over one-third of the deaths, antitoxin was not administered on the physician's first visit. In these cases, after the physician was called, he apparently waited on the laboratory report or missed the diagnosis on his first call. Another delay, and the most unpardonable sin of all, was that in over one-third of the cases antitoxin was given in repeated doses instead of a single adequate dose. Every physician knows that antitoxin does cure diphtheria patients when given early and in adequate dosage. The reason that mortality data do not show more evidence of the value of antitoxin in the reduction of diphtheria mortality rates is found, not in any lack of potency in antitoxin itself, but rather in our administration of it.

The picture, however, is not entirely black and one must not conclude that because crude diphtheria mortality rates do not as a rule show marked reduction following the use of antitoxin, antitoxin has been a failure. This article is written from the viewpoint of the health officer interested in the state- or nation-wide control and elimination of diphtheria, not from the viewpoint of the physician who is interested in the treatment of an individual case. From the latter viewpoint there is probably nothing in medicine that is nearer 100 per cent perfect than antitoxin in the treatment of diphtheria, when given

early and in adequate dosage; but, on the other hand, judging from our experience of 33 years in the use of antitoxin, it is doubtful whether antitoxin has been anything more than one of several factors operating to reduce the general diphtheria mortality. If one were to look at the plotted data with the dates removed from the graphs, it would be impossible to point to a period and be able to say with assurance, "Antitoxin must have been introduced here or there." The change in trend in the last 50 years has been definite and significant, but gradual, all the way.

Now let us observe the data for specific age groups for Massachusetts since 1890 (Figure V). It will be seen that there has been a marked falling off in the mortality rates of the 0-4 age group. The data for the age groups for 1890 and 1925, changed back to numbers, are given in Table II, averages taken from the trend lines. Note the

TABLE II

1890			1925			Change
Age Groups	Death Rates	Percentage	Age Groups	Death Rates	Percentage	
0-4	462.0	64.8	0-4	58.1	57.3	- 7.5
5-9	199.0	27.9	5-9	34.1	33.7	+ 5.8
10-14	39.8	5.6	10-14	6.8	6.7	+ 1.1
15-19	10.0	1.4	15-19	2.0	2.0	+ 0.6

shifting of the mortality percentages from the first age groups to the 5-9 age group. Is this due to the use of antitoxin or to some other factor? Whatever the cause, it has been, no doubt, a potent factor in reducing the death rates since about two-thirds of the deaths occur in the 0-4 age group.

In the last decade much information concerning diphtheria immunization has been compiled and disseminated. Results of the Schick test have been very well studied, so that now we have very good data relative to the natural susceptibility of the various age groups. A large number of children have been immunized, but unfortunately most of this work has been done among the school children and very little among the preschool population. The school children are easily handled in a general immunization campaign, while it is relatively difficult to get the preschool children to the clinic.

TABLE III

RATIO OF PROBABILITY OF DYING OF EACH AGE GROUP ON THE BASIS OF 10-14 AGE GROUP AS 1				
Age Groups	0-4	5-9	10-14	15-20
1890	11.6	5	1	0.25
1925	8.5	5	1	0.3

Table III for Massachusetts shows the relative importance of conducting immunization among the various age groups. Take for example the relative value of the immunization of a child 14 years of

age and one under 1 year. In 1 year the 14-year-old child will be in a relatively non-susceptible group, while the infant will be for 15 years in the relatively highly susceptible age groups. Therefore, during the 5 years the infant is in the 0-4 age group he will be the equivalent of over forty-two 14-year-old children. In the next age group, 5-9, he will be the equivalent of twenty-five 14-year-old children. He will be in the 10-14 age group, for 5 years, the equivalent of five 14-year-old children. Thus the immunization of one infant at 6 months of age is the equivalent of immunizing over seventy-two 14-year-old children, other ages in proportion.

Apply the above to an average city of 100,000 people, with an expected death rate of 10 per annum, and the deaths will be divided approximately as shown in Table IV.

TABLE IV

Age Groups	0-4	5-9	10-14	15-
Populations	10,000	10,000	10,000	70,000
Expected Deaths	6	3 or 4	0 or 1	0 or 1

If we can prevent 1 death in any one age group we will lower the crude death rate by 1. Obviously, if we could protect one-sixth of the first age group, about 1,700, or one-third of the second age group, about 3,300, we could expect to prevent 1 death. If we could immunize 5,000 in each of the first two age groups we would, on the basis of this simple calculation, reduce the deaths by one-half. But, as a matter of fact, the experience of cities, where immunization has been intensively carried out, goes to show that the immunization of half the susceptible children will nearly, if not actually, eliminate diphtheria from the city.

On the other hand, how many children of the 10-14 age group must we immunize to expect a reduction of 1 death? Probably 20,000—and there are only 10,000 in the 10-14 age group—and in the ordinary course of events, without any immunization at all in this age group, there is an even chance that there will be no deaths anyway. In any event, the immunization of all children under 10 years of age will remove the sources of infection, the older age groups will cease to be infected and in this way will take care of themselves.

These simple calculations, though based on the facts of the experience of Massachusetts for 36 years, are purely hypothetical and are offered here merely to show the relative importance of concentrating our efforts in immunization on the most susceptible age groups under 10 years of age. This probably suggests why so much of the immunization work done in the past shows no significant reduction in the crude diphtheria mortality rates.

During the last four or five years many states and cities have experienced a marked fall in diphtheria mortality rates, and likewise many persons have credited it to the immunization work that has been done. This makes propaganda of doubtful value, for in most instances if the data are observed over a long period of time, it will be found that the recent drop is only what we would expect from the operation of chance only. There are exceedingly few communities with data showing significant reduction in diphtheria rates following intensive immunization work.

In this survey the following cities show significant reduction in their death rates following intensive immunization work:

Hamilton, Ont., a city of 124,000 population, began immunization in 1922 since when they have immunized between 20,000 and 25,000 children. Unfortunately more definite data are not available. Children under 15 years of age com-

prise approximately one-third of the population; therefore Hamilton has immunized about one-half of its child population. It is of interest to note that this work has been done with anatoxin and not toxin-antitoxin. Irrespective of the relative value of the two methods of developing active immunization, they work equally well if the work is done thoroughly. In 1927 this city had 11 cases of diphtheria and 1 death. This is a marked and highly significant reduction from the rather high diphtheria mortality rate prior to 1922 as is shown by Figure VI.

New Haven, Conn., is a city of about 185,000 population. They began immunization of their school children in 1923 with the following results: In 1924, there were 11,747 children immunized; in 1925, 9,649; in 1926, 6,888; in 1927, 4,900; making a total of 33,184 children immunized. New Haven has now immunized about one-half of its susceptible population. In 1924 their death rate dropped significantly to 1.7; it was the same in 1925; in 1926 there was but 1 death, or a rate of 0.6; and in 1927 3 deaths, or a rate of 1.6. These figures are quite significant, as can be seen in Figure VII, and future results will be watched with interest.

Syracuse, N. Y., a city of 196,000 population, began immunization in 1923, since when over 23,000 children have been immunized or found immune. Here the child population is about 65,000 under 15 years of age. Their diphtheria death rate has dropped significantly since 1925 (Figure VII).

Auburn, N. Y., with a population of 35,700, has since 1922 immunized or found

naturally immune about 9,000 children. There are probably 12,000 children there under 15 years of age. The death rate dropped in 1924 to 2.7, after which it dropped to zero, where it stayed until January, 1928 (Figure VI). Since then there have been 2 deaths, 1 a child and 1 an adult, both treated with antitoxin late and never immunized. This has rather spoiled the record, through no fault of the public health authorities.

St. Paul, Minn., with a population of 298,000, has immunized nearly 26,000 children since 1924, and although the data, as shown in Figure VII, are over a rather too brief period from which to draw definite conclusions, they look significant. The future alone will show whether this drop is a streak of luck or the result of their immunization. The reports of cases from St. Paul during the past winter seem to indicate a continuance of the downward trend of diphtheria in this city.

Manchester, N. H., has been doing a considerable amount of immunization and will probably get a significant reduction in the next year or so.

Brantford, Ont., a city of about 30,000, with death rates from diphtheria of 7 in the 2 years, 1920 and 1921, dropped to 2 in 1922, zero in 1923, back to 2 in 1924, and has been zero since until 1928. They have immunized to date about 7,600 children. Their data are for too short a period, and their population so small that one hesitates to draw too definite conclusions as to the significance of their results, although what data are available look probably as significant as those of Auburn, N. Y. In 1928, the Health Officer reports 1 diphtheria death, after which 3,204 children were immunized. Our sympathies are all with the child who paid the supreme sacrifice for the negligence of someone, but perhaps, since the death was the means of protecting 3,204 other children from the possibility of a similar fate, the child may not have died in vain.

The dictum of the bloody days of old still holds in the 20th century—"Without the shedding of blood there can be no remission of sin." Surely enough blood has been spilled on the altar of ignorance and neglect to stir this nation into sufficient activity that it will take advantage of the discoveries of medical science which are at hand for the taking, and make the children safe from diphtheria.

Intensive immunization of the population under 10 years of age will control and probably eliminate diphtheria.

SUMMARY

1. Although diphtheria antitoxin, when given early and in adequate dosage, is one of the most efficient of all our specific drugs, yet from our experience of 33 years in this country, it has been but one of the factors in the reduction of diphtheria mortality rates. In most cities and states in which data show diphtheria mortality rates prior to 1895, it is found that the trend of the fall of mortality began from 5 to 20 years prior to the introduction of antitoxin and has continued ever since unchanged save by the fluctuations due to chance.

2. Scarlet fever mortality, for which we had no specific therapy, has fallen along a trend practically parallel to that of diphtheria.

3. A study of nearly 800 diphtheria deaths in the states of Indiana and New York reveals that even now, after 33 years of experience with antitoxin, over 40 per cent of our diphtheria deaths occur in cases sick over 3 days before a physician is called; 10 per cent of the deaths occur without receiving any antitoxin at all;

35 per cent are given antitoxin in repeated doses, although this practice has been condemned for years; and in about 35 per cent of deaths antitoxin was not given on the physician's first visit. Any failure on the part of antitoxin to reduce the general diphtheria mortality rates is not due to failure on the part of the drug but rather to our administration of it.

4. Since 1920 there has been a general and marked fall in diphtheria death rates, which is often attributed to the use of toxin-antitoxin. If these data for these states or cities are observed over a long period of time it will be found that in most instances the present fall of mortality rates is well within the range of chance deviation from the general trend line, and is entirely insignificant, due, no doubt, in most cases at least, solely to the operation of chance.

5. Although diphtheria antitoxin has apparently played but a minor rôle in the general reduction in diphtheria mortality rates since 1890, this disease is being controlled and may even be eliminated by the intensive use of diphtheria immunization in the child population. To date the writer knows of only 6 cities where this has been done sufficiently intensively to significantly reduce the diphtheria mortality. There are other cities, no doubt, with similar results which have not come to the writer's notice.

6. In cities where immunization work has been done sufficiently to reduce the mortality rates significantly, it has been accomplished after about one-half of the child population under 15 years of age has been immunized. Unfortunately, detailed information as to the number of children in specific age groups is often lacking. Such data during the next few years would be invaluable.

7. Since about 60 per cent of the deaths from diphtheria occur under 5 years of age, and about 35 per cent between 5 and 10 years of age, or 95 per cent of deaths occur in children under 10 years of age, it is obvious that in an immunization campaign the work should be concentrated upon the children under 10 years of age, and especially upon the preschool children. This last group is the hardest to reach; yet it holds the key position in all immunization work and our efforts will necessarily be relatively unsuccessful as we neglect this group.

NOTE: The writer wishes to thank all the health officers who have so generously furnished the data which have made this study possible.

Childbirth and Fear

IN a certain sense it may truly be said that fear rules the world. At any rate, it enters into most persons' lives in a most disconcerting fashion. And confidence casts out fear—especially confidence based on knowledge, according to Eardley Holland in discussing the midwives of Sweden. In that country midwives are required to have a good education before beginning the study of midwifery, a training which lasts two years. The medical student, in that country, also gets an excellent training in midwifery. The result of it all, according to Holland, is an "atmosphere of confidence" on the part of the public which "has a profound influence in producing easy labor." All normal confinements there are handled by midwives, but in the abnormal cases there is an adequate supply of well-trained obstetricians upon whom to call.

Dr. Holland thinks that England and America might well profit by Sweden's example.—Editorial—*Maternity and Child Welfare*, Aug., 1928.

Heart Disease and School Life

JOSEPH H. BAINTON, M.D.

*Heart Committee, New York Tuberculosis and Health Association,
New York, N. Y.*

LIMITATION of an individual's capacity for physical activity is the penalty imposed by heart disease. To understand the cause of this restricted physical ability, it is essential that one have a fundamental knowledge of the physiology of the heart and an appreciation of the changes in its function which result from damage to its structure. Without this intelligent background competent supervision is impossible and the cardiac child is liable to unconscious neglect or over-anxious solicitude.

Normal healthy life is impossible without an adequate circulation of the blood. The flow of blood must be continuous and at the same time distributed in amounts which will vary in accordance with the physiological needs of the different parts of the body. Muscle at rest requires a certain amount of blood, while muscle in action calls for an increased supply which is proportionate to the energy expended.

It is quite obvious that the heart which is the pumping force behind the circulation will have the least amount of work to do when the body is in the condition of complete physical rest. Muscular activity demanding a greater output of blood increases the work of the heart, the maximum expenditure of energy for any individual depending on the ability of his heart to propel the requisite amount of blood. This is true for both normal and diseased hearts.

It is not expected that a man accustomed to heavy work and one of sedentary habits will have the same capacity for physical exertion; but it is expected that every healthy heart will have the power to meet the demands of the ordinary physical activities of daily life. This ability to perform the ordinary activities of life is a standard by which we can estimate the functional capacity of the heart.

In using such a standard one must exclude some extraneous conditions such as acute and chronic infections, anemia, obesity, convalescence and injury or deformity, which may adversely affect the strength of the heart muscle and all the muscles of the body. But other things being equal, individuals of similar physique and habits are expected to show the same reaction to physical exertion.

Inability of the heart to propel enough blood to permit the ordinary

activities without undue discomfort constitutes heart failure. Heart failure does not occur in healthy people. It is a result of heart disease.

Disease may attack the heart in any of its structural elements and destroy the integrity of the mechanism on which the circulation of the blood depends. A damaged heart however may so adjust itself that normal physical activity is possible, or it may be so handicapped that an individual is incapable of performing the ordinary tasks of daily life without discomfort. This handicap will vary in degree. It may be so mild that only slight limitation of activity is imposed, or so severe that no exertion is possible and absolute rest in bed is imperative.

Organic heart disease may be divided into two stages, active and inactive. During the active stage inflammation is actually present in the tissues of the heart. When all evidence of the activity of the infection has disappeared healing takes place by the formation of scar tissue. This is the inactive stage. The progress of the disease has been halted but structural damage remains.

In children the activity of the infection within the heart, more than the mechanical damage to its structure, is the determining factor in heart failure. When the infection becomes inactive children with badly damaged hearts often become capable of carrying on the activities of daily life with little or no discomfort.

The incidence of heart disease among the school children of this country can only be roughly estimated at the present time. Figures are obtainable from only a few localities, and in interpreting these it is necessary to be quite certain that the methods of examination were uniform and the criteria for diagnosis fixed and well observed before it is possible to regard the data with confidence.

Of the 120,000 school children examined in Boston 2,311 were suspected of having heart disease and were referred for special cardiac examination. Of these 625 were found to have organic heart disease. In addition to these there were 160 children of school age but not attending school who had organic heart disease.

The figures for New York were obtained in the routine examination by the physicians of the Department of Health, Bureau of Child Hygiene. On reexamination of some of these children under more favorable conditions and with clothing removed from the chest the figure was reduced to 7 per 1,000. It is rather significant that in 1924, in a routine examination of a large sample (598,167) of children from the elementary schools of the whole of England and Wales, 7 per 1,000 (4,285) were found to have organic heart disease.

Until such time as the adequate physical examination of children is a routine practice, many cases of heart disease will escape detection

TABLE I

INCIDENCE OF ORGANIC HEART DISEASE IN SCHOOL CHILDREN OF LARGE CITIES

City	Year	Number Examined	Rate per 1,000
Philadelphia ¹	1924	23,671	6.3
Boston ²	1926	119,337	6.6
Chicago ³	1923	158,826	9.0
Chicago ⁴	1924	153,671	15.0
Chicago ⁵	1925	130,266	17.0
New York ⁶	1918	250,000	16.0
New York ⁷	1918-1922	1,336,343	13.9

⁷ Report of the Committee on Schools of The Association for the Prevention and Relief of Heart Disease, June 14, 1923.

and purely functional disturbances will be wrongly diagnosed as organic heart disease. A satisfactory knowledge of a child's physical defects could be obtained by an examination at the time of admission to school, by reexamination when returning to school after a period of illness, and by a thorough reexamination at regularly fixed periods.

In most localities the medical school officer is not legally permitted to remove the clothing from the chest to make an examination. Under such circumstances a proper diagnosis can be obtained only by referring suspected cases to their private physician or, when they are unable to pay, to a cardiac clinic.

The detection of organic heart disease in a child is only the first step in the problem of its care. Classification of these children according to the degree of limitation of their physical capacity is necessary for intelligent supervision.

For the purpose of defining the different degrees of functional capacity of the heart, the American Heart Association has adopted a non-technical classification which defines the physical ability of the patient as modified by the condition of his heart.

The systematic registration of cardiac pupils in accordance with this classification will permit some definite standardization, will curtail unnecessary absences, will guide in physical exercises and in the supervision of the ordinary exertions incident to the daily school life.

THE CLASSIFICATION

Class I—Patients with organic heart disease able to carry on ordinary physical activity without discomfort

Class II—Patients with organic heart disease unable to carry on ordinary physical activity without discomfort

A—Activity slightly limited

B—Activity greatly limited

Class III—Patients with organic heart disease and with symptoms or signs of heart failure at rest, unable to carry on any physical activity without discomfort

Class E—Possible heart disease. Patients who show abnormal signs and symptoms referable to the heart but in whom the diagnosis of heart disease is uncertain

Class F—Potential heart disease. Patients without heart disease, whom it is advisable to follow because of the presence of a history of an etiological factor which might cause heart disease (in such cases the etiological factor should be stated)

Class I—These children have no symptoms and their physical capabilities are the same as healthy children. Unless reinfection occurs the heart condition is stationary. Accordingly they need but little supervision. They can indulge in the same exercises and pastimes as other children; but by way of precaution it is wise to place some limit on their physical activities. They should not be permitted to engage in competitive athletics or to indulge in games which demand sudden severe physical strain.

Class II A—These children are capable of performing the ordinary activities of childhood, but extraordinary exertions such as fast running, vigorous play, hurrying upstairs produce undue breathlessness and fatigue which are apparent to any attentive observer. Games and exercises which produce only temporary shortness of breath in healthy children are too strenuous for the cardiac children of this class. Running, skipping the rope, prolonged tiring drills should not be permitted. They may enter classes of physical culture but should be compelled to rest during any part of an exercise which unduly tires them.

Class II B—The physical ability of children in this class is noticeably limited. The vast majority have active heart infection as indicated by some degree of fever and a typical white blood cell count. They are sick children and though some of them may be physically able to attend school they should be at rest in bed. It is especially important that children in this class be recognized, because attendance at school is further detrimental to their health. Parents should be informed that these children are unfit for school, that they should be at home and under the care of a physician till all signs of activity of the heart infection have disappeared. After convalescence these children can return to school, being reclassified in Class II A or Class I.

Some children with congenital heart disease have a decided limitation of their physical ability, and occasionally a child with acquired heart disease may have had the heart so severely damaged that his limitation of physical activity is quite marked even in the absence of active infection. Education is merely a passing event with such chil-

dren. All of them will be unfit for any future occupation and their expectancy of life does not reach adult years. These children should not be permitted to climb stairs. If regularly present at school they may be placed in a class with other children who are physically handicapped.

Class III—It is unnecessary to consider the children in this class more than to state that they should not go to school. They are compelled to remain in bed because of the degree of failure of their hearts. Exceptionally, when proper supervision is not maintained, a child in this class may manage to attend school at irregular periods. This is dangerous to the life of the child and should not be permitted.

RECLASSIFICATION

Some children do not remain permanently in the same class. Children in Class I may revert to Class II A, II B or III, or conversely children in the poorer classes may improve and require reclassification on a higher basis. The presence or absence of infection in the heart is usually the cause of change in symptoms which determine the altered classification. The child's school activities should change in accordance with a reclassification.

E—Possible Heart Disease—It is impossible to outline any definite regulations for the physical activities of these children. Limitation may or may not be advisable. The necessary restriction should be determined by the physician of each individual child.

F—Potential Heart Disease—As a cause of heart disease in childhood, rheumatic infection stands preëminent. It has been estimated that as high as 97 per cent of heart disease in childhood is due to rheumatism. It is also claimed that 75 per cent of children who have rheumatism develop organic heart disease. Chorea, or St. Vitus' dance, and growing pains are but different manifestations of rheumatic infection. Some cases of tonsillitis are suspected of being due to the same infection. Scarlet fever is frequently followed by rheumatic symptoms. The actual presence of heart disease which has been caused by these conditions may not be manifested till several months or years later, but during all this period it is essential that the child be under the observation of a physician and that its activities be regulated according to his orders.

REGISTRATION

In a school of 1,500 pupils there would be found probably 10, at the outside 20, children with organic heart disease. From figures available, it can be estimated that 55 per cent of these children are in Class I, 33 per cent in Class II A, 7 per cent in Class II B and 1 per cent in Class III. Translated into numbers: for a school of 1,500 pupils

with a maximum figure of 20 cardiac children one would expect to find 11 children in Class I, about 7 in Class II A, and occasionally a child in Class II B and Class III. This means that the number of children with organic heart disease attending a school of this size would not exceed 18, and probably would be as low as 9 or 10. If to these we add the children who are classified as potential cardiacs, the number will be increased somewhat, but it is still very small when compared with the total school attendance. To supervise properly even this small number of children it is necessary to keep a register. Individual cards for each child, specifying its classification, physical and nutritional defects, can be kept on file, the family or clinic physician being responsible for the data.

GENERAL MEASURES

Aside from heart disease, these children present the same problems in general health as do other children. But in their case it is probably more important that a special effort be made to build up the natural resistance to infection, with the hope of preventing further damage to the heart already diseased.

Measures calculated to attain this end are:

1. Improvement in general nutrition by good food, sufficient sleep, fresh air both day and night, summer vacations in the country
2. Best possible home conditions, eliminating as far as possible the privations of poverty and unhygienic living and sleeping quarters
3. Proper clothing for the different seasons of the year
4. Avoidance of physical strain (unwise parents and guardians may compel cardiac children to perform tasks and household work beyond their capabilities)
5. Institution of those methods which have been found valuable in protection against infectious diseases
6. Correction of physical defects: Eradication of possible foci of infection, especially diseased tonsils and decayed teeth
7. In some districts the provision of transportation to and from school
8. The same protective supervision exercised in school, carried into the hours beyond the school day and into the vacation periods

Such a régime can be instituted and carried out only by the co-operation of the school authorities, the parents, the physician, the nurse, the social worker, welfare agencies and departments of health.

The school nurse or social worker should see that all children with heart disease and those with possible or potential heart disease are under the observation of their own physicians or a cardiac clinic. A visit at least once in three months is desirable, but in some cases it may be necessary to see a physician at shorter intervals.

The actual instruction of a cardiac child should present no more difficulties than are found in the case of the average healthy child. A child with heart disease who is fit to attend school is just as keen

mentally and just as receptive as other children. Attendance at classes is the principal incidental problem. However, "it is not detrimental for children with heart disease to make a perfect score in attendance; for a large number of them do so." Many absences are entirely unnecessary because of a "too ready acquiescence in the child's desire to remain away from school." A careful follow-up in New York showed that "63 per cent of absences were for reasons entirely unconnected with disease of the heart." Holidays, truancy, weather, and family social events accounted for 37 per cent, minor ills for 26 per cent.

It is incumbent on the school authorities to encourage these children to continue their education beyond the elementary grades. Parents should be enlightened on this phase of the problem and informed that "adequate education is more essential for the cardiac child than for the average healthy child, since this opens to him opportunities of employment and amusement which are more likely to conform to his capacity for physical exertion. Most of the work of the uneducated and unskilled is of the laborious nature," and therefore unsuitable for people with heart disease.

In children, physical exertion is not a significant factor in the production of heart failure, while in the adult with heart disease it is probably the most frequent cause of a cardiac breakdown. But inasmuch as these children are being prepared for adult life, their education must be directed along lines which will enable them to engage in occupations which will not require undue physical exertion.

Children who are in a position to continue their education through high school and even through college will be fitted for employment in which the danger of overstrain can be practically eliminated. Those children who for various reasons are unable to pursue the higher courses may enter a trade school and be taught manual work which will prepare them for positions in which technical skill and not physical strength is requisite.

Children with heart disease should know that they are handicapped, but at the same time they should have a true appreciation of this handicap. The school training should make them realize that within their limitations they can lead useful and happy lives.

Exercise and physical exertion which do not overtax the heart, improve the physical fitness of people with heart disease.

Morbid fear of heart disease and distorted sense of its dangers lead to a life of unhappy indolence.

The Minimal "Chlorine Death Points" of Bacteria

I. Vegetative Forms

FRED O. TONNEY, M.D., FRANK E. GREER,
and
T. F. DANFORTH, D. V. M.

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

ALTHOUGH chlorine gas is universally used in the treatment of water supplies, and its derivatives are finding an ever increasing field of usefulness in the disinfection of milk and beverage bottles, dishes, and utensils of various kinds, little is known of the actual or relative amounts of chlorine required to kill specific species of organisms under given conditions. The amount of available chlorine used in practical chlorination has been arrived at empirically or indirectly, and in many instances is probably far in excess of the amount actually needed to destroy the pathogen under consideration. The amount of chlorine required to obtain satisfactory results varies with many factors, and especially with the kind of fluid or material to be sterilized.

Little, if any, work has been done to determine the least amount of chlorine required to kill known numbers of known species of bacteria under fixed conditions that admit of comparison of their relative resistance.

It has not been determined definitely what organism may be considered a safe index of effective chlorine treatment or whether a given organism can be used as an index under different conditions. *B. coli* has been almost universally accepted as the index of safety in the treatment of water supplies. Its acceptance, however, has been based largely on theoretical considerations and on the analogy of its greater resistance to heat and longer survival than the common pathogens which may be present in water.

For these reasons it was considered desirable to study the effect of chlorine on specific bacteria under controlled conditions to determine, if possible, the minimal dosage of free chlorine required to kill specific species of bacteria, to ascertain their relative resistance to free chlorine and, on the basis of these factors, to select, if possible, an organism that could be used as a safe index of effective chlorine disinfection.

In this article the methods used and results obtained with vegetative forms of bacteria are presented.

The methods of preparing the materials for the determinations were as follows:

The chlorine solution used was prepared by adding gaseous chlorine to distilled water until a final concentration of 60 p.p.m. of residual free chlorine was obtained. This served as a stock solution and was stored in a brown bottle in an icebox. At frequent intervals the free chlorine content of the solution was determined, and approximately every two weeks during the experiment a new stock solution was prepared.

The organisms tested included the common intestinal forms, and other pathogenic and non-pathogenic organisms, numbering in all 235 strains.

The intestinal organisms and *B. proteus*, *B. prodigiosus* and *B. pyocyaneus* were grown on agar slants. *Cl. welchii* was grown in glucose broth under anaerobic conditions. The streptococci and pneumococci were grown either in glucose broth or in a special streptococcus broth. The staphylococci were grown in glucose broth and the diphtheria organisms were grown in glucose broth, ascites fluid or serum glucose broth.

The cultures were centrifuged, washed, and resuspended three times in sterile distilled water. They were then diluted in sterile distilled water until a suitable number of organisms per c.c. were present.

The exposures to chlorine were made in sterile distilled water as a menstruum. One hundred and fifty c.c. of distilled water were placed in Pyrex Erlenmeyer flasks, and the contents and flasks were sterilized in an Arnold sterilizer. After the flasks had cooled to room temperature, 50 c.c. of the water in each flask were removed and the chlorine absorbing properties determined. Those flasks containing water showing any appreciable absorption were discarded. The remaining flasks were used for the experiments. The pH value of the water used ranged from 6.4 to 7.2. It is probable that the elimination of the water showing chlorine absorption also eliminated water of low or high pH value.

The tests were carried out by adding approximately 100 to 300 organisms per c.c. to the contents of each of two flasks. From one flask 1 c.c. was planted to determine the number of organisms present. Then a definite amount of free chlorine was added to each of the flasks. One flask was immediately subjected to chemical analysis to determine the amount of residual chlorine present. The other flask was

used for determining the rate of destruction of the organisms and the time required to kill. To do this 1 c.c. of the contents was plated at intervals of 8–10 seconds, 15 seconds, 30 seconds, 45 seconds and 60 seconds. The nutrient agar plates were poured immediately after transferring each 1 c.c. portion from the flasks. These plates were incubated for 48 hours at 37° C. At the end of this time the plates were counted and the rate of destruction and time required to kill the organisms present recorded. It was found that 48-hour incubation was necessary, because in many instances numerous colonies appeared in 48 hours on plates which in 24 hours had no visible colonies. For the organisms that would not grow in plain agar, slight variations of the above procedure were used. With such organisms it was not possible to establish the rate of destruction by chlorine, as no satisfactory means of counting them was available, either before or after the addition of the germicide. It was only possible to determine the length of time required to kill all of the organisms. For this purpose the contents of the flasks were streaked or planted in the type of medium in which the organisms were originally grown. The experiments were carried out at temperatures ranging from room temperature to within a few degrees of the freezing point of water.

RESULTS

The results are shown in Table I. It will be noted that all strains of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *B. enteriditis*, *B. dysenteriae*, *B. suipestifer*, *B. proteus*, *B. prodigiosus*, and *B. pyocyaneus* were killed in 15 seconds by a dosage of 0.1 p.p.m. of free chlorine.

Many of the strains of streptococci of both hemolytic and fecal types were also killed by this amount of chlorine, as were all the strains of *Cl. welchii* (vegetative cells) and most of the strains of *C. diphtheriae*. In some instances slightly longer periods of time, i.e., 30 to 45 seconds, were required to kill all the organisms at the concentration of 0.1 p.p.m.

A few strains of pneumococci were slightly more resistant to chlorine than most of the other organisms. Four out of nine strains were killed by 0.1 p.p.m. of chlorine in 15 seconds. The remaining strains were killed by 0.2 p.p.m. of chlorine in less than 1 minute. The strains of *C. diphtheriae* not killed by 0.1 p.p.m. of chlorine were killed by 0.15 p.p.m. in 15 to 30 seconds.

Most of the strains of streptococci not killed by 0.1 p.p.m. of chlorine were killed by 0.15 or 0.20 p.p.m., although three strains were not killed until exposed to 0.25 p.p.m. of chlorine for 15 seconds to 30

TABLE I

DOSAGE OF FREE CHLORINE REQUIRED TO KILL VEGETATIVE CELLS OF BACTERIA IN 15-30 SECONDS

Chlorine p.p.m.	Species	No. of Strains	Species	No. of Strains
0.10	<i>B. typhosum</i>	21	<i>B. pyocyaneus</i>	6
	<i>B. paratyphosum A</i>	6	<i>C. diphtheriae</i>	27
	<i>B. paratyphosum B</i>	6	<i>Achromo bacterium viscosum</i>	3
	<i>B. dysenteriae</i>	8	<i>Strep. scarlatinae</i>	14
	<i>B. enteritidis</i>	4	<i>Strep. fecalis</i>	11
	<i>B. proteus</i>	2	<i>B. suispestifer</i>	8
	<i>Cl. welchii</i>	8	<i>B. prodigiosus</i>	6
	<i>Bruc. melitensis</i>	1	<i>Bruc. abortus</i>	1
	<i>Staph. albus</i>	4	<i>Staph. aureus</i>	4
	<i>Pneumococcus</i>	4	<i>Strep. hemolyticus</i>	11

Total Strains.....				235

seconds. These latter strains were of the hemolytic variety. Two were isolated from milk and one came from the Boston epidemic of streptococcus sore throat of 1911. It seems probable that the apparently higher resistance of these cocci to chlorine was due to the larger inoculum found necessary to obtain consistent growths. Considerably heavier inoculations of the streptococci were required than in the case of other organisms.

B. coli proved on the whole to be more resistant to free chlorine than the other organisms studied. None of the strains showed any appreciable reduction in number when exposed to 0.1 p.p.m. of chlorine. Nine strains were killed by 0.15 p.p.m. of chlorine, ten strains required 0.2 p.p.m., and nine required exposure for 15 seconds to 0.25 p.p.m. of chlorine for their complete destruction.

SUMMARY AND CONCLUSIONS

From these results it will be seen that a large majority of the vegetative types of organisms considered to be of sanitary importance in connection with water supplies, milk supplies, dish washing, bottle washing, and general disinfection, whether of intestinal or respiratory origin, are killed in a few seconds by rather small doses of free chlorine, when exposed in a suspension containing no organic matter or other substances that react with or absorb the chlorine. This was

found to be true for temperature ranges varying from room temperature to within a few degrees of the freezing point of water.

The amount of chlorine required to kill most of the intestinal pathogens studied under these conditions was 0.1 p.p.m., with the greatest destruction of the organisms occurring within the first 15 seconds of exposure. The same amount of chlorine destroyed most of the pathogenic types of respiratory organisms tested.

In each group, however, there were individual strains which were more resistant to chlorine than the others, requiring more than 0.1 p.p.m. to accomplish their destruction. In the intestinal group of organisms, the most resistant type encountered was *B. coli*. In the group of respiratory origin, three strains of hemolytic streptococci, out of 24 strains tested, required larger quantities of free chlorine for their complete destruction. All the resistant strains of streptococci were killed by 0.25 p.p.m. in 15 to 30 seconds. It is probable that the apparently higher resistance of the streptococcic strains is due to the larger number of organisms used in order to secure consistent growths.

From the standpoint of resistance to chlorine, *B. coli* stands out among the organisms tested as the most suitable for use as an index of the effectiveness of chlorine disinfection. The requisites of such an index organism are: (1) that it be as resistant as, or somewhat more resistant to, free chlorine than the pathogenic organisms which are to be destroyed; (2) that it grow readily on simple media; (3) that it be readily recognizable by simple routine tests. From the standpoint of availability, rapidity of growth, and ready detection, *B. coli* offers superior advantages as an index organism, and it is our feeling that its consistent absence in a menstruum after chlorine disinfection is valuable evidence of the destruction of the pathogens here studied.

On the whole, the experiments appear to furnish a satisfactory theoretical basis for the current practice of relying on the consistent destruction of *B. coli* in water as a criterion of effective chlorination, and that they may also justify a more general application of the same criterion to other type phases of chlorine disinfection now being developed, such as the washing of milk bottles and equipment and the washing of dishes and eating utensils.

A Sickness Survey of Winchester, Mass.*

Part II: Communicable Disease

CLARENCE L. SCAMMAN, M.D., FELLOW A. P. H. A.

and

CARL R. DOERING, M.D.

Massachusetts Department of Public Health, Boston, Mass.

A DESCRIPTION of the manner in which the survey was conducted, together with a short review of the demography of Winchester, was included in Part I.¹ Individuals under 20 years of age were questioned as to whether they had ever had any of the following diseases: measles, whooping cough, chicken pox, mumps, scarlet fever, German measles and diphtheria. They were also questioned as to the age and year when they had the disease, whether a doctor was employed, and whether they had had a second attack of the same disease.

Through the courtesy of S. J. Crumbine, M.D., of the American Child Health Association, unpublished data in connection with a similar survey in Gardner, Mass., covering the diseases scarlet fever, diphtheria and measles, are included in this report. Available data from other similar studies^{2,3,4,5} are included for comparison with those of Winchester and Gardner.

The number of persons (under 20 years of age) surveyed in Winchester was 3,365; in Gardner, 3,305; in Collins's report, 31,353; in London, 8,786; in Shelburne-Buckland, 394; in Brazil about 500, and in Baltimore about 5,000.

From the collected data, the percentage of individuals at different ages who suffered an attack of the specified diseases at some time during their lifetime was computed and compared with similar percentages from the other studies cited.

In Winchester approximately 80 per cent of the population under 20 years of age was surveyed; in Gardner the percentage was about 45. We feel that in both Winchester and Gardner a random sample of the age distribution of the population under 20 was approximated.

If the percentages from the different studies are plotted and smoothed, the shapes of the resulting curves vary. The curves for the

* The first of the series of studies, *Part I: General Morbidity*, by Herbert L. Lombard, M.D., M.P.H., was published in the September, 1928, issue of the AMERICAN JOURNAL OF PUBLIC HEALTH AND THE NATION'S HEALTH. Parts II and III are somewhat shortened. Reprints including full detailed material may be obtained from the authors.

seven diseases fall roughly into two groups. The one group including chicken pox, measles and whooping cough shows a sharp rise in the percentage of those attacked from 0 to about 10 years of age. The other group including diphtheria, scarlet fever and German measles shows a gradual increase in the percentages from 0 to about 20 years of age. The curve of mumps falls between the curves of the two groups mentioned, but more nearly approaches the curve of the first group.

These facts coincide with what is generally known in regard to the higher rate of infectivity in diseases like chicken pox and measles, as compared with a lower rate of infectivity for diphtheria and scarlet fever, based on clinical evidence.

The curve of any of these diseases would be affected by a falling incidence of the specific disease, whatever its cause. This applies in particular to diphtheria in Gardner, where there was a definite outbreak in 1917 with a decline since, and no cases reported in the last 2 years.

Chicken Pox—Slightly more than 50 per cent of the people have had chicken pox by the time they reach their 20th birthday. This disease is somewhat like measles. It attacks the population quickly and reaches its saturation point at about age 10.

Measles—By the time individuals reach the age of 20, roughly 90 per cent have had measles. There is some evidence that above the age of 10 both the individual questioned and his parents have forgotten whether the child concerned has had the disease. This is true in Gardner where the percentages decrease slightly but constantly from age 10 to 20. Although in Gardner the figures show that about 90 per cent of the population surveyed had the disease by their 10th birthday, for the total populations included in the study this is true of approximately 80 per cent.

Whooping Cough—By the time individuals reach age 20, from 60 to 75 per cent have had this disease. The percentage for Baltimore (43) is low for some reason.

Mumps—The incidence of this disease, except in Baltimore where the percentage is unusually low (24), varies from about 40 to 60 per cent at age 20.

Diphtheria—Making a rough allowance for variation due to small numbers, the percentages at age 20 in the studies cited vary from 3 to about 15. In Massachusetts, unpublished figures show that the morbidity and mortality from this disease vary with the size of the community, while in Shelburne, Winchester and Gardner a somewhat similar variation occurs. Shelburne, the smallest, is distinctly a rural

community. Although the population density of Winchester, the next larger, is somewhat higher than that of Gardner, the largest, Winchester is much more distinctly a residential community than is Gardner.

Scarlet Fever—Individuals who have had this disease by the time they reach the age of 20 vary in their percentages from 2 to 31.

German Measles—The incidence of this disease varies from 12 to about 23 per cent in the populations studied.

From the London, Winchester and Gardner figures at age 10 these percentages for the specified diseases are estimated as follows: chicken pox, 50; measles, 80; whooping cough, 65; mumps, 45; diphtheria, 5; scarlet fever, 10; German measles, 10. Of the two sets of percentages offered, we are inclined to believe that the percentages given at age 10 are more reliable than at age 20.

Secondary Cases—Table I shows the percentage of persons who had two independent attacks of the same disease. We are not satisfied that they are an accurate estimate of recurrent attacks.

TABLE I
PERCENTAGE OF INDIVIDUALS HAVING HAD ONE ATTACK OF SPECIFIED
DISEASE WHO HAD A SUBSEQUENT ATTACK

Disease	Winchester Per Cent	Gardner Per Cent
Measles	1.9	1.3
German Measles	2.4	—
Chicken Pox	0.3	—
Whooping Cough	0.4	—
Mumps	0.1	—
Diphtheria	1.1	0.6
Scarlet Fever	0.0	2.5

Number Employing Physicians—Table II shows the percentage of cases in which a physician was employed. The percentages were higher in Winchester than in Hagerstown or Gardner for most of the diseases, and may be due to a better economic status of the population

TABLE II
NUMBER EMPLOYING A DOCTOR

Disease	HAGERSTOWN		WINCHESTER		GARDNER	
	Cases	Per Cent of Total Having Disease	Cases	Per Cent of Total Having Disease	Cases	Per Cent of Total Having Disease
Measles	364	64.1	1518	76.8	1253	55.1
Diphtheria	44	97.8	90	91.0	151	96.2
Scarlet Fever	33	97.1	247	91.5	248	87.4
Whooping Cough	183	48.8	1319	74.4	*	*
Chicken Pox	105	45.2	1127	78.2	*	*
Mumps	3	33.3	666	74.8	*	*
German Measles	7	38.9	191	77.6	*	*

* Information not available.

in Winchester. A study of cases where practitioners other than physicians were employed in Winchester showed 4 per cent in scarlet fever, 2 per cent in diphtheria, 1 per cent in whooping cough, about 1 per cent in measles and 1 per cent in chicken pox.

Reporting of Diseases—Table III shows the percentage of reported cases for the three diseases in Gardner, for seven diseases in Shelburne and Winchester and for five in Hagerstown. The Gardner figures as well as the Winchester figures were obtained by taking the ratio or reported cases to the estimated number of cases based upon those found in the survey. It is worth noting that the figures show that with few exceptions scarlet fever and diphtheria are better reported than the other diseases.

Of all the percentages quoted, we are inclined to feel that the Hagerstown estimates are the most reliable.

* 1919-1926.

† 1917-1926.

‡ Dec. 1, 1921-Mar. 31, 1924.

SUMMARY

1. The seven diseases fall roughly into two groups. One group includes chicken pox, measles, and whooping cough, which shows a sharp rise in the percentages of those attacked from 0 to about age 10. The other group includes diphtheria, scarlet fever, and German measles, which shows a gradual increase in the percentages attacked from 0 to about age 20. The rise in the percentages of those attacked by mumps is more nearly like that in the first group.

2. At age 20, from the London, Winchester and Gardner figures, the percentage of individuals who had had the following diseases was roughly: chicken pox, 55; measles, 90; whooping cough, 70; mumps, 50; diphtheria, 15; scarlet fever, 20; German measles, 15.

3. At age 10 these percentages for the specified diseases were estimated as follows: chicken pox, 50; measles, 80; whooping cough, 65; mumps, 45; diphtheria, 5; scarlet fever, 10; German measles, 10.

4. Doctors attended in Hagerstown, Winchester, and Gardner from 87 to 98 per cent of the cases of diphtheria and scarlet fever and from 55 to 77 per cent of the cases of measles. In Winchester they

attended about 75 per cent of all the others of the seven diseases, and in Hagerstown from 33 to 49 per cent.

5. Scarlet fever and diphtheria are generally better reported than the other diseases.

Part III: Physical Defects of School Children

FREDRIKA MOORE, M.D., and ANGELINE HAMBLÉN

*Pediatrician and Statistician, Massachusetts Department of Public Health,
Boston, Mass.*

WINCHESTER, through an interested school committee and an unusually well-informed superintendent, was one of the first towns in the state to initiate a broad school health program. The school physician, whose standards are excellent, gives a "stripped to the waist" examination to every child from kindergarten through high school; he devotes an average of 2 hours a day to school work. A woman physician examines the junior high and high school girls. A nurse is employed full time in the schools. Health education is carried on by the teaching staff. Of the 8 school buildings, 5 have been built within the last few years.

Physical examinations of all the children were made in the fall by the school physician. In June before school closed the physician making the survey checked every child to note the defects which had been corrected during the winter. All the necessary records in this connection were collected, coded and studied. Fifteen hundred and thirty-five children were studied. Those whose defects were corrected were not counted as defective in the tables on absence.

A record of absences with duration and cause, for all children from kindergarten through junior high school, was kept through the school year 1926-1927 by the teachers.

DISCUSSION OF RESULTS

Defects and Sex—No association was found between sex and defects or between sex and the frequency of defects. Two hundred and eighty-one, or 36 per cent of 772 boys examined, had no defects noted;

283, or 37 per cent of 763 girls examined, had no defects noted; 38 per cent of both boys and girls had more than one defect.

Defects and Economic Standing—The children from the less privileged group, namely, the Noonan and Lincoln schools, showed a greater percentage of every defect than those from the more privileged, or the Mystic and Wyman schools. Figures from two schools having mixed groups were not included. In the schools included, the racial groups were practically pure. The number of corrections was proportionately greater in the Mystic and Wyman than in the Noonan and Lincoln schools. Out of a total of 834 defects in the first-named schools, 423 (51 per cent) were corrected. In the other schools out of 1,203 defects, 270 (22 per cent) were corrected.

TABLE I

PER CENT OF THOSE EXAMINED WHO SHOWED DEFECT, BY SCHOOLS

	Privileged Group			Less Privileged Group		
	Mystic Per Cent	Wyman Per Cent	Total Per Cent	Noonan Per Cent	Lincoln Per Cent	Total Per Cent
Nutrition	5	11	8	7	13	10
Posture	22	11	15	25	19	22
Tonsils	12	8	9	30	27	28
Adenoids	12	8	10	30	27	28
Teeth	12	9	10	47	49	48
Heart	9	6	7	10	15	12½
Eyes	32	18	24	38	35	36½

The Lincoln School showed a significantly larger number of defective teeth, tonsils, adenoids, and hearts; the Noonan a significantly larger number of defective teeth, tonsils and adenoids.

Correlation of Defects—The figures showed a positive correlation between defects of teeth and eyes, teeth and posture, teeth and tonsils, and teeth and adenoids, posture and nutrition, tonsils and adenoids, and tonsils and heart. This indicates that if a child has one defect he is likely to have other defects, and that there probably exists some fundamental condition underlying all his defects. The correction of the defects removes the inconvenience caused by the defect, but may probably have no effect upon the underlying conditions causing the defects.

TABLE II

NUMBER HAVING CERTAIN COMBINATIONS OF DEFECTS

	Eyes	Posture	Tonsils	Adenoids	Nutrition	Heart
Teeth	127 (100*)	116 (84)	122 (68)	117 (68)	57 (48)	50 (36)
Eyes		86 (81)	81 (65)	77 (65)	43 (46)	33 (35)
Posture			66 (55)	67 (55)	123 (39)	36 (29)
Tonsils				244 (44)	32 (31)	38 (23)
Adenoids					28 (31)	36 (24)
Nutrition						20 (17)

* Number expected according to the theory of independence.

Defects and Grade—Defects of nutrition and posture tended to develop with advancement in grade while defects of teeth and eyes were corrected. In the first grade the percentage of defective eyes was more than twice that found in the 7th and 8th grades and the percentage of defective teeth almost three times that in the 7th and 8th grades. The eye test was that given by teachers using the E chart, and was therefore very crude. The same test, however, was used for all children, and therefore the possibility of error was the same for all.

TABLE III

PER CENT OF THOSE EXAMINED WHO SHOWED DEFECTS IN GRADE

Defect	1st Grade Per Cent	2d-6th Grade Per Cent	7th-8th Grade Per Cent
Nutrition	5	11	23
Posture	18	19	33
Teeth	41	34	14
Tonsils	22	18	14
Heart	8	9	12
Eyes	51	26	25

Defects and Retardation—The first grade was the one most frequently repeated. The repeaters showed a higher percentage of defects than the non-repeaters, the percentage of repeaters showing defects of posture and teeth being significantly greater.

TABLE IV

PER CENT REPEATING EACH GRADE

No. of Children in Grade	Grade	Per Cent Repeating
1361	1st	10
1182	2d	5
1002	3d	5
805	4th	5
628	5th	7
473	6th	4
308	7th	1
148	8th	3

TABLE V

PER CENT OF THOSE FOUND TO HAVE DEFECTS AMONG REPEATERS' AND OTHERS

Defect	Repeaters Per Cent	Others Per Cent
Nutrition	15	12
Posture	31	19
Teeth	37	23
Tonsils	22	17
Heart	12	9
Eyes	31	29

Further study only will show whether the conclusions based on these figures are sound. So many other factors also enter into retardation that careful investigation is necessary to determine the

relative importance of each. This is particularly true in the 1st grade where children are entering a new environment and are obliged to adapt themselves to hitherto unknown conditions. The mental defectives are weeded out from grade to grade, which naturally lessens the number of retarded children in the upper grades. Language difficulties may be a cause of retardation.

Other interesting questions are raised by the study. Is there a real correlation between posture and retardation? Does the attitude of mind causing the failure also cause the poor posture or does the physical condition underly the failure? Are the findings in Table VI of sufficient importance to warrant further study?

TABLE VI

ALL CHILDREN IN PRIMARY OR ELEMENTARY GRADES WHO HAVE REPEATED
OR ARE TO REPEAT 1ST GRADE

Three Schools—(Not Giving I. Q.)

CAUSES OF RETARDATION AS GIVEN BY TEACHERS

1. No cause—immaturity—"backwardness"	52
(Of these 23 were Italians)	
2. Sickness	13
3. Needed glasses	2
4. Frequent absence	3
5. Deficiency in reading	6
6. Other reasons	8

Total repeating 1st grade	84

Two Schools—(Keeping I. Q. as Obtained in Group Tests)

CAUSES OF RETARDATION AS GIVEN BY TEACHERS

1. No cause—"backwardness"	24
I. Q. not given	5
I. Q. from 76-87	7
I. Q. from 90-100	5
I. Q. from 100-117	7
2. Sickness	4
3. Frequent absence	1
4. Needed glasses	1
5. Other reasons	2
<hr/>	
Total repeating 1st grade	32

Defects and Absence—The figures did not show that defects of nutrition, teeth, tonsils, heart, or eyes were more common among children who were absent from school. This included absence from any cause.

The median number of days absent of those with normal nutrition was 7.0, with defects of nutrition 5.6; with normal teeth 7.3, with defective teeth 5.4; with normal tonsils 6.8, with defective tonsils 6.2; with normal heart 6.9, with defects of heart 5.6; with normal eyes 5.7, with defective eyes 7.2..

TABLE VII
TOTAL ABSENCE

Cause of absence	Days Absence
Colds *	6,415
Other communicable diseases	1,816
Diseases of digestive tract	503
Sickness other than above or kind not stated	2,584
Absence due to causes other than sickness	2,850
Total days of absence	14,168

* The term "cold" as used here is used in the ordinary meaning of the term among lay people.

CONCLUSIONS

1. There was no association between sex and defects or the frequency of defects.
2. Children in the less privileged group showed a greater number of defects with fewer corrections than those from the more privileged group.
3. Defects of nutrition and posture increased with advancement in grade, while defects of eyes and teeth were corrected.
4. The figures showed a correlation between defects of posture and teeth and retardation. But the study does not bring out all the factors.
5. The figures did not show any correlation between defects and absence from school for any cause.
6. These findings were obtained in a town with a mixed population where environmental conditions are excellent and where there is a good school health program.

Relief to the Hurricane Districts

A REPORT of the Red Cross relief operations in districts recently affected by the West Indies hurricane shows that the organization has been active in Florida, Porto Rico and the Virgin Islands. Relief was hurried to the stricken area immediately and a minimum fund for care of the suffering was estimated at \$5,000,000. In about a week an amount totaling \$1,369,000 was raised by state chapters throughout the country, except in South Dakota and Nebraska, where a fund campaign is being carried on to take care of the sufferers of recent tornadoes in those states.

It was estimated that 15,000 families were made homeless in the entire area, but this report probably did not completely cover the Lake Okeechobee region. Food, clothing, camp and tent equipment were hastened to the stricken areas.

The Florida State Board of Health is in charge of all sanitary activities, and reports that rather favorable conditions prevail along the eastern coast. West Palm Beach reports a good water supply and is shipping water to points outside the city. All milk is being distributed from Miami. On the other hand the sanitary conditions around Lake Okeechobee have been serious due to the unburied bodies of people and animals and the continued flooded condition of the land. The State Board of Health was assisted by the Red Cross and the National Guard in disposing of the dead and cleaning up the flooded regions. Public health nurses from various districts of Florida and Georgia assisted the contingent of Red Cross nurses detailed to the relief work. Typhoid serum has been offered to the Florida State Board of Health and to the Red Cross. In the Virgin Islands the sanitary situation is well in hand, but in Porto Rico the situation is more serious.

Vision Survey Among a Group of Pupils of Syracuse Schools

HARRY H. LEVY, M.D.

Syracuse, N. Y.

THE care of the vision of the school children is a responsibility that must be assumed by school authorities as well as by the parents. Many times the fact that a child has poor vision is not discovered until he enters school.

The age at which the vision of school children should be tested, and the methods which should be used, have been matters of considerable discussion. Whether the school physician in his routine examination is able to find the cases of eye defects requiring the attention of an oculist has also been questioned. In our effort to determine these points and to make studies of other factors bearing on visual comfort, a staff was specially formed and equipped to make a study in Syracuse schools. Schools were chosen in which there were children of varied nationalities and economic home conditions.

The study was conducted under the direction of the author, with the assistance of one physician full-time and one part-time. The nurse located in the school in which the work was being done also assisted. A clerk recorded findings. The study was begun October 15, 1926, and completed May 31, 1927.

A Snellen test card at a distance of 20 feet was used. This was illuminated by direct light greater than 10 foot-candle power. This test was later supplemented by a Snellen test card mounted on a board, to the upper edge of which was attached an electric fixture similar to that used on desk lamps. A 50 candle power frosted bulb threw the desired amount of illumination down upon the chart. This apparatus, which proved most satisfactory, was designed in the Department of Health Supervision of School Children, and was assembled in the vocational department of one of the schools.

In addition to the Snellen test card an Ives acuity apparatus* was used. The illumination is a part of the apparatus and therefore of constant intensity. This apparatus measures vision numerically in tenths, with "one" equivalent to normal, or approximately 20/20 on the Snellen test card. However, after examining 1,499 pupils with

* Loaned by the Bausch & Lomb Optical Company, Rochester, N. Y.

the Ives acuity apparatus and finding that the results obtained corresponded very closely with the results obtained from the use of the Snellen test card, the use of the Ives acuity apparatus was discontinued as unsatisfactory for school work for the following reasons:

1. The test is entirely subjective. For this reason it is necessary to depend upon the reply of the pupil in taking the vision. In the second year coöperation was unsatisfactory in some cases and below the second year coöperation could not be expected.

2. The instrument is so large it is not easily transported.

3. The instrument is very expensive and therefore could not be a part of the equipment of each school.

The Snellen test card, mounted on a board and illuminated with a 50 candle power bulb, is much more satisfactory than the Ives acuity apparatus for use in the schools for the following reasons:

1. The Snellen test card is objective and what the pupil can read is visible to the examiner.

2. The Snellen test card has the advantage of being interchangeable for use in examining pupils who do not know the letters. In this instance the illiterate E chart has proved very useful, especially in the kindergarten grades.

The vision of each eye of the pupil was determined in the examination. Where the pupil was wearing glasses the vision was taken with and without glasses. The test was made first with the Snellen test card. In the first 1,499 pupils examined, the Ives acuity apparatus was used in addition to the test with the Snellen test card.

Following the vision test the lids were everted and inspected, pupillary reflexes tested to light, the cornea examined, muscle balance tested as to relationship of the two eyes, and an examination of the interior or fundus of the eyeball was made. Through this examination it was learned whether it was some pathological condition or abnormality of the eyeball itself which interfered with vision or whether the difficulty was due to refractive error, such as far-sightedness, near-sightedness, astigmatism or a combination of any of these.

A history chart, filled in by the pupil examined, presented a record of symptoms and a history of previous diseases, or conditions that might affect vision. The record furnished by this chart and the result of the vision test were correlated in determining the further treatment of each case.

The standard of poor vision will be understood to be a vision of 20/40 or less. Pupils with a vision of 20/40 or less, and pupils with a vision of 20/30 or better who presented symptoms of asthenopia, were referred for further investigation. Since we find cases where an individual has a vision of 20/30 and in which there is found a refractive error of small degree which would not account for the vision being less than 20/20, we designated 20/30 as the upper limit of normal. A

TABLE I

PUPILS WHOSE VISUAL ACUITY WAS DETERMINED AND NUMBER REFERRED FOR REFRACTION

School	Nationality	Economic Conditions	Number Enrolled	Pupils Examined	Pupils with Poor Vision	Percentage with Poor Vision	Pupils with Asthenopia	Percentage with Asthenopia	Total Number Referred for Refraction	Percentage Referred for Refraction
Brighton	American	Good	458	432	44	10.2	37	8.5	81	18.7
James Street	American (mixed)	Good	823	767	64	8.3	51	6.6	115	15.0

pupil with vision of 20/30 and with no symptoms was not routed for refraction. The cases which were routed for refraction and further examination were given the card used in the schools advising parents to consult the family physician or an oculist.

Of the 4,060 pupils examined 3,910 were cases of hyperopia; 142 were cases of myopia, and 8 were cases of mixed astigmatism which is a type of myopia. Among the 4,060 pupils examined 63, or 1.5 per cent, were afflicted with strabismus or cross-eyes. Of these 63 cases, 26 were referred for refraction, 3 of whom were already wearing glasses.

Of the total number of 4,060 pupils examined, the visual acuity of 39 could not be determined because of lack of coöperation. Among the 4,021 pupils were 11 who had poor vision because of disease to some part of the eyeball and 1 pupil who had lost an eye. There were 10 cases of defective color vision. It is possible that if these cases had been further investigated, it might have been found due to color ignorance rather than to color blindness.

Since poor vision alone is not the only reason for the need of re-

TABLE II

NUMBER REFERRED FOR REFRACTION—BY SCHOOL AND SEX

School	Pupils Examined	Boys Examined	Boys Referred for Re- fraction	Percentage Boys Re- ferred for Refraction	Girls Examined	Girls Referred for Re- fraction	Percentage Girls Re- ferred for Refraction

fraction and the use of glasses, a search was made for symptoms of weak vision or asthenopia brought on by unusual use of the eyes, even where the vision may have been normal. Table I shows, by schools, the number of pupils whose visual acuity was determined and the number referred for refraction and Table II shows, by school and sex, the number referred for refraction. These figures indicate that the percentage of girls referred for refraction is slightly greater than that of boys, 17.6 as compared with 15 per cent. Table III shows the number at the various ages referred for refraction. These figures, as would be expected, show in the older age groups a gradually increasing percentage of children in need of refraction. Table IV shows the number referred for refraction in the various grades.

To aid in determining whether scholarship is affected by vision, a chart termed "psychological chart" was made by the teacher for each pupil. This chart gave the number of failures, if any; the scholarship rating; the intelligence or mental ability; industry or desire of the pupil to work; and the intelligence quotient of the pupil.

Scholastic records were available in the cases of 3,894 pupils. Of this number, 1,207, or 31 per cent, failed at least once. There were 2,207 pupil failures, or an average of 1.8 failures per pupil who failed. There were 2,035 boys, of whom 713, or 35 per cent, failed; and 1,859 girls, of whom 494, or 26.6 per cent, had failed at least once.

In reviewing the records of failures in the schools and the number of failures per pupil who failed, we find the highest rate occurring in the Jefferson School, where the parents of the pupils are mostly foreigners and the economic conditions are only fair. Under these circumstances there is usually little opportunity for assistance at home.

Girls with defective vision	57.1	—	7.1	30.9	40.4	36.6	32.7	35.7	30.7	40.7	20.	34.2
Total Registration	77.7	—	15.66	27.6	34.3	34.	37.35	37.5	35.6	34.	34.3	31.

Of the 655 pupils referred for refraction (see Table III), scholarship ratings were available in 638 cases. These are shown in Table VI.

TABLE VI

SCHOLARSHIP RATING AMONG PUPILS WITH DEFECTIVE VISION

		Rating		Rating	
		Poor or Fair		Good or Excellent	
Number Recorded		Number	Per Cent	Number	Per Cent
Total	638	289	45.3	349	54.7
Boys	307	144	46.9	163	53.1
Girls	331	145	43.8	186	56.2

It would appear from the figures and from observations, that the greatest factor influencing scholarship among pupils is the intelligence of the pupil and his desire to work, rather than the fact that he has poor vision. The records indicate that if the pupil is willing and anxious to learn and has the ability to retain knowledge, even though his vision may be poor, his scholarship is of the average or better.

By means of the foot-candle meter the amount of illumination in the schoolrooms was measured, and with the exception of one school it was found to be of sufficient degree to meet the standard requirements of 5 foot-candles. However, we do not believe this is sufficient to provide proper illumination for the pupils seated farthest from the windows even on bright days. In the newer schools it was found that the proportion of window space to the size of the rooms and the placing of the seats to avoid shadows were excellent. Despite this, however, on dark days when artificial light was required, illumination in the rooms was poor. It was impossible to learn the conditions under which the pupil must work in preparing his lessons at home.

An examination of the books in the classrooms showed that with few exceptions glazed paper was used. There is no paper so troublesome to vision and visual effort. In many cases the print was entirely too small and very little attention had been given to spacing.

Another source of great annoyance was the reflection from polished desk surfaces. It would seem that the comfort of the pupil would be increased and visual effort decreased if desk surfaces were finished dull.

FIGURE I—PERCENTAGE OF PUPILS EXAMINED REFERRED FOR REFRACTION—BY AGES

It would also aid in decreasing visual effort if the blackboards were given a dull finish. It is suggested that, until blackboards are finished with a dull surface, soft chalk be used.

SUMMARY

Of the 4,021 pupils whose visual acuity was determined, 1,499 were tested with both the Snellen test card and the Ives visual acuity apparatus. The results corresponded most favorably and justified the continued use of the Snellen test card because of its adaptability to all conditions, and the discontinuance of the Ives visual acuity apparatus because of the inconvenience involved.

Of the 4,021 pupils whose visual acuity was determined, 382, or 9.5 per cent, were referred for refraction because of poor vision and 273, or 6.7 per cent, because of asthenopia. A total of 655, or 16.3 per cent, were referred for refraction.

FIGURE II—PERCENTAGE OF REGISTRATION REFERRED FOR REFRACTION—BY GRADES

FIGURE III—PERCENTAGE OF FAILURES AMONG PUPILS WITH NORMAL VISION AND DEFECTIVE VISION—BY SCHOOLS

There is a steadily increasing number with defective vision from the early years with a condition of progressive myopia.

The general consensus of opinion has been that scholarship is affected by poor vision. The higher percentage of failures among pupils with poor vision would bear out this belief (Figure III). The fact that the higher percentage of failures occurs among pupils of both sexes with poor vision would tend to strengthen this assumption (Figure IV).

However, a further study of the relationship between failures and defective vision shows the higher percentage of failures to have occurred among the boys of whom there were but 15 per cent referred for refraction as compared with 17.6 among the girls (Figure V).

The highest percentage of pupils of both sexes was referred for refraction at Seymour School (Figure VI). The highest percentage of failures among both sexes occurred in Jefferson School where the nationality is Italian and the home conditions are poor.

Among the pupils referred for refraction the higher percentage occurred among those with good or excellent scholarship.

We believe the charts shown present a comparable study of the relationship between defective vision and scholarship and justify our conclusions that other factors influence scholarship as much or more than poor vision and asthenopia, and that poor scholarship is due more to lack of mental ability than to poor vision or asthenopia.

As a result of our study of the relationship of light to the comfort of the school child, it was found that even in the most modern schools conditions are still far from perfect. Bright days are the exception rather than the general rule in Syracuse and we believe that additional indirect lighting should be added to the direct lighting of the rooms.

FIGURE IV

The study cannot be considered complete until the results of our examinations are checked a year later. At that time the pupils who were referred for refraction will have had the benefit of the examination and correction. It will also be an opportunity to learn just how many cases have improved in scholarship and industry as a result of this correction.

FIGURE V—PERCENTAGE OF FAILURES AMONG PUPILS REFERRED FOR REFRACTION BY SEX AND SCHOOL

FIGURE VI—PERCENTAGE REFERRED FOR RETRACTION—BY SEX AND SCHOOL

RECOMMENDATIONS

1. That the examination of vision be emphasized as a part of the routine physical examinations in the schools by the school medical supervisor.
2. That besides taking vision at the regular intervals of physical examinations vision also be taken once a year of all the other pupils.
3. That the school nurse be taught how to take and record vision tests.
4. That the apparatus for making vision tests be made standard in all the schools in Syracuse, and that this apparatus be the Snellen test card, mounted according to design in the Department of Health Supervision of School Children and as assembled in the vocational department of the schools.
5. That conditions of lighting the schoolrooms be investigated with a view to improving them.
6. That blackboards and desk tops be finished with dull surfaces to prevent eye strain.
7. That the school textbooks be investigated from the standpoint of visual effort.

PULLING TOGETHER FOR CHILD HEALTH

A NEW feature of the Annual Meeting in Chicago this year is the occurrence at the same time and place of the annual meeting of the American Child Health Association. Community of interest has led our Child Hygiene Section and this large voluntary association to join hands in the presentation of programs of common appeal. In one or more instances also these sessions are participated in by the Sections of Public Health Nursing, Health Officers and Public Health Education. This action lends strength and richness to the program and to the discussions.

Neither the identity nor independence of thought and action of the participating groups is interfered with by this step and, on the positive side, understanding and singleness of purpose are greatly enhanced.

Great strides have been made in child hygiene in the last 20 years. In fact, the child hygiene program might be called a product of the 20th century. Proceeding along individual lines, divergence in methods and procedures in different communities has been inevitable. The great problem facing the child health worker is so to unravel the connecting threads of cause and effect in order to enable him to identify the activities which are effectual and to distinguish them from efforts that are imposing and theoretically justifiable, but whose results are relatively inconsequential.

These joint programs give a wide array of contributions from leaders in the field of maternal and child hygiene. So accustomed have we become to declining death rates, such as in tuberculosis, diphtheria, and infant mortality, that the failure of a specific cause of death to conform to this tendency challenges our attention. One of the factors that has been particularly difficult to overcome is maternal deaths.

An entire session is given over to this subject. Here the obstetrician, the gynecologist, the official and unofficial health worker, have the opportunity to pool their experiences and seek a strengthened union of effort. Infant hygiene, preschool health supervision, medical, dental and nursing service, and educational methods in health are topics of other sessions which will be discussed from many angles. Out of this exchange of ideas are bound to arise clarification of thought and renewed incentive to productive effort.

A perusal of the preliminary program of the joint meetings discloses that there is an increasing tendency toward critical self-analysis and research—research into the fundamentals. There is also evident an earnest desire to perfect organization and eliminate waste motion. Further, it is apparent that a finer discrimination is being exercised as to what findings from the bacteriological and the social laboratory are suitable for wide application in health practice.

PERMANENCY OF TENURE

AMONG the oldest interests of the American Public Health Association is the attainment of permanency of administrative tenure. It has long been recognized that with frequent shifting of administrative heads continuity of program and satisfactory service for local and state health work are practically impossible. The development of effective community health service depends upon sound policies and practices, well established and accepted generally by the public. Time and steadfastness of purpose both are requisites of community education. It is a matter of general comment that transient tenure, with its attendant political complications and vacillating policies, is the most significant difference between health administration here, in the United States, and that in Europe.

There are enough splendid examples of great accomplishments by health officers who have directed state or local services for continuous periods of twenty-five years or more, to prove the applicability of the principle under our form of government; yet many cities and states continue the wasteful and inefficient practice of changing health officers with every change of general administration.

A committee of the Association, appointed within the year to study and deal with this question, will hold an open conference the first day of the Annual Meeting at Chicago to consider the many aspects of the problem and to receive suggestions as to how such a committee may effectively serve the members of the Association.

This is a question vitally affecting every member of the Association, and to the solution of which all should contribute thought and influence. Your active support of the Committee on the Permanency of Tenure is a necessity.

APPRAISAL OF ADMINISTRATIVE PRACTICE

FOR many years health officers had no special standard by which to judge the efficacy of their work. It is true that conferences were often held, and our own Association, for many years composed almost entirely of health officers, held discussions and doubtless all taking part in them were benefited by the experiences of others. Nevertheless there was no uniform practice and no standard of appraisal, a lack felt by health officers themselves perhaps more keenly than others, though recognized by all interested in the betterment of health administrative work.

Various schemes were devised for the measurement of certain activities, the first one being a score card for dairies, devised about 1903 for use in the District of Columbia. This was soon followed by others, mostly for the grading of dairies and milk supplies, but the first form which covered a wide range of public health work was put out by Dr. Chapin in 1914. Finally in 1920, the American Public Health Association appointed its Committee on Municipal Health Department Practice, and in 1923 the first draft of the Appraisal Form was prepared. In 1925, the Appraisal Form was issued by our Association for experimental use by the health officers of cities. This form with slight modifications has had extensive trial, one of the most notable being the Health Survey of 86 Cities, conducted by the American Child Health Association.

Up to the present, the Appraisal Form has been employed in some two hundred cities varying in size from fifteen thousand up to one and a quarter million inhabitants, and distributed over a large part of the country. These, as well as many other facts concerning the Appraisal Form, have been published from time to time, and are now collected in one volume which is reviewed in this issue of our JOURNAL.¹

Doubtless, the great majority of health officers have followed the development of this method of appraisal, but all will welcome the searching criticism which has been made of its validity, and everyone will be glad to know that we now have an objective measure of the value of public health practices.

The use of the Appraisal Form has passed beyond the experimental stage. Its value has been proved both in practice and by scientific

analysis. Its wider use can be recommended without hesitation. We may also state with assurance that the revision contemplated for the present year will further increase its practical value and confirm the validity of the fundamental principles involved.

1. *The Validity of the Appraisal Form as a Measure of Administrative Health Practice.* (See p. 1324.)

A NEW VIEW OF SMOKING

ONE of the standard gags perpetrated at meetings of scientific men is calling attention to the lack of ventilation and other breaches of sanitary law which may almost always be observed. There is generally truth in the statements made, and frequently the fault lies as much with the building as with the sanitarians who are discussing the welfare of the human race and what should be done or left undone to prolong life. Tobacco smoking in meetings has always, as far as the observations of the writer go, passed unnoticed. There are doubtless a number of persons who object to tobacco smoke and who would prefer to have smoking prohibited, since it is disagreeable to many persons, irritates the throats of others, and sometimes is so thick as to interfere with lantern slide demonstrations, which are bad enough at best, since they usually involve almost complete blocking of ventilation. However, smoking is usually passed by in silence, whatever may be the opinions of certain members of the audience, for several reasons, the chief one being the fear of being considered a crank, while the habit is so general that one feels hopeless of making any change.

These considerations make an address recently given in England particularly noticeable. Before the Southern Branch of the Society of Medical Officers of Health, Dr. Druitt was speaking on smoke abatement from the standpoint of health. A large part of his time was devoted to tobacco smoke and the pollution of the atmosphere produced by it.

While acknowledging the absence of statistics to prove his point, he held that such pollution was at least on "speaking terms" with several serious causes of mortality, among which he mentioned tuberculosis, pneumonia and bronchitis. He further quoted observations indicating not only that the wives of heavy smokers do not produce as many healthy children as those of nonsmokers, but also that the proportion of males is less.

Whatever doubt we may have of the correctness of the observations and the conclusions drawn therefrom, it is certainly inconsistent for health officers and sanitarians who are discussing problems of atmospheric pollution, ventilation, etc., to sit for hours in rooms filled

with tobacco smoke. Surely they, above all others, should set a good example.

The subject is one of particular interest at this time when our daily papers, even those published at universities, give pictures of society women, movie stars and even aviators, who select one brand or the other of cigarettes blindfolded, owing to its alleged superior qualities, and when singers give certificates for other brands because of the soothing effect on the vocal cords, and when the tobacco habit is apparently becoming prevalent among women. That tobacco is a narcotic poison is a statement not disputed by anyone in authority. The late Sir William Osler called attention to the fact that a number of puzzling cases in women in England which were new to the average physician proved to be due to the increase of the smoking habit. The effects of tobacco on the heart, respiration, eyes and vocal cords have long been recognized.

"Scientific evidence is hardly needed to show that to some extent the person breathing a smoke-tainted atmosphere is liable to the same evils as the person who is smoking, for the experience of a non-smoker who has spent an evening in the atmosphere of a smoking concert is often that he sustains a disturbance of health similar to that sometimes complained of by the excessive smoker."¹

We do not believe this is a major point in sanitary advance, but it is certainly worth our while to consider the facts.

1. *Lancet*, Apr. 26, 1913, p. 1181.

ASSOCIATION NEWS

THE A. P. H. A. MEETING

THE scientific program for the 57th Annual Meeting at Chicago this month contains several important symposia. Nearly all of the sessions of the Child Hygiene Section have been built around special topics such as: Maternal Mortality; Dental Hygiene; Efforts to Date to Define Objective Standards in Health Education.

Similarly, the Public Health Engineering Section program has symposia on the Sterilization of Milk Containers and Equipment; a program on Financing Water Supply and Sewerage Projects; a symposium on the Disposal of Phenol Wastes; and one on Shellfish Sanitation. Many others than the engineers will be interested in the reports of the Schoolroom Ventilation Studies which have been carried on in various cities.

Following the successful session on Epidemiology last year, a program of 7 papers on this subject has been prepared for this year. A special session will be held on the subject of Cancer Control. This program is being arranged by the President of the Association and Dr. Charles Mayo.

The recent widespread interest in undulant fever has been recognized by the Laboratory Section, which will present 6 papers on this subject.

In response to the demands from many members of the Association who are active in rural areas, the Health Officers Section has provided a special program on Rural Health Practice.

The importance of accidents as a public health problem will be dealt with in the first session of the Vital Statistics Section.

The Public Health Education Section, continuing its popular luncheon sessions, has devoted two entire sessions to the

consideration of the desirable steps in planning a health education publicity program.

The Preliminary Program of the meeting, which was printed in the September issue of the JOURNAL, lists about 200 papers and reports. The list of authors represents a large proportion of the public health authorities in America.

EXHIBITS

The Tenth Annual Health Exhibit of the Association will be held as part of the 57th Annual Meeting. This exhibit is twice as large as any exhibit ever sponsored by the Association in previous years. The members of the Association and delegates to the meeting will find it most advantageous to visit this exhibit during the morning hours when it is restricted to them. It will be open to delegates from 9 A.M. to 1.30 P.M. and from 5.00 to 7.00 P.M. In the afternoon and evening the exhibit is open also to the public, closing at 10.30 P.M.

Nearly all of the exhibitors who have been with us in past years will also have displays at Chicago, with much new material to show. This year, too, there are a large number of new exhibitors offering a variety of services to the professional public health worker.

In addition to this exhibit, there is a scientific exhibit on the third floor, open to delegates only, and this will include the exhibit on Administrative Practice,* which was so successful last year.

A complete list of the administrative methods being exhibited and the cities or organizations exhibiting will be found on page 1289. Twenty-six separate exhibits are planned to cover the

* The exhibit on Administrative Practice which is a part of the Scientific Exhibit is made possible through the financial assistance of the John Hancock Life Insurance Company and the Milbank Memorial Fund.

fields of general health administration, child hygiene, communicable disease control and epidemiology, health education, organization of state and county health service, sanitation and roadside water supplies, public health demonstrations, Indian nursing service and accident prevention.

The purpose of the exhibit is to acquaint the health officer with new developments, or new ways of doing old jobs, and to present in concrete form information concerning these methods, which will enable the health officer to judge of its applicability to his own local community and organization.

The Committee on Administrative Practice which sponsors the administrative features of this exhibit will appreciate suggestions regarding subject matter and method of display.

If you are interested in spreading information about any phase of public health or public health activities, you are invited by the Public Health Education Section to visit frequently the Education-Publicity Headquarters.

Making statistics graphic, a new type of posters, the latest in diphtheria materials, annual reports, contest ideas, campaign outlines and materials, devices for getting attention and holding it, and examples of good publicity of various types will be features of the display.

The committee in charge will answer questions and offer consultation on health education problems and plans. The committee suggests that you bring along with you a supply of your business cards, with a number written on each one, and when you return home you will receive free copies of such selected items as you indicated you wish to have.

Associations holding related meetings with the A. P. H. A. have also planned special exhibits. The American Child Health Association has arranged an exhibit to interest those attending the meeting in its organization and program.

The important place which social hygiene should occupy in the public health program will be indicated by the exhibit which the American Social Hygiene Association will display at the meeting.

The display will include a new set of statistical charts which has been worked out by the Medical Division of the A. S. H. A., showing the relative prevalence of venereal diseases in the United States and Great Britain, with interesting figures on the influence of efforts to control these diseases. Some of the exhibit material on syphilis, gonorrhea in the male, and gonorrhea in the female which has been shown by the association at annual meetings of the American Medical Association also will be on view in Chicago.

In order that "he who runs may read" the A. S. H. A. will distribute at the exhibit booth small packets containing information about the purpose and scope of its program. Much interest has been evidenced in the reading lists, which are among the circulars included in these free envelopes.

Copies of the books and pamphlets on the control of venereal diseases, social hygiene legislation and sex education will be available for examination at this booth.

A copy of the association's film "Public Health Twins at Work," revised, with up-to-date statistics, will be shown with the films which the National Health Council is displaying at the conference. Information regarding other social hygiene films which the association distributes will be available at the exhibit booth. The attendants will be prepared to discuss any social hygiene problems with which sanitarians are confronted.

BOOK EXHIBIT

The seventh annual exhibit of new books on public health, arranged under the auspices of the Book Service of the Association, will be well worth several

visits. It will be found in Wall Exhibit D in the exhibit hall. More than 60 publishers are sending their newer books for the display aggregating 500 volumes. The Book Exhibit has been arranged for the entertainment and education of delegates, as well as to help those who desire to purchase the latest titles in preventive medicine, laboratory methods and findings, food, drugs and nutrition, mental hygiene, social hygiene, health books for children, etc. You are invited to spend as much time as you can at the Book Exhibit. There will be an experienced librarian in charge, who will be glad to answer your questions and advise you in the selection of the best and newest books.

RELATED MEETINGS OF A. P. H. A. IN
CHICAGO

This year 9 public health organizations will hold related meetings with the A. P. H. A. when it convenes at Chicago, October 15-19, for its 57th Annual Meeting.

The preliminary program published in the September issue of the JOURNAL announced the time and place of joint sessions and individual meetings of a few of the organizations scheduled.

In addition to these the following have announced their dates of meeting:

International Association of Dairy and Milk Inspectors (17th Annual Meeting), October 11, 12, 13, Hotel Stevens.

Association of Women in Public Health, Dinner Meeting, October 17, Hotel Stevens.

Conference of State Sanitary Engineers, October 13-15, Hotel Stevens.

State Laboratory Directors Association, October 15, 10.00 a.m. and 1.30 p.m., Luncheon Meeting, Hotel Stevens.

MEETING OF AMERICAN ASSOCIATION OF
SCHOOL PHYSICIANS
HOTEL STEVENS

Monday, October 15, 9:30 A.M.

Welcome Address. DR. ARNOLD H. KEGEL, Commissioner of Health, Chicago, Ill.

Standards for Medical Inspection and Health Service in Teacher Training Institutions (Report of Committee). DR. A. O. DEWESSE, Kent State Normal College, Kent, O.

Discussion. DR. GRACE S. WIGHTMAN, Illinois State Health Department.

Educational Qualifications for School Physicians. DR. HAVEN EMERSON, New York, N. Y.

Standard Forms and Methods in School Medical Inspection. DR. J. BRUCE MCCREARY, Pennsylvania State Health Department, Harrisburg, Pa.

When Should We Operate on Tonsils? DR. PORTER B. BROCKWAY, Toledo, O.

Open Air School Ventilation. DR. L. W. CHILDS, Cleveland, O.

One hour of each session will be devoted to brief reports by school physicians doing outstanding work.

2:00 P.M.

1. A Model School Medical Inspection Program.

(a) *In First Class Cities.* DR. JOHN A. CECONI, Boston, Mass.

(b) *In Second Class Cities.* DR. F. S. BURKE, Toronto, Ont.

(c) *In Third Class Cities.*

(d) *In Rural Communities.* DR. B. T. McDOWELL, Canandaigua, N. Y.

2. Mental Hygiene in Education. Suggestions to School Physicians. DR. CLINTON P. MCCORD, Albany, N. Y.

3. How Can the Nurse Best Assist the School Physician? HELEN F. MCCAFREY, R.N., Boston, Mass.

Dinner Session, 6:30 P.M.

Selection and Management of Cardio-pathic Cases. DR. SVEN LOKRANTZ, Los Angeles, Calif.

The Important Contributors to a School Health Program. CLAIR E. TURNER, Dr.P.H., Cambridge, Mass.

Medical Leadership in School Medical Inspection and Health Service. DR. HAVEN EMERSON, New York, N. Y.

DR. J. S. FULTON, MARYLAND'S HEALTH OFFICER, RESIGNS

Maryland's success in developing its public health program has been due to a great degree to the efforts of John Samuel Fulton, M.D., who, after 30 years' service, has resigned as health director of Maryland.

Dr. Fulton was born in Fremont, O., in 1859.

He was appointed State Health Officer of Maryland, September 17, 1896.

In 1898, Dr. Fulton secured the appointment of Dr. William H. Welch as a member of the State Board of Health, in which capacity he is still serving, and he was president of the board until the reorganization of the entire state government by the Governor of Maryland in 1922. Since January 1, 1923, when the reorganization became effective, Dr. Welch has been a member of the board of health and Dr. Fulton has been the director and chairman of the board.

As a result of legislation passed in 1904 requiring the registration of all living cases of tuberculosis, Maryland

was the first state to register cases of tuberculosis. Other states followed Maryland's example.

Following the enactment of this law, Dr. Fulton brought about the first tuberculosis exhibition held in Maryland in the spring of 1904. It was at this exhibition that a few leading persons interested in the subject of tuberculosis formed what proved to be the nucleus of the National Tuberculosis Association.

In 1906, Dr. Fulton was elected Secretary-General of the Sixth International Congress on Tuberculosis, which was held in Washington in 1908.

The committee, selected to make plans for the Fifteenth International Congress on Hygiene and Demography in Washington in 1912, named Dr. Fulton as its head.

Dr. Fulton was President of the Conference of State and Provincial Health Authorities of North America in 1905. During the World War he enlisted in the Medical Reserve Corps, U.S.A., and became Lieutenant-Colonel. He served full time at headquarters in Washington and also carried on the activities of the State Department of Health after office hours. He has been Professor in State Medicine at the University of Maryland Medical School and lecturer in the Johns Hopkins School of Hygiene and Public Health. He is a member of the American Association for the Advancement of Science, National Tuberculosis Association, Hygiene Reference Board of the Life Extension Society, Inc., Honorable Member of the Royal Hungarian Society and a Fellow of the Royal Institute of Public Health, Great Britain. He is a Fellow of the American Public Health Association.

No doubt one of the greatest tributes paid to him comes from his fellow workers for the last quarter of a century, expressed in a resolution made by the State Board of Health on receipt of his resignation last May from the directorship of the public health of Maryland.

JOHN SAMUEL FULTON, M.D.

Dr. Robert H. Riley, who was trained by Dr. Fulton, was appointed as his successor.

DR. C. O. SAPPINGTON APPOINTED BY NATIONAL SAFETY COUNCIL

C. O. Sappington, M.D., Dr.P.H., has been appointed Director of the Division of Industrial Health at the National Safety Council, Chicago, Ill. This division has just been created, and Dr. Sappington is the first director.

DR. J. H. SHRADER JOINS NATIONAL DAIRY PRODUCTS CORPORATION

J. H. Shrader, Ph.D., Director, Bureau of Chemistry and Food, Health Department, Baltimore, Md., has accepted the presidency of the Research Laboratories of the National Dairy Products Corporation, Inc. Dr. Shrader's resignation from the Baltimore Health Department became effective August 31. The new laboratories will be located in Baltimore and the work there will be

directed toward the improvement of dairy products. Dr. Shrader is Chairman of the Food, Drugs and Nutrition Section of the American Public Health Association.

DR. LINSLEY R. WILLIAMS LEAVES N. T. A.
DR. KENDALL EMERSON HIS SUCCESSOR

Linsley R. Williams, M.D., since 1922 Managing Director of the National Tuberculosis Association, has resigned, his resignation to take effect October 1. Because of the increasing pressure of work in the several professional and public health activities in which he is engaged Dr. Williams decided several months ago that as soon as his successor could be found he would leave the N. T. A.

Dr. Williams is director of the New York Academy of Medicine, president of the New York Tuberculosis and Health Association, and a trustee of Columbia University. He is a Fellow of the American Public Health Association. Since 1904 he has been a member of the Board of Managers of the New York Association for Improving the Condition of the Poor. Following his service during the World War as assistant division surgeon of the 80th Division, Dr. Williams was made director of the Rockefeller Tuberculosis Commission in France. In 1914, he retired from the practice of medicine to accept the appointment of deputy commissioner of the New York State Department of Health in which capacity he served until 1917. Dr. Williams has been connected with the Vanderbilt Clinic of the College of Physicians and Surgeons, Columbia University, for several years and has been associated with several sanatoria for tuberculous patients. He was also one of those responsible for the creation of the New York Milk Committee.

Dr. Kendall Emerson of Worcester, Mass., has been elected to succeed Dr. Williams as Managing Director of the

N. T. A. Dr. Emerson is a graduate of Amherst College and of Harvard University Medical School. He has been active in the national tuberculosis program for several years, having served consecutively as chairman of the Worcester, Mass., County Tuberculosis Association, director of the Massachusetts Tuberculosis League, president of the league and representative director of the N. T. A., becoming member of the executive committee of the association last year. During the World War Dr. Emerson served with the Royal Army Medical Corps and the U. S. Army Medical Corps, later going to Siberia for the Red Cross. For two years after the armistice he acted as deputy commissioner and director of the medical service for Europe in Paris under the direction of Robert F. Olds.

DR. M. M. SEYMOUR RESIGNS FROM
PROVINCIAL HEALTH POST

Maurice McDonald Seymour, M.D.C.M., D.P.H., LL.D., whose activities in the public health work of Canada for more than 20 years have brought him prominence among sanitarians in the United States and Canada, has resigned as Deputy Minister of Health of the Province of Saskatchewan. Dr. Seymour has reached the retirement age but he will be retained by the provincial government as adviser on health matters until November.

Dr. Seymour is a Fellow of the American Public Health Association and served as vice-president of the Association for one year. He has also served as president of the Canadian Public Health Association. With the establishment of the Department of Health of Saskatchewan in 1922, Dr. Seymour was appointed deputy minister, thus becoming a member of the Dominion Council of Health. In 1926 he was elected president of the Conference of State and Provincial Health Authorities of North America.

Dr. Seymour was chosen in 1923 to represent Canada on the Health Section of the League of Nations and with representatives of 18 other countries made a health survey of the United States, after which Europe was visited and the representatives attended a conference at the League headquarters in Geneva. In 1920 he was made a Fellow of the Royal Institute of Public Health in England.

Dr. Seymour was born in Goderich, Ont., in 1857 and received his early education at Assumption College, Sandwich, Ont. He was graduated from the medical college of McGill University in 1879 where he received his degree of M.D.C.M. He obtained his degree of Doctor of Public Health from the University of Toronto. Ottawa University conferred upon him the degree of LL.D.

He was appointed Commissioner of Public Health for the Province of Saskatchewan in 1906 and in that same year he was instrumental in organizing the Saskatchewan Medical Association.

Dr. Seymour has always taken a keen interest in the fight against tuberculosis

MAURICE M. SEYMOUR, M.D.

and through his foresight and by his energy the Saskatchewan Anti-Tuberculosis League was organized and the first tubercular sanatorium in that province was built.

PUBLIC HEALTH NURSING SECTION: Elizabeth L. Smellie, R.N., Ottawa, Ont.

NEW A. P. H. A. BOOK LIST

The new *Catalogue of Health Books* of the A. P. H. A., carrying 773 titles, is ready for distribution. The Book List this year includes 53 more titles than the list of 1927. It suggests titles in the fields of child, maternity and school hygiene; food, nutrition and drugs; health education; industrial hygiene; laboratory; mental hygiene; nursing; personal hygiene; preventive medicine and public hygiene; public health engineering; social hygiene and eugenics; tuberculosis; vital statistics; reference and medical history.

This bibliography on public health is prepared for the purpose of aiding the public health worker to find the sources that will be most helpful to him in his special field of work. In the preparation of this list the American Public Health Association does not assume the responsibility of endorsing these titles—the list is compiled only as a suggested bibliography. However, a committee on public health books, which includes specialists in every field listed in the bibliography, have given assistance

in its compilation, and the Association is grateful to them for their suggestions.

The publishers' output this year has, to a degree, influenced the increase of titles appearing in the following sections of the bibliography: Preventive Medicine; Laboratory; Mental Hygiene; Personal Hygiene; Child, Maternity and School Hygiene; Health Education; Nursing; Reference Books and Medical History.

The new book list will be mailed to members of the A. P. H. A. and distributed at the Book Exhibit at the 57th Annual Meeting at Hotel Stevens, Chicago, Ill., where selection of the books listed may be made.

DEATHS OF A. P. H. A. MEMBERS

John Archibald Smith, Secretary of the American Heart Association since February, 1928, died suddenly on August 20. Dr. Smith was Secretary of the New York State Department of Health from 1917 to 1921.

Cressy L. Wilbur, M.D., for many years one of the most widely known vital statisticians in the world, died on August 9, 1928, of pneumonia. He served as Chief of the Division of Vital Statistics of Michigan, 1893 to 1905, and, as Chairman of the American Public Health Association Committee on Vital Statistics, secured the government's adoption of the International Classification of Causes of Death.

Edward A. Holmes, M.D., Health Officer of Colchester, N. Y., since 1901, died on August 19, 1928. Dr. Holmes also served as Health Officer of Downsville, N. Y., since May, 1921.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Preventive Medicine—The need of effectively controlling cults and pseudo “practitioners” of medicine by enlisting the coöperation not only of the medical profession, but also the leaders of community thought, is emphasized. Development of public health administration in this country has not infrequently been of the hit-and-miss type, resulting in a crazy quilt pattern of administration. Even in the large cities the health administrator is frequently one who has not qualified as a student in public health science and has but infrequently obtained the degree conferred upon those who study in our better grade institutions of learning. Governmental guidance would do much to prevent such haphazard development in the administrative field and would be effective in preventing many needless epidemics such as the Montreal typhoid situation of last year. The Federal Department of Health might very well have the effect of establishing a standard in public health work analogous to the service that is rendered by the Bureau of Standards with respect to basic weights and measurements. The position of the administrator in England is a striking contrast to the chaotic condition that prevails in this country. A more effective and wholesome respect for public health work can be inculcated into the medical profession by the teaching of preventive medicine at medical centers.—Louis I. Harris, M.D., *Proposals for the Next Steps in Preventive Medicine and Public Health, J. A. M. A.*, XCI: 529 (Aug. 25), 1928.

Control of Typhoid Fever—In the monthly bulletin of the New Haven Department of Health for August, 1928,

the story of typhoid fever in New Haven is traced from the year 1873 down to date. It shows that in those early years, 1873, 1874 and 1875, unquestionably typhoid was due in a large measure to the filthy condition of the soil of the city from privy vaults and the drainage of these vaults finding its way into wells. It was not until 1893 that the Common Council passed an ordinance compelling the sewer connection of all premises, or abolishment of all privy vaults and cesspools on sewered streets within 50 feet of any house. In 1896, the first milk epidemic was recorded. In 1901, 696 cases and 101 deaths from this disease occurred in the city, most of which were traceable to the pollution of Lake Dawson, a reservoir of the water supply, by the washing of excreta from the watershed into this reservoir. Milk infection from two different farms was reported in 1906, and 1911 showed a milk infection traced back to a privy vault. In 1914, all privy vaults on sewered streets were ordered abolished, and in 1915 a typhoid carrier was found in one of the wards. In the years 1915 to 1917, other equally dangerous vaults were found to be centers of summer typhoid and were abolished. Likewise in 1924 and 1927 a cesspool and an old privy vault temporarily used as a comfort station were found to be centers of infection.

Thus, the bulletin concludes, it has come to pass that the main paths of the causes of typhoid fever have been increasingly blocked by administrative action eliminating privy vaults, cesspools, and wells, and by throwing all known safeguards upon milk production. Further, a public service corporation, the New Haven Water Company, has made all storage drinking water adequately safe by clearing all the watersheds of any inhabitant.

In this review of New Haven's typhoid history there is a summary of the administrative practices which health officers must continually keep in working order to protect their communities.

Goiter Prevention—The author concludes that there is no basis for the statements that iodized salt may induce hyperthyroidism. The etiology of hyperthyroidism lies within the individual. These etiological factors are increased or aggravated by endemic goiter, and by preventing endemic goiter we are thereby preventing, in the future, many cases of hyperthyroidism. These conclusions are the result of a goiter survey of school children made in 4 counties and several urban communities in Michigan in 1924, and a re-survey in 1928. Iodized salt has been in rather general use in this state during that period. In Midland County it was found that of 3,645 school children examined in January, 1924, 41.6 per cent had goiter. A re-survey in January, 1928, showed that 91 per cent of the homes of the public school children used iodized salt. The incidence of goiter among children had decreased to 8.8 per cent. In Wexford County the first examination showed 55.5 per cent to be goitrous and in the re-survey 17.3 per cent had goiter. In the city of Grand Rapids, 1923, 30 per cent of 26,215 pupils had goiter, while a re-survey showed the percentage of goiter of 9. It was found that 91 per cent of the homes of public school children were using iodized salt.

The author analyzes the effects of iodized salt on adults with goiter and concludes that there is no indication of any danger from the use of such salt.—O. P. Kimball, *Efficiency and Safety of the Prevention of Goiter*, *J. A. M. A.*, XCI: 454 (Aug. 18), 1928.

Cancer Control—A special study has been made of the methods of cancer treatment and control in 20 average American cities ranging in population from 100,000 to one million. It was recommended that the records of cancer cases should be pooled through individual follow-up reports or through a central bureau embracing the hospitals of the city. Also, there should be more concentration on the laboratory diagnosis of cancer, especially in smaller communities. Cancer clinics, to function properly, must be carefully established and must proceed slowly. There should be physicians having a proper pathological understanding of cancer, capable of treating cancer or developing into experts. In some of the large hospitals it would be well to refer cancer cases to groups of certain physicians on the staff who have the time and inclination to study such cases. In some communities it would be better if early cancer were not treated, the patients being sent instead to a nearby center where facilities and the opportunity for wide experience with the disease are more easily obtained.—Harry C. Saltzstein, M.D., *Average Treatment of Cancer*, *J. A. M. A.*, XCI: 465 (Aug. 18), 1928.

C. C. YOUNG

COMPARATIVE RESULTS IN THE BACTERIOLOGICAL EXAMINATION OF FECES

AUBREY H. STRAUS, FELLOW A. P. H. A., and FORREST SPINDLE

Laboratories, Virginia State Department of Health, Richmond, Va.

THE excellent results obtained by the use of brilliant green bile in the bacteriological examination of feces published by Havens¹ has naturally attracted much interest among public health laboratory workers. As most public health laboratories have for some years employed the method described by Teague,² that is, the use of 30 per cent glycerine, the question has naturally arisen as to which of these two methods would give the most satisfactory results under practical working conditions.

In an endeavor to determine this point a series of comparative specimens has been obtained. Dr. Havens was kind enough to supply us with brilliant green bile prepared in his laboratory for this purpose. Two different batches of brilliant green bile were received and used, but Dr. Havens has subsequently stated that the dye used in this media was from one of the poorest lots he has had. A special outfit for collecting samples was used containing two identical bottles, one of which contained 30 per cent glycerine and the other brilliant green bile, approximately the same amount of fluid, 8 to 10 c.c., being put into each bottle. These containers were supplied to our epidemiological department and also to our county health officers. They were requested when obtaining specimens of feces to put as nearly as possible the same amount of material into each bottle, the specimens then being mailed to the laboratory.

The quantity of feces used was in most cases quite small, about the size of a pea.

Upon arrival at the laboratory the specimens were immediately plated, successive platings being made the day following arrival and the day after that, so that each specimen was plated on three successive days. The specimens from the glycerine were plated only on eosin-methylene-blue agar, this being the usual custom in this laboratory. The specimens in the brilliant green bile, however, were plated both on eosin-methylene-blue agar and on Krumwiede's brilliant green agar according to the method described by Havens. That is, we endeavored to follow Havens' technic exactly on the brilliant green bile specimens, at the same time plating them also on eosin-methylene-blue agar for comparative purposes.

While large numbers of these containers were sent out, up to the present time only 52 specimens have been returned to the laboratory. The specimens came from 34 cases of suspected typhoid fever, 5 cases of suspected dysentery, 12 suspected carriers and 1 of unknown origin. All positive specimens came from clinical cases.

The results of these 52 comparative tests are as follows:

Specimens Examined	
52	
Number Positive for Typhoid	
(a)	(b)
Brilliant green bile	Glycerine
10	18

One specimen found positive by method (a) was negative by (b), but 9 specimens positive by method (b) were negative by (a). There were likewise 3 cases of Flexner dysentery found positive by method (b), which were not found by the brilliant green bile method.

It is also interesting to note that the specimen positive in the brilliant green bile only was likewise positive only on the brilliant green agar plates, the eosin-methylene-blue plates being negative. In one other case positive colonies were obtained from the brilliant green agar and not on the eosin-methylene-blue, but in all other cases the eosin-methylene-blue plates gave excellent results.

Thirteen specimens from the brilliant green bile showed no growth on any plate. In no case was there any evidence of overgrowth.

In all 3 cases showing Flexner dysentery no growth was obtained from the brilliant green bile, while positive results were obtained from the glycerine at the end of three days, the plates showing almost pure cultures of dysentery bacilli.

SUMMARY

The bacteriological examination of feces in the State of Virginia is carried out both for diagnosis and for the finding of carriers. Bacillary dysentery is more common than typhoid fever, and carriers of this disease are likewise, in our observation, more numerous than carriers of typhoid. Brilliant green bile is not suitable for the examination of specimens for bacillary dysentery. It, likewise, did not in this series give as good results in the examination for typhoid as did 30 per cent glycerine.

While it is realized that this series of results is small they are nevertheless significant and the examinations have been made under practical working conditions. It is, therefore, our opinion that 30 per cent glycerine is decidedly superior to brilliant green bile as a practical method in public health practice.

A SIMPLE DILUTION BOTTLE STOPPER ARRESTOR

MILTON E. PARKER

Dairy Technologist, Philadelphia Dairy Products Co., Inc., Philadelphia, Pa.

A SIMPLE dilution bottle stopper arrestor can be made by means of a small piece of 6 mm. glass rod. By bending the glass rod into a series of suitable angles, as shown in Figure I, and inserting one end into the single opening of a one-holed No. 2 rubber stopper, the appliance is complete.

The original purpose of devising such an appliance was to permit the preparation of dilutions of ice cream samples by weight. By means of suitable carrier pans designed to hold one Pyrex dilution bottle each with load of 100 gm., it was found convenient to utilize a torsion balance sensitive to 0.01 gm. The stopper arrestor provides the means

of maintaining the tare without the danger of contamination.

FIGURE I

STOPPER ARRESTOR FOR USE WITH PYREX
DILUTION BOTTLE
(Half Size)

Reference to Figure II will demonstrate the ability of the stopper arrestor in the preparation of ice cream sample dilutions by weight without the danger of contamination.

In Figure II the Pyrex dilution bottle on the left shows the position of seal of

ICE CREAM SAMPLE DILUTIONS BY
WEIGHT

the stopper and arrestor before and after dilution, while the bottle on the right indicates the positions of stopper

and arrestor during diluting by weight. In our laboratory we prepare the dilution bottles with 90 c.c. of sterile distilled water and use 10 gr. of melted ice cream for preparing an original 1/10 dilution. All other dilutions are prepared from this original dilution.

Additional advantages of the stopper arrestor have come to our attention with the use of this appliance. It was found that with the considerable ejection of non-absorbent stoppers during autoclaving, this could be reduced to a minimum by means of the arrestor, with never an instance of the stopper leaving the bottle entirely. A quick tap at the top of the stopper with a glass rod will invariably return the stopper to the position of seal, thus maintaining sterility. Furthermore, in the actual manipulations during diluting, plating, etc., it makes it possible to prepare and withdraw portions for plating without removing the stopper entirely from the bottle, thereby again reducing possibilities of contamination during the execution of the usual details of bacteriological laboratory technic.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

The Health of Calcutta—The latest available annual report of Calcutta is for the year 1925, published in 1927. Calcutta has an area of 30 square miles and a population of over a million; a birth rate of 19, a death rate of 33, and an infant mortality of 326. The population should therefore be decreasing by no less than 15,000 per annum. There are about twice as many males as females, and the death rate of females is nearly double that of males. The death rate of the Mohammedans is considerably higher than that of the Hindus, and

the infant mortality of the former 429, against 306 of the latter. The birth rate when calculated from the number of women of childbearing age is 59 for Hindus, 65 for Mohammedans, 52 for Anglo-Indians and 61 for Indian Christians. There is a seasonal variation for births, the rates being low in summer and high in winter.

In 1925 there was a severe epidemic of smallpox of very virulent type, causing a death rate of 3.6 per 1,000. The disease of kala-azar has been increasing steadily during the past seven years.

The death rate from this is now seven times what it was 17 years ago. The disease is about twice as fatal in Anglo-Indians and native Christians as in Hindus and Mohammedans.—*Med. Off.*, 40: 25 (July 21), 1928.

Toxemia in Pregnancy—Over 70 per cent of the cases studied were primiparae, and more than 50 per cent were between the ages of 25 and 35 years. In a number of cases there was a family history of toxemia, most often of the patient's mother. Fibroids were noted in 5 cases. There were twins in 3 cases. Convulsions took place in 8 primipara cases and in 1 multipara, with one death, a primipara. There were 22 chronic nephritics with 3 deaths occurring among them. One hundred fifty-six pregnancies were recorded in 56 cases. Ninety-eight babies lived, and 61 pregnancies terminated in death to the fetus.

An analysis of 400 consecutive cases coming for delivery showed that 5.5 per cent developed toxemia. Of these, 4.25 per cent were acute toxemic cases and 12 per cent of the cases were recurrent toxemias. The toxemics who have had prenatal treatment and develop convulsions suddenly, because of an acute fulminating condition, have a better chance of surviving, if properly treated, than those who have not had this care.

Although toxemic symptoms should be treated in a hospital, operative intervention is not necessary unless symptoms increase. In toxemias developing prior to six and a half months, the danger of eclampsia is too great to allow the pregnancy to continue. Delivery before severe toxemia develops will reduce maternal mortality.—Reginald D. Mergeson, *New England J. Med.*, 198: 735-739 (May 24), 1928.

Infant Mortality—Figures for New Zealand show that infantile mortality has fallen from 100 in 1880 to 40 in

1926; the deaths of infants 1-2 months, from 67 to 14; the deaths of infants under 1 month, from 29 to 25. But the stillbirths have risen from 23 to 30 since 1913. The increase of natal deaths is attributed to the diminishing birth rate, producing an increasing proportion of first births, and probably increasing the age of primiparae.

It has been proposed that infantile mortality rates be recorded in more detail, as follows: (1) Deaths of infants under 1 year per 1,000 live births; (2) Deaths from 1 to 12 months per 1,000 live births; (3) Deaths of infants under 1 year per 1,000 live births; (4) Stillbirths per 1,000 total births; (5) Deaths under 1 month together with stillbirths per 1,000 total births.

There are three groups of causes of early death, non-viability and disease of the embryo, damage by the process of birth, and post-birth disease. The first may cause death from the time of conception to the end of the first month of extra-uterine life; the second, during birth or within the first week of separate existence; the third, from the end of the first week onwards. Congenital syphilis is a cause of death, but recent research shows it to be less prevalent than is generally believed. Toxemia is assumed from the latest research to be a disease of the embryo, but it is for clinical purposes a maternal disease.—*Med. Off.*, 40: 11 (July 14), 1928.

Endemic Goiter in Massachusetts—In the fall and winter of 1925-1926, the Massachusetts Department of Public Health in coöperation with the U. S. Public Health Service conducted a goiter survey in 55 towns and cities of Massachusetts. There were 12,270 students examined for goiter. Seventeen and six-tenths per cent were found goitrous. The goiter rate among children whose parents were born in Russia is higher than for children of other parents. Tabulations show that there is no dif-

ference between the goiter group and the non-goiter group with respect to height, and only a slight difference in weight. The mean weight for children with goiter is slightly less than for those without. The presence or absence of communicable diseases such as chicken pox, measles, mumps, whooping cough, scarlet fever, poliomyelitis, rheumatism, convulsions and diphtheria, or the presence of enlarged tonsils, adenoids, cervical glands and dental caries, has no apparent effect on goiter incidence. Fifteen and seven-tenths per cent of the children with goiter, and 13.1 per cent of the children without had poor posture.

There were 39 places with information regarding iodine content of drinking water and goiter incidence. The correlation was not large, but consistent with the impression that lack of iodine content in water is to some extent responsible for development of goiter.—Carl R. Doering, Herbert L. Lombard and Fredrika Moore, *New Eng. J. Med.*, 199: 143–145 (July 19), 1928.

Vital Statistics of Germany in 1926—A report of the federal health bureau on the vital statistics of Germany for the year 1926 shows that the decline in the birth rate has continued on into 1927 and has led to the lowest rates ever recorded. Nor is the decrease in birth rate confined to the large cities, as is commonly assumed, but it is a manifestation under which also the rural districts are beginning to suffer to an alarming extent. In communes with 15,000 and more inhabitants, the number of legitimate living births in 1926 was only 13.3 per 1,000 inhabitants, so that for each marriage of that year there were only 1.6 living births, whereas the proportion for the whole reich in 1925 was 2.4, and in 1900 was about 4. The infant mortality, on the other hand, has been reduced. With a mortality of 10.1 per 100 living births, the death rate for 1926 reached the lowest recorded

level. The mortality rate, on the average, for the decade 1901–1910 was 18.1 per 100 living births. Also the mortality of young children aged 1 to 5 was further reduced, one of the lowest death rates for that period of life in Europe being attained. In a comparison of the death rates of the cities and the rural districts, it appears that the large cities have the lowest infant mortality, whereas the mortality of children over 1 year of age is distinctly higher in the cities than in the small communes.

There was a marked decrease of tuberculosis mortality. The figure is only slightly higher than the minimum tuberculosis mortality for Europe, as recorded in Denmark and in England. Conditions are much less favorable with regard to scarlet fever; the number of cases and also the mortality show in 1926 a still further increase. Measles has abated greatly; diphtheria has retrogressed somewhat, while whooping cough presents an almost unchanged incidence. There was a notable increase in the number of cases of infantile paralysis—from 1,200 up to 1,614. Influenza showed a slight increase in the case morbidity, though, in the main, it is taking on again the character of a disease claiming its victims almost exclusively among the very young and very old, its manifestations being now much the same as before the war. Also the number of suicides, especially in the smaller communities, shows an increase.—*J. A. M. A.*, 91: 188 (July 21), 1928.

Poliomyelitis Work in Vermont—The 1927 Yearly Report of the After Care Division of Poliomyelitis shows that 954 patients were under supervision. Poliomyelitis cases when reported to the Department of Health are followed up first by the research worker, and then by after care nurses.

There were 183 new admissions and 878 clinical examinations made during the year. The charts show that the

number of patients under supervision has doubled since 1920, and that the number of patients seen during the year has almost tripled.

There were 40 new cases of poliomyelitis for the year. Thirty-five of these were seen. Thirty-one needed after care treatment, 2 were abortive, 1 was a practical recovery and 1 died. Of the 5 cases not seen, 1 was abortive, 2 were practical recoveries, and 2 died. The muscle involvement was high and the paralysis severe for the year. In the group of 31 cases under supervision there were 32 paralyzed legs. Twenty-four arms and shoulders were paralyzed, 5 of which were also practically flail, and showed little sign of recovery. Sixteen patients had considerable trunk paralysis.

Where recommended treatment was followed, patients, with the exception of those with completely paralyzed muscles, showed improvement in muscle strength. Even in the most severe cases deformities due to contractions had not developed. Craft work is taught to many of the patients, and it is reported that 3 have learned a craft that they can make and market themselves.—Charles F. Dalton, *New England J. Med.*, 198: 755-758 (May 24), 1928.

Epidemiology of Diphtheria—New-born infants of Schick-negative mothers are found to be Schick-negative, but at 9 to 12 months of age 90 per cent of infants are Schick-positive. The proportion found naturally Schick-negative increases progressively with age. The proportion of Schick-negatives is generally higher in urban than in rural populations, and higher for children in institutions and congested districts than in less crowded areas. Ap-

proximately 95 per cent of the institutional children between the ages of 10 and 14 in New York City were found to be Schick-negative, whereas only 72 per cent of the school children were negative.

In Auburn, N. Y., about 41 per cent showed negative tests; and in rural Vermont only 22 per cent of the school children were negative.

From 1922 to 1925, 9,000 white children under the age of 15 residing in six wards of Baltimore were Schick-tested. About 68 per cent were Schick-negative when they reached the age of 15; 52 per cent at the age of 10; and 21.5 per cent at the age of 5. About 12 per cent of the children aged 15 had had a previous attack of diphtheria. There is an average immunization rate of 6.1 per cent per annum in the second 5 years of life.

In white children the ratio of disease to bacteriologically demonstrable infection seems to vary according to the circumstances of exposure. In families in which a case of clinical diphtheria has occurred, it was found in Baltimore that of family contacts aged 5 to 14 (exclusive of those who have received prophylactic injections of antitoxin), 4.33 per cent develop diphtheria within 30 days following the onset of the primary case. Of the contacts aged 5 to 14, 24.6 per cent become carriers of virulent bacilli without developing the disease. Therefore, among the children of this age exposed to infection by living in the house with a case of diphtheria, the ratio of carrier infection to clinical diphtheria is 6 to 1, whereas it has been found that in children exposed at school the ratio is 47 to 1.—W. H. Frost, *Infection, Immunity and Disease in the Epidemiology of Diphtheria. J. Prev. Med.*, 2: 325-343 (July), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Report of Proceedings Eighth Annual Conference International Association of Street Sanitation Officials—As a part of the report of a committee to study costs and methods of various garbage disposal systems, there are included answers to circularized letters of inquiry which were mailed to about 200 cities in the United States. Tabulations are given showing pertinent facts relating to the methods of garbage collection and disposal now employed in these cities. It is stated that the essential features of an efficient garbage collection and disposal system include: (1) sanitation, (2) service, (3) economy, (4) dependability and flexibility, and (5) expediency. Various garbage disposal methods discussed include dumping, reduction, incineration, burial and plowing in and the Beccari process. This article is an excellent summary of the methods now employed in many of our larger cities. Jan., 1928, pp. 43-54. Abstr. W. L. Havens.

Treatment of Packing Plant Wastes—A description is given of the activated sludge plant operated by the Iowa State College Engineering Experiment Station at the packing works of J. E. Decker & Son, Mason, Ia., with an outline of operating experiences. The plant consists of a Dorco rotary screen, primary settling tank, two aeration tanks, secondary settling tank and a sludge re-aeration tank. Both settling tanks are of the Dorr type, equipped with thickeners. The average hourly flow varied from 200 to 490 g.p.m., dropping to 125 g.p.m. on Sundays. During periods of low flow, difficulties were experienced due to the primary settling tanks becoming septic, this condition giving rise

to disturbances in the purification process. With a sludge return of 50 g.p.m., the theoretical detention period in the sludge re-aeration tank is $5\frac{1}{2}$ hours. This tank, which was installed after the plant had been in operation some time, has effected a great improvement. The short period of aeration has little effect, however, when the sludge is septic. Increasing sludge return to 150 g.p.m. by returning sludge directly to the aeration tank during low flow periods has been found to facilitate the building up of a large amount of sludge for use when the flow increases.

One of the most troublesome factors encountered has been the rising of sludge in the final settling tank. This occurs when the sludge is under- or over-aerated, or slightly septic. Applying a continuous spray of water to the scum formed has been partially successful in causing the sludge to re-settle. Carefully controlling the air supply is the best method of combating this condition.

On some days extreme foaming has occurred in the aeration tanks, the foam at times covering the tanks to a depth of 6 ft. and the ground to a depth of 1 to 4 ft. for a distance of 50 ft. Foaming apparently occurs at certain intervals when the tanks are changing from an under-aerated to a fully aerated condition. Probably the most effective remedy would be either the use of oil in the tanks or the application of a flat, horizontal spray of water which would tend to cut the foam.

To correct unequal distribution of air the tanks were dewatered and cleaned. A heavy deposit of sand and organic matter was found on the entire bottom of the aeration tanks to a depth of 4-6 inches. The filter plates were cleaned

by scrubbing, soaking in hydrochloric acid (sp.gr. 1.14) and finally washing with hot water applied through a nozzle under pressure. The method employed for testing the loss-of-head through the plates before replacing them is outlined.

Experiments have been carried out on dewatering the sludge with an American Continuous Filter. The primary sludge, which contains 6 per cent dry solids when treated with 10 lbs. of alum per 1,000 gals., filters readily to 71 per cent moisture. A few determinations have indicated an erratic solid content in the activated sludge varying from 0.25 to 1.5 per cent. A mixture of 75 per cent activated and 25 per cent primary sludge treated with 5 lbs. alum per 1,000 gals. gave a cake with 75 per cent moisture or a little higher. A few tests with ferric chloride also gave good results, but the moisture content of the cake was somewhat higher. The mixture of sludges filters more rapidly than the primary sludge alone. It is not expected that the plant will be able to treat successfully the wastes during the approaching peak killing season.—Frederick G. Nelson, *Canad. Eng.*, 53, 25: 627 (Dec.), 1927. Abstr. R. E. Thompson.

Industrial Waste Research Problem in Southern California—Southern California has about 5,000 industries, many of which have serious difficulties in disposing of liquid wastes. No streams are available for dilution, and inland towns will be dependent on high grade treatment with disposal on land or in dry stream beds.

Research in industrial wastes is a logical extension of research in sewage disposal. Factors of temperature, staleness of sewage reaching plants due to low grades or long travel, and variable quality of sewage constituents due to high fruit and vegetable diets, all tend to make the problem of sewage disposal different from that in the East. The

industrial wastes are also different, and separate study must be made of each kind of waste.

The only practical solution of the problem seems to be to have a research organization either as a part of the Department of Public Health, the Department of Natural Resources, or some other state department. Private engineers cannot afford to carry on this kind of research; industries will not carry it on unless forced to do so; salesmen can only try out their equipment, which is not likely to bring about fundamental solutions; student theses are not sufficiently prolonged to allow a complete solution; and the various organizations now working intermittently are not equipped adequately to handle the work.—R. F. Goudey, *Western Construction News*, 3, 1: 18 (Jan.), 1928. Abstr. E. A. Reinke.

Relation of Turbidity to Coagulant Dosage—In this paper is described the relation of the turbidity to the coagulant dosage as observed at the Omaha, Neb., filtration plant. From a series of tests by permitting river water to settle in a 5½-ft. glass cylinder for various lengths of time and then siphoning off samples for turbidity tests, it was found that the coagulants required could be determined by the results of the 3-hour settling tests.

During periods of high turbidity (10,000 p.p.m.) the application of coagulants at two points has been extremely helpful in delivering a satisfactory water to the filters. The effect of various turbidities on the coagulants required, also the results of the settling tests, are given in detail and shown on various charts of operation for June and July, 1926, and May, 1927.

The following conclusions are given: (1) The suspended material is chiefly responsible for variation in coagulant dosage; (2) coagulant dosage can be determined largely by the results of the 3-

hour turbidity test; (3) two-point application of chemicals is helpful in treating very turbid water; (4) the 24-hour turbidity test gives a good indication of the concentration of finely divided material, some of which is of colloidal nature.—Kenneth C. Armstrong, *Am. City*, 38, 2: 100 (Feb.), 1928. Abstr. J. B. Harrington.

Water Pollution Control, Milk Products Wastes—This bulletin presents a compilation of several important findings on the treatment and purification of milk products wastes. Investigations conducted in Massachusetts, Wisconsin, New Jersey, New York, Ohio, Iowa, and by the U. S. Public Health Service are noted with a brief discussion of the results found.

The experiments conducted at the Michigan State College in coöperation with the health department are discussed in more detail. Preliminary laboratory experiments indicate that in using the chemical precipitation method a good floc is secured and efficient settling occurs when sufficient quantities of ferrous sulphate and caustic soda are used. At least 0.6 p.p.m. of ferrous sulphate must be used or the precipitate will be red in color. Lime or caustic soda in quantities sufficient to produce a pH of 7.5 to 8.0 will give a good floc with good settling, but produces a large amount of sludge. Broad irrigation of milk products wastes is recommended as a temporary expedient where possible.—E. F. Eldridge, J. M. Hepler and H. S. Murphy, Department of Health and Department of Conservation, Michigan, June, 1927. Pamphlet 15 pp. Abstr. D. W. Evans.

Digestion of Vegetable Wastes and Screenings in Sewage Treatment Plants—Comprehensive researches in the digestion of mixtures of garbage, screenings, fresh sewage solids and digested sludge were made to ascer-

tain whether garbage could be digested with the sludge at sewage disposal plants. Studies in the digestion of vegetable wastes from canneries will be made in the future. It was found that mixtures of vegetable wastes and fresh sewage solids digested very slowly; that the addition of ripe sludge greatly hastened digestion; and that lime dosing still further hastened digestion. The rate of digestion of vegetable wastes and screenings is slow due to production of acids, which inhibit growth of putrefactive organisms. The addition of lime neutralizes acidity; the addition of ripe sludge seeds the mixture; and the addition of fresh sewage solids provides the nitrogenous wastes necessary for normal digestion. It was concluded that vegetable wastes and screenings may be digested in sewage tanks provided the sludge capacity is adequate and provided the ratio of sewage solids to vegetable wastes (nitrogen to carbon) is large. The allowable ratios in practice will be determined by further studies.—W. Rudolfs and H. Heukelekian, *Water Works*, 67, 3: 113 (Mar.), 1928. Abstr. C. R. Cox.

Seeding New Tanks—The difficulty sometimes experienced in starting the operation of a new tank was deemed of sufficient importance to warrant laboratory experiments in order to determine what could be substituted for ripe sludge when the latter was not available. Definite quantities of fresh solids were mixed with ripe sludge, horse manure, cow manure and muck from a creek and results compared with fresh solids seeded with ripe Imhoff sludge. It was found that neither manure nor muck is so effective for seeding as ripe sludge. Muck was about half as good as ripe sludge and horse and cow manure still less. If sludge from a polluted stream is available for seeding it is to be favored. Seeding with horse manure and additions of lime are beneficial but

still inferior to seeding with ripe sludge. Addition of lime to fresh solids when ripe sludge is present for seeding keeps floating solids down.—William Rudolfs, *Report of the Department of Sewage Disposal of the N. J. Agriculture Experiment Station for year ending June 30, 1927*, pp. 284–94. Abstr. W. L. Havens.

Milk Supply—In the May issue of this JOURNAL there appeared the Report of the Committee on Milk Supply as presented to the Public Health Engineering Section at the last Annual Meeting.

The first part of the report relates to the standardization of equipment of rooms in which milk is handled. This leads into the methods of cleaning and handling apparatus; the definition of pasteurization with methods for operating pasteurizers, and several other questions.

The clear-cut style in which the report is prepared makes it easily understood. The complete report is worthy of study by all sanitarians.

Tadpole of the Spadefoot Toad an Enemy of Mosquito Larvae—Tadpoles of most toads and frogs are herbivorous and live in entire harmony with mosquito larvae. The tadpole of the spadefoot toad seems to be “de-

parting from the traditions of its ancestors and relatives and adjusting itself to a new type of diet.” The larger tadpoles of the spadefoot seem to live on a strictly carnivorous diet, the structure of the mouth being adapted for seizing and holding the prey, and are active and efficient enemies of mosquito larvae, as proved by certain laboratory and field experiments recorded in the article.

The toad has the advantage over fish in being able to travel overland to new habitats after the fish have been killed by previous drying-up of the water.

The season of the spadefoot toad is usually short and limited to early summer. This is a marked disadvantage as an enemy of anopheles, as well as other mosquito larvae. Its range is western and it is to be proved whether it might be possible and worth while to colonize it in other regions.

On the whole, no such antilarval efficiency can be expected of this tadpole as is exhibited by certain larvivorous fish; but its propagation, if such is practicable, could not interfere with any other enemy of mosquito larvae, and the more abundant and the greater the variety of natural enemies of mosquito larvae the better. The spadefoot would probably find its greatest usefulness in localities where there is extensive breeding of mosquitoes in shallow, temporary waters.—

M. A. Barber and C. H. King, *Pub. Health Rep., Reprint No. 1200*, Dec., 1927. Abstr. C. H. Kibbey.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Intoxication with Commercial Methyl Chloride—The introduction of household refrigeration machines in which methyl chloride is used as a refrigerant has served to bring about a number of cases of poisoning with this substance in manufacturing plants engaged in making these refrigerants. Dr. Baker found that the gas is absorbed in amounts sufficient to produce intoxication unless precautions are exercised against this. The symptoms range from vertigo, staggering gait, sleepiness to nausea, anorexia and loss of weight. The detection of methyl chloride in the urine as ammonium formate prior to the development of symptoms of intoxication is suggested as a possible method for the control of the industrial disease.—H. N. Baker, *J. A. M. A.*, 88, 15: 1137 (Apr. 9), 1927. L. G.

Trend of Disabling Sickness among Employees of a Public Utility—The morbidity statistics of a large public utility situated in Massachusetts covering the period 1917–1927 were analyzed, with respect to the cause of disability, under five main groupings: industrial accidents, nonindustrial accidents, diseases of the respiratory system, diseases of the digestive system, and all other diseases.

The most important findings which these studies disclosed were the following: Disabling industrial accidents among the male employees showed a downward trend; on the other hand, diseases of the respiratory and of the digestive systems, which together caused nearly 70 per cent of the disability, exhibited a stationary trend. The author points out that the experience of this group should not be considered as typi-

cal or representative of the whole of the industrial population of the country, since the sample is rather small. The data, nevertheless, are of much value in casting light on the problem of sickness in industry.

The author further points out that in order to be productive of results preventive measures will have to be exceedingly definite in their application. In his opinion money and effort will be wasted if spent "on general principles." The common cold and indigestion as causes of industrial absenteeism are of paramount importance.—Dean K. Brundage, *Pub. Health Rep.*, 43, 30: 1957–1984 (July 27), 1928. L. G.

Benzol Poisoning as a Possible Hazard in Chemical Laboratories—The writer of this paper calls attention to the fact that benzol is often used in chemical laboratories in the making of certain tests and in the cleaning of glassware. Studies made in certain laboratories where benzol was used for these purposes indicated that while a lowering of the number of white blood cells (generally used as one of the indications of benzol poisoning) was not in evidence, the change in the percentage composition of various white blood cells was apparent on examination of the exposed persons. For this reason the author calls attention to the fact that benzol may constitute a real hazard in chemical laboratories.

The amount of benzol used in the average chemical laboratory for the purposes mentioned is so small that a more expensive solvent might be substituted without any real increase in upkeep of the laboratory. It should be possible to substitute some less toxic solvent, such

as toluol, xylol, or naphtha, such as recommended by the National Safety Council in its studies made on benzol poisoning.

In conclusion, it is recommended that all laboratory workers exposed to benzol fumes be given a thorough medical examination every month or two.—J. J. Bloomfield, *Pub. Health Rep.*, 43, 29: 1895–1897 (July 20), 1928. L. G.

Skin Eruptions in Industry—Dr. Mayers is of the opinion that there are few substances, no matter how innocuous to the average individual, which could not cause severe dermatitis in persons having a particular idiosyncrasy to them, citing the case of poisoning of a worker who was engaged in a factory wherein scented face powder was manufactured. The face powder apparently was used by thousands of consumers in the United States without ill effect, and yet this worker, apparently sensitive to some of the flower extracts in the powder, fell ill with a severe dermatitis.

In conclusion, Dr. Mayers points out that cases of dermatitis are at the present time regarded as occupational diseases and are covered by the law of the State of New York relating to these diseases.—May R. Mayers, *Indust. Hyg. Bull.*, V, 2: 5 (Aug.), 1928. L. G.

Atmospheric Smoke Pollution and Its Relation to Public Health—Many of us today are inclined to believe that the smoke problem was the product of intensive urbanization of the last few years. Such, however, is not the case. In this interesting contribution, Mr. Bloomfield points out that early in the 14th century a royal proclamation was issued in England prohibiting the use of sea coal in the furnaces of metal workers, and it is even recorded that one man who disobeyed the King's edict was executed in London for this crime.

Smoke has two effects upon health, the direct effect produced by the inhalation of this material into the lungs of the exposed persons, and the indirect effect, namely, the obliteration of sunshine and its health-giving rays. The author points out that city air is polluted by soot from burning coal, by gases, and lastly by dust from the ordinary occupations taking place in the city. The two most important gases present in city atmosphere are carbon monoxide and sulphur dioxide, and it is fair to say that under ordinary circumstances both of these are present in such small concentrations that they may be considered harmless so far as the average city dweller is concerned.

The present paper contains one of the most rational discussions on the effect of soot on the health of city dwellers with which the reviewer is familiar. To one versed in the methods of scientific inquiry it must be apparent that the proof of a question of this type is exceedingly difficult. Mr. Bloomfield's paper shows that the data and statistics so far brought forward do not permit one to arrive at a definite conclusion on this point. There is no doubt that soot is annoying, discomforting, and unesthetic, but the proof that it is actually harmful still remains to be forthcoming.

The indirect effects of smoke are really of enormous importance, but here, once again, the proof is wanting, and for the time being, while we all are cognizant of the fact that smoke shuts off a certain proportion of sunshine and ultra-violet light, it still remains to be proved that this effect is sufficient to be called injurious to health.

The solution of the problem of smoke pollution depends on the coöperation of the mechanical engineer, the fuel engineer, and the public, according to this paper.—J. J. Bloomfield, *J. Outdoor Life*, XXV, 8: 457–462 (Aug.), 1928. L. G.

FOODS, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Septic Sore Throat Outbreak at Lee, Mass.—The epidemic of septic sore throat at Lee, Mass., which resulted in 600 cases with 36 deaths, has been officially traced to infected raw milk. Cultures of hemolytic streptococci were obtained from one of the cows and from a number of milk handlers. The first case was reported July 1 and terminated after the enforcement of a local ordinance of July 7 requiring all milk to be pasteurized. Dr. Bigelow, Health Commissioner of Massachusetts, feels certain that, as a result, the milk supply of the Berkshires is adequately supervised, and points to the moral that "raw milk is a very potent vehicle for the transmission of disease."—*Pub. Health Rep.*, 43: 2112 (Aug. 10), 1928.

La Cuisson sous Pression des Aliments (Cooking Food under Pressure)—In order to determine whether a short pressure cooking of 120° C. would be equivalent to a cooking for several hours at 100° C. in ordinary vessels, this experiment was undertaken: Two vessels exactly alike were employed, one using the ordinary method, and the other in a commercial pressure autoclave. Analyses of the products of the resultant cooks were made, paying particular attention to the distribution of nitrogen, since this permits a method of determining the degree of proteolysis. This comparative experiment was conducted with soup composed of meat, bone, vegetables and the usual condiments. Analytical figures are submitted showing the content of the material prepared by both methods—dry extract, nitrogenous material, fat material, reducible and saccharin matters, other carbohydrates, and fixed min-

erals. Analytical data are also submitted of the meat, both in the fresh state and after cooking, including determination of the total soluble nitrogen, residual nitrogen, alpha amino nitrogen, and ammoniacal nitrogen. These figures indicate: (1) that the degree of proteolysis of fresh meat is relatively increased; (2) in the soup cooked in the autoclave as well as that prepared by ordinary methods the ammoniacal nitrogen contained in comparison with the total soluble nitrogen is less than in the fresh meat.

The results respectively reported for the two methods show that the soluble nitrogen prepared by autoclave is richer in amino acids than that obtained by ordinary cooking and that it contains a quantity of ammoniacal nitrogen greater than that provided in the meat. The transformation of amino nitrogen into ammoniacal nitrogen takes place in artificial hydrolysis as well as in the natural proteolytic decomposition. It appears to take place in proportion to the increase in splitting of nitrogenous material, and under certain conditions with a rapidity equal to that in the decomposition of proteins into amino acids. From a nutritional viewpoint the production of ammonia has little importance, for even if it has not been shown up to the present that the element is harmful, it is of no particular value to the system.

In conclusion, since soup prepared in the pressure cooker contains less nitrogenous material, fat, reducible matters and dry extract than the ordinary soup, it might be said that it is less nutritive than the latter. On the contrary, the meat is better when cooked under pressure. It is contended that the pro-

cedure has advantages and some disadvantages which approximately equalize. From the economic standpoint the pressure cooker is preferable since it consumes less than one-quarter the amount of gas of ordinary cooking.—M. J. Froidevaux, *Annales des Falsif.*, 234: 252 (June), 1928.

The Effect of Large Amounts of Pineapple Juice—Recent arrivals in the Hawaiian Islands complain of discomfort after the ingestion of large amounts of fresh pineapple, which is relieved by discontinuing the pineapple and administering sodium bicarbonate. Since pineapple is regarded as potentially alkaline, and in the belief that it would not cause acidosis, four healthy women were the subject of a digestion experiment to determine the effect of this juice on the urine. After a short time on a basal diet consisting of milk, crackers, egg, apple, and butter, 1 quart of pineapple juice was added for two consecutive days, and on the third day $1\frac{1}{2}$ quarts in one subject and $1\frac{1}{4}$ quarts in another. In a subsequent experiment the basal diet was supplemented by the addition of white potato. Results reported on the urine include, total volume, pH value, titratable acidity with N/10 NaOH, and ammonia. These show that large amounts of fresh pineapple juice result in lower acidity both as indicated by the pH value and by titration and a decrease in ammonia output. These results would be expected according to the report that citric acid constitutes 87 per cent of the non-volatile acid in pineapple juice. The explanation of the apparent acidosis is attributed to the presence of calcium oxalate crystals in the juice. The fact that cooked pineapple is less irritating was explained by the activity of the crystals and the fact that the proteolytic enzyme, bromelin, is destroyed in canning.—Carey D. Miller, *J. Home Econ.*, 20: 498 (July), 1928.

Effect of Pasteurization on the Bovine Tubercle Bacillus in Naturally Infected Tuberculous Milk—In conducting the experiments reported in this article the author used naturally infected milk from three tubercular cows in order to overcome certain objections to the use of milk inoculated with cultures of tubercle bacilli, namely, that artificial cultivation yields organisms which are less resistant to outside influences than those occurring naturally, and that cultures of bacilli can have no such protective covering as is provided by cells and tissue in natural infection. Four series of experiments were conducted in which the milk was heated at (1) 62.8° C. (145° F.) for 30 minutes, (2) 60° C. (140° F.) for 30 minutes, (3) 60° C. (140° F.) for 20 minutes, and (4) 59.3° C. (138.8° F.) for 20 minutes. Guinea pigs were inoculated with the centrifugalized deposit and the cream of the heated milk, as well as with coagulated material from the cooler. In the first series 1 guinea pig, out of 118 inoculated, developed tuberculosis. In the second series, out of 100 guinea pigs inoculated, none developed tuberculosis. In the third series 1 guinea pig, out of 66 inoculated, died of tuberculosis. In the fourth series, 10 out of 12 inoculated guinea pigs developed tuberculosis. In each of the first and third series 1 guinea pig died from tuberculosis following inoculation with coagulated material from the cooler. In the third series both positive cases occurred near the end of the lactation period when the milk was abnormal.

It is pointed out that standardized thermometers must be used in commercial pasteurization but that with all precaution it is by no means always possible to exercise the strict control which obtains in the laboratory. The author concludes that temperature of 62.8° C. (145° F.) for 30 minutes does not invariably kill the tubercle bacillus in naturally infected milk, although in

most cases this temperature is effective, and that at a temperature of 60° C. (140° F.) for 20 minutes tubercle bacilli are in many cases destroyed; but this combination of time and temperature leaves no margin of safety.—L. J. Meanwell, *Brit. J. Hyg.*, 26: 392 (Oct.), 1927.

Biological Values of Certain Types of Sea Foods. III—Vitamins in Clams—The work reported was conducted similarly to experiments on oysters which were shown to be a good source of vitamins A, B, and D, but deficient in E (see abstract, this JOURNAL, Mar., 1928, p. 374). Two commercial varieties of clams were used, *Mya arenaria* or "soft-shell clam" and the *Venus mercenaria* or "quahaugs," the former obtained from the Maine coast and the latter from the lower Potomac River. Raw, frozen, hard-shell clams, fed to 50-gm. rats in 2-gm. and 5-gm. daily doses, resulted in all cases in a decline in weight, polyneuritis and death. Similar results followed the ingestion of frozen, cooked quahaugs and desiccated quahaugs. Prophylactic tests using soft-shell clams in the 5-gm. level also indicated evidence of appreciable amounts of vitamin B, which in this work refers to the vitamin B complex without reference to its separate factors.

In attempting to cure experimental xerophthalmia, quahaugs were fed at 4 levels, 1, 2, 3.5 and 5 gm. Five gm. cured xerophthalmia completely but did not prevent slight reoccurrences. With the soft-shell clams, daily doses of 3.5 gm. rapidly improved the xerophthalmic rats, the 5-gm. level being adequate for a cure and indicating some superiority in vitamin A in the soft-shell clam over the hard-shell clam. Vitamin D was determined by the line test method. Five gm. of hard-shell clams resulted in 10 days in half calcification and in 15 days in almost complete calcification of

the rachitic metaphases. Similar results were obtained with the soft-shell clams, which compared with the oysters indicated clams to be superior as a source of vitamin D. As a confirmation, the ash of clams was fed in doses equivalent to 5 gm. fresh clams and the calcifying effect in 10, 15 and 20 days was practically negligible, warranting the conclusion that the antirachitic activity is due to vitamin D and not to superimposed phosphorus. Dried, cooked hard-shell clam meats were fed as a meal to determine the reproduction and lactation factors. This experiment was conducted through two generations, in both of which the rate of growth was satisfactory. Better results were obtained in the second generation rats, in which 82 per cent of the young were reared, as against 61 per cent in the first generation. On the same basal diet with oysters only 14 per cent of the young were reared and in the second generation none was reared, warranting the conclusion that clams are superior to oysters in the reproduction and lactation factors.—D. Breese Jones, E. M. Nelson and J. C. Murphy, *Indust. & Eng. Chem.*, 20: 648 (June), 1928.

The Possibility of Producing Iodized Milk—Although figures for the iodine content of milk are given by various investigators, Forbes and others at the Ohio Experiment Station do not find iodine in milk of cows fed at the station. Milk from cows on a variety of rations and at different stages of lactation has been analyzed. In order to determine if the feeding of iodine to cows would increase the iodine content of the milk, certain cows were given potassium iodide fed in minimum amounts in order to avoid possible deleterious effects. Four cows for one complete lactation period received 0.1 gm. daily of potassium iodide equivalent to 0.08 gm. (1.2 gr.) of iodine. Six other cows received potassium iodide for varying lengths of

time. Iodine was found in the milk of these cows in amounts from 1 part in 100 million to 1 part in 10 million. This is only a very small part of the iodine fed, indicating that there is some mechanism influencing the secretion in the milk. Tests were made on 6 cows in a commercial herd near Columbus, 2 receiving no iodine, 2 receiving 2 oz. of dulce, one receiving 2 gr. of calcium iodide and the other 2 gr. of potassium iodide per day. No iodine was found in the milk before experimental feeding. After feeding for 30 days, milk from the check cows showed no iodine while milk from 4 other cows showed iodine from 1 part in 10 million to 1 part in 100 million. The iodized milk as the result of iodine fed is not richer in iodine than milk produced in sections where feeds are naturally rich in this element. Milk with an extremely low iodine content is regarded as being equally abnormal as one with a high iodine content.—C. P. Monroe, *Ohio Agri. Exp. Station Bulletin*, 13: 153 (July-Aug.), 1928.

The Relative Stability of Vitamin A from Plant Sources—Recent reports of the stability of vitamin A in butterfat and cod liver oil have prompted this investigation as to the comparative stability of this vitamin from vegetable sources. The foods to be tested were given to 28-day-old rats which had been reduced to vitamin A depletion by a special diet. Canned tomato juice filtered through cheese

cloth was freed from oxygen by the introduction of nitrogen gas, and it was found that 7 c.c. of this juice after heating 4 hours in a flask at $97^{\circ} \pm 2^{\circ}$ were required to produce the same gain in weight as 5.8 c.c. unheated juice in daily doses. When the juice was heated to the same temperature in the presence of oxygen 7 c.c. was found to be equivalent to 5.8 c.c. unheated juice. Both tests were conducted with tomato juice of normal acidity pH about 4.82. The effect of heated tomato juice in an alkaline medium was undertaken, the filtered juice being brought to a pH of 9.2 with NaOH and heated 4 hours at $98^{\circ} \pm 2^{\circ}$ in the presence of nitrogen. After reducing the heated juice with hydrochloric acid to the normal acidity, pH 4.2, this was fed in 2 c.c. doses daily.

After 8 weeks the average weight gained was 47 gm. for a juice heated at pH 4.2 and 45 gm. for the alkalinized heated juice, indicating practically no destruction of vitamin A. In comparing the animal and plant sources of this vitamin, dried spinach leaves and butterfat in olive oil solution were respectively heated 4 hours at $97^{\circ} \pm 2^{\circ}$ under anaerobic conditions. About 20 per cent of the vitamin A in spinach and about 33 per cent in butter were destroyed in this heating, indicating vitamin A from this vegetable source to be more stable than that in butter.—H. C. Sherman, E. J. Quinn, P. L. Day, and E. H. Miller, *J. Biol. Chem.*, 78: 293 (July), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

The Prevention of Maternal Mortality—The problem of maternal mortality is one which is attracting the attention of the laity as well as of the medical and nursing professions. It apparently has always been of especial interest to women members of the Labor Party in various countries. As might perhaps be expected, more stress is laid by the laity on "maternity benefits" in the shape of financial and other aid than would be the case with those trained in the science of "public welfare."

In England recently the Standing Joint Committee of Industrial Women's Organizations prepared a report for the National Conference of Labour Women. The recommendations of this committee ought to be of interest to public health and social workers in any country. American readers should, however, bear in mind the English background of Insurance Act and "doles" in any criticism offered of some of the committee's suggestions set forth below:

1. It should be compulsory for every health authority to prepare within a given time, say one year, a complete scheme for maternity work. . . .

2. Such a scheme should include the following:

(a) Sufficient ante-natal clinics to enable all pregnant women to seek advice. . . . We think that these clinics should all be organized and controlled directly by public health authorities, instead of some being under voluntary agencies. . . .

(b) Sufficient maternity beds . . . for all women whose confinements are likely to be difficult or whose home circumstances make confinement at home unsuitable and dangerous. Such provision should not be associated with the Poor Law, and should be free where necessary, with a rising scale of reasonable charges based on income. . . .

(c) National health insurance. We are in

favour of the extension of medical benefit to the wives of all insured persons and the administration of that benefit by the local health authority. This should include medical attendance and nursing care in pregnancy and childbirth free of all additional charge. . . .

(d) Sickness benefit.

(e) Maternity benefit.

(f) The provision of home helps to assist the mother in her housework both before the child's birth and in the period following is essential.

(g) Provision of food. It should be the business of the local authority, on application from its health visitors, clinics, and the doctors and midwives, to make provision for food for mothers in need of it free of cost, and at cost price for those desiring to pay.

(h) There is need for a great reorganization of medical, midwifery, and nursing services.

(i) The Medical Service must work in closest coöperation with the ante-natal clinics and maternity homes and hospitals.

(j) Where the patients are not themselves able to provide the necessary sterilized outfits, these should be provided for the use of doctors or midwives free of cost.

3. We think that there should be an inquiry into every death from puerperal causes.—

The Prevention of Maternal Mortality, Med. Off., 14 (Apr.), 1928.

Child Guidance Clinics—"Child guidance clinics do not include all child guidance work; child guidance is the responsibility of a whole community, not of just one agency." With this sound statement, Stevenson begins his discussion of the problem a community faces in deciding whether or not it ought to have such a clinic.

The first step, the author feels, is to restrict and define the meaning of the term "Child guidance clinic." He would keep it for a clinic "that uses a combination of psychiatric, psychological, and social work technics as applied to the diagnosis and treatment of the

behavior problems of children, for the most part of normal intelligence." Such a clinic has to do with all the children of the community, not merely the dependent ones. Unless the community feels this, it is not ready for a child guidance clinic. Again, the community must not look to such a clinic to "take the troublesome children off its hands." It cannot be done if for no other reason than that of numbers.

"The big job of the clinic," according to Stevenson, "is the education of a community in matters of mental health and the mobilization of its resources to this end." Furthermore, the clinic works largely through other professional groups rather than through parents and children.

A community is not ready for a child guidance clinic until: (a) it has a small intelligent group interested in child guidance work who will educate a still larger group; (b) well-developed social work is available; (c) there are good court facilities for handling the social problems of child and adult.

Finally, suggestions are offered communities unable to have a child guidance *clinic* whereby they may carry out child guidance *activities*. The points enumerated are: trained psychiatric social work; special instruction and classification in the school system under an educational psychologist; provision for local diagnosis and care for the feeble-minded; vocational training classes in the public schools; coördination of school and preschool general medical clinics.—George S. Stevenson, M.D., *When Is a Community Ready for a Child-Guidance Clinic?*—*Mental Hyg.*, July, 1928.

Prenatal Care vs. No Prenatal Care—The study under review was made at the prenatal clinic of the Louisville City Hospital, associated with the obstetrical department of the University of Louisville Medical School, and

covered all cases treated in the obstetrical department of the hospital for a given length of time. All deaths, maternal and fetal, were included, whether from obstetrical causes or not, on the theory that prenatal care is expected "to protect mothers and babies from all danger, medical, surgical or obstetrical, which may arise during the prenatal period."

A general physical examination was given all patients, which included pelvic measurements, blood pressure reading, urinalysis and Wassermann test. Patients came to the clinic at intervals of two weeks for the first seven months, and one week during the last two months of pregnancy.

In recording the deaths, there were included patients practically moribund on admission. Neonatal deaths, that is, those occurring during the first two weeks of life, were also charged up to the obstetrical department in this study.

The results were as follows: There were 3,217 mothers delivered during a period of something over 4 years. Of these, 2,061 had one or more prenatal visits. The rest—1,156—had received no prenatal care. That is, about two-thirds had and one-third had not prenatal care. The maternal death rate among the prenatal clinic cases was 2.91 per 1,000 deliveries as compared with a rate of 22.4 among mothers not getting prenatal care. As regards fetal deaths, the rate was 7.5 per cent among clinic patients as compared with 22.6 per cent among non-clinic patients.

One other point is of great interest. With respect to "eclampsia," the record was 0.58 per cent cases and no deaths among those attending the prenatal clinic; and 3.02 per cent cases and 8.6 deaths per 1,000 deliveries among the non-clinic patients.—Alice N. Pickett, M.D., *A Study of the Results of Prenatal Care vs. No Prenatal Care*. Read before Kentucky State Medical Association, Oct., 1927 (Reprint).

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Keep This in Mind—Public health nurses attending the Annual Meeting of the American Public Health Association in Chicago, October 15 to 19, will have the privilege of studying at close range the methods used in conducting a nursery school. The Franklin Nursery School, which is established and maintained by the Elizabeth McCormick Memorial Fund in cooperation with the Institute for Juvenile Research, will serve as a model.

Visits to Infant Welfare Stations and the various centers of the Chicago Visiting Nurse Association will also be included in the nurses' program.

Breaking Faith with the Indian—“Breaking Faith with the Indian,” an article in *The New Republic*, calls attention to the conditions in the reservations which cry out for improved public health service, reading in part:

Indian education as a whole can only be called a failure

Indian health is much inferior to that of the whites. The general and infant mortality rates are both very high, though statistics are kept so badly that it is impossible to say just how high they are.

The Indians live under conditions of great overcrowding, with inadequate ventilation and sanitation. It is not even possible to segregate those suffering from communicable diseases.

Many of the Indians live on land so poor that it is hopeless to expect them to make a living from their efforts as farmers, even if the government properly assisted them to do this, which it does not. . . .

The whole Indian service suffers because of the fact that salaries of administrators are too low. It is impossible to get good men more than temporarily for the remuneration offered. This is particularly true of the doctors, nurses and teachers. These low standards may account for the fact that in the treatment of trachoma, for example, no attention is usually paid to modern discoveries as to the relation

of the disease to insufficient diet, but recourse is had to a radical operation. This operation has been performed in many cases when it was unnecessary, including some in which the patient did not have trachoma at all. In one special school for children suffering with trachoma, the normal diet actually includes no milk. Everywhere, there is an insufficiency of milk and of fresh vegetables. . . .

New positions in the field of health, economic advancement, education and social development should be created, and salaries fixed which are high enough to attract competent persons. Public health clinics for the Indians are urgently necessary, particularly in the struggle against the two most prevalent diseases, trachoma and tuberculosis. D. D.

The Interrelations of the Hospital Social Service Departments and the Community Health Association of Boston—One of the fundamental premises of health or social workers in any field is that health, economic security, harmonious relationships with the family and society, balanced living, all are interdependent and indispensable factors in the full free life of the individuals for whom their work exists. In order to consider all these factors in working for the welfare of their clients or patients, the special workers in any one field of social work must and do use the services of other groups. Most particularly do hospital social workers and visiting nurses depend upon each other.

However, in the pressure of work and the intensity with which each group has been developing and changing during the past twenty years, there has been little time for directed effort toward knowing each other's functions or considering the best methods of working together.

With the view of securing a better

working partnership between the hospital social workers and the visiting nurses of the Community Health Association of Boston, a study of their relationship has been made during the first part of this year. The survey was made by Mrs. Hilbert Day, with the assistance of a committee made up of representatives of the two groups. The final report of this survey has recently been printed, and its findings and recommendations are probably sufficiently applicable to other communities so that it may be of interest to readers of this JOURNAL.

The study was conducted by means of interviews, letters and case studies, gathered together over a period of about three months. On the whole, both interviews and case studies have resulted in repeated affirmations of good co-operation between the two groups, and tolerance toward some of the inevitable difficulties. In about 15 per cent, or 168 of the 1,000 case studies, relationships were considered by the nurses to be unsatisfactory for one reason or another, and the social workers made a few general criticisms of the nurses' methods of work. Since each unsatisfactory case represents inefficient service to the family, and is a potential cause of ill feeling which reacts upon future relationships, and since there is every indication that the interdependence of the two groups is to become more important as time goes on, it seemed to the committee wise to try to analyze and, if possible, suggest corrections for the underlying difficulties in these 168 cases.

The causes for unsatisfactory coöperation fell into a few definite groups:

1. Conditions which cannot at present be altered, but which by recognition and understanding can be greatly minimized:
 - A. Insufficient number of hospital social workers
 - B. Unavoidable turnover of nurses on a case

2. Mechanical details which can probably be remedied:

- A. Variations in methods of referring cases, and inadequate information given about cases
- B. Lack of uniformity as to what cases shall be accepted as social cases by hospital social workers
- C. Undetermined policy as to responsibility for social follow-up in individual cases
- D. Difference between the two groups in the "time standard" for action on a case
- E. Lack of routine methods in Social Service Departments for securing medical information and orders for the use of the nurses
- F. Poor administration of certain accepted routine procedures

3. Elements not fully perceived or used:

- A. The Community Health Association nurses have an intimate and useful fund of knowledge of family conditions of many patients, due to many illnesses or long contact with the families
- B. Opportunity for further use of the Community Health Association for group services to patients, as is already done in classes for prenatal patients
- C. Complementary nature of the professional education of the two professional groups, if rightly utilized

Since the fundamental strength of the relationship of the two organized groups is dependent upon understanding, it is recommended that:

- A. A continued process of education be considered by:
 1. The addition to the training of students in the School for Social Work and the School of Public Health Nursing of a short period of observation in the work of the other group
 2. An exchange of workers between the two groups for short periods of observation
- B. The conference method be used for discussion of problems mentioned above
- C. Case conferences be held to discuss such difficult cases as involve the intensive work of both groups
- D. A social case worker be considered as a consultant on the staff of the Community Health Association.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Help on Your Job at Chicago—
The section meetings, the Education-Publicity Headquarters, the contacts with those concerned with public health education *should be of real, definite, practical help in doing more and better work.* And of course you have ideas and information of value to the other fellow.

Professional and Lay Coöperation
—The coöperative promotion of the health examination idea by the Medical Society, County of New York, and the New York Tuberculosis and Health Association in a Joint Campaign is told in a reprint from *The Physical Examiner* of an article by Iago Galdston, M.D. Since the procedure and educational material are available through free copies of the reprint, it is sufficient here to urge every health worker interested in the subject to request a copy from the New York Tuberculosis and Health Association, 244 Madison Ave., New York, N. Y. (See exhibit at Chicago.) 3 cents postage.

"An Important and Worthy Object"—A leader in the field of psychiatry said:

May I add to this statement a conviction that I have for many years maintained, namely, that in efforts to get over what we possess to these others that we should undertake the task not as a task that is beneath us but as one well worthy of our metal. The task of popularization, as it is generally called, is too often conceived to be unworthy of the scientific man, but as Professor Robinson has said, in substance, the getting over of the results of scientific inquiry to the public, or at least to that portion of it who can and who ought to know

about them and use them, is as important and worthy an object of scientific research as the discovery of new scientific facts. In fact it is itself a problem in the realm of methodology and should be so considered. In the past I am sure we have erred very seriously by presenting our material in a way that activated the resistances of our audiences.—

Dr. William A. White, *Psychoanalytic Rev.*, Apr., 1928. (Contributed by Paul Komora of National Committee for Mental Hygiene.)

At Every State Convention—At every state health convention and every state conference of social work there should be enough delegates interested in public health education to call a luncheon conference. One plan: ask each one present to state one question he would like to have answered. Then the group present will select the questions to be taken up at the luncheon. Appoint a small committee to plan another luncheon next year. Please write to Prof. John Sundwall, Lansing, Mich., to state that you will arrange for such a luncheon session this fall or winter.

Never Too Late to Learn—"The long and short of it is that modern psychology has demonstrated that for practical purposes age is only a minor handicap, if any at all, to learning anything you want to learn or need to learn." So says Albert Edward Wigam in *Good Housekeeping* (Sept., 1928), in "It Is Never Too Late to Learn," a popular discussion of recent studies by Thorndike and others. Our job is twofold: first, to cultivate the *will to learn*, and second, to learn a lot more ourselves about how to teach health to adults.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Stimulating Advertisements—Numerous advertisements in magazines and elsewhere should suggest types of headings for folders and booklets, and ways of developing practical health education material leading away from the conventional practices of health workers. Examples: "I *just couldn't* afford to be laid up"; "Little adventurers! New, better ways to guide them"; "100 per cent of her pupils gained in weight!"; "So many things you do for them—which will count most in the years to come?" and "Beauty Wins—Beauty Keeps" in *Good Housekeeping*, Sept., 1928.

A Simple, Popular Service—Scales in the City Hall! Why not? Make an event of installing the scales by weighing the mayor and other officials. Then a week or two later extend a formal invitation to all citizens to use the scales, inviting several leading citizens to start the idea. Of course, you will let the newspapers know in advance so that photographs may be taken. Height and weight tables can be displayed near the scales.

EXHIBITS

"Classroom Display Settings," by E. A. Deuch, *Infants' and Children's Dept.*, 323 West Jackson Blvd., Chicago, Ill. Probably *free*. Illustrations and text offer ideas adaptable for window display of child health. The large blackboard in the background gives the health opportunity.

Publishers' Weekly tells of a large grandfather's clock in a book store window. "Although it was regularly wound up and kept time correctly, a sign above the clock informed passersby that 'This is not the right time.' Many people naturally stopped to make sure, and on looking more closely they found a smaller sign at the foot of the clock which read '—to be neglecting your education.'" Change the copy to read

"—to be neglecting your health examination"—or what you will.

"The Retail Grocers' Association of Syracuse has voted to coöperate with the department of health in the grocery store exhibits for the current year. Its coöperation is to express itself: (1) by carrying the exhibits from one store to the next; and (2) by printing a leaflet to accompany each exhibit emphasizing health and nutrition lessons."—*Better Health*, Syracuse Dept. of Health.

A truck in a safety parade carried these legends: "The Chance Taken Is an Accident Maker"; "What Do I Care about Safety? Look Who I Am?" On the truck was a donkey!—*Public Safety*, 108 East Ohio St., Chicago, Ill., Apr., 1928. *Free*.

POPULAR ARTICLES

"Decay of the Teeth Is Found Preventable." *New York Times*, Apr. 1, 1928.

"Feet Made to Fit Shoes or Stockings." *Press Bull.*, University of Wisconsin, Madison, Wis., Aug. 29, 1928. *Free*.

"It's the Timidity," by Ruth F. Wadsworth, M.D. *Collier's Weekly*, July 28, 1928. "Most of the things we can do to attain at least the feeling of being cool most of us are convinced are bad for us." File this for next summer's use.

"Prolonging Life." Editorial, *Sat. Ev. Post*, June 16, 1928.

ANNUAL REPORTS

The annual report of the State Charities Aid Association of New York, "Milestone 55," has 116 large book size pages, reporting in considerable detail on a wide range of activities. But the report largely avoids the appearance of being dull and heavy via good margins,

short paragraphs, sub-heads and type size. A table of contents (no index); arranged in "chapter" form; few statistical tables; extensive staff and committee lists and financial report *in the back pages*.

If you are studying annual reports ask the local associated charities to see copies of these reports: Hartford C.O.S. (how the cases are classified on page 3), Family Society of Philadelphia (for tabbed-in photographs; and general layout—though it lacks sub-headings); Cleveland A. C. (for picture map showing districts and activities; in copy and plan it is a gem, except type is too small).

Report of Maternity Center Association, 578 Madison Ave., New York, N. Y., illustrates striking use of color in diagram and map.

"Are You Satisfied with the Annual Reports You Receive?" by Marguerite A. Wales, *Public Health Nurse*, Apr., 1928. "The trend in content of reports during the past few years should hearten even the pessimist."

WORDS

"The Importance of Respiratory Diseases as a Cause of Disability among Industrial Workers(!)." A radio talk.

DIPHTHERIA

In a report of the June, 1927, meeting of the Tri-state Medical Conference, are interesting reviews of the participation of state and county medical societies in Pennsylvania, New York and New Jersey. *Atlantic M. J.*, Harrisburg, Aug., 1927. 35 cents.

Dr. D. S. Dooman, health officer and school physician of Garden City, N. Y., having found confusion in the minds of some parents to whom consent slips for toxin-antitoxin were sent, forwarded a questionnaire to the parents of every child in the Garden City schools. The questions covered whether the child had T. A. T. from the family physician or

otherwise, and whether the parents were willing that the inoculations be given at the school. "Within 72 hours we had a record of every child."—The full questionnaire in *Health News*, State Dept. of Health, Albany, N. Y., Dec. 26, 1927. *Free*.

"The best birthday gift to your child is a certificate of protection against diphtheria. Your child should receive Diphtheria Toxin-Antitoxin before his first birthday."—*Sanitary Bull.*, Buffalo Dept. of Health.

Detailed account of Philadelphia's diphtheria campaign, with reproductions of educational publicity material. *Monthly Bull.*, Philadelphia Dept. of Health, July-Aug., 1928.

Application to diphtheria of preventive spraying against insects in a rural community in "Calhoun County Starts Fight on Diphtheria." *Ill. Health News*, State Dept. of Health, June, 1928.

Diphtheria—Its Prevention and Control. By U. S. Public Health Service. 20 pp. *Revised*. Supt. of Documents, Washington, D. C. 5 cents.

NEWS POSSIBILITIES

Check up on the "best sellers" in the health field at book stores, and the "best lenders" at the public library. If the leaders are of the right sort you have a minor newspaper story, and you may glean something as to health questions in which the public is interested. If the wrong books head the list you have data for consideration in planning your year's program.

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

Milk and the Courts—There are on record in this country about 175 decisions of courts of last resort on the subject of milk. In 1924 an endeavor was made for the first time to compile a complete list of these decisions, and 121 reported cases in 32 state and federal courts were assembled by the associate editor, and listed by states at the end of an article on the legal aspects of milk, which appeared in *Public Health Reports* for July 18, 1924. This was later issued by the U. S. Public Health Service as *Reprint No. 939*. Court decisions dealing with pasteurization requirements were discussed in *Public Health Reports* for July 1, 1927, and this article has been published as *Reprint No. 1168*. A paper summarizing court decisions on milk during the year 1927–1928 was read before the meeting of state health officers at St. Paul in June, 1928, and will be published later.

The most complete and useful enumeration of court decisions on all phases of control of milk appeared in *Public Health Reports* for August 10, 1928, in connection with an article on "Regulating the production, handling, and distribution of milk," by Harvey Walker, Acting Secretary of the League of Minnesota Municipalities. Mr. Walker's article consists of a restatement of the legal principles which apply to milk regulation. Appended to this is a comprehensive annotated list of about 150 court decisions, arranged according to topics, of which there are 32. Mr. Walker's list includes the court decisions on milk which have been reported since the earlier article appeared in 1924, as well as a considerable number of others not included there. On the other hand,

the 1924 material cites about 25 decisions not given by Mr. Walker.

The references compiled by Mr. Walker are unusually complete. Not only is the date of each case given, but there are citations to all of the different law reporters in which each decision may be found. The assembling and arrangement of these court decisions is a notable contribution to public health law, one which will be of great value to sanitarians in administrative positions.

Law and the Conservation of Vision—School laws requiring vision tests to be made as part of the medical inspection program or as special tests have been a distinct factor in the effectiveness of work for the conservation of vision, according to the revised edition of a pamphlet entitled "Conserving the Sight of School Children," prepared under the direction of Dr. Thomas D. Wood for the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association. The provisions of the various laws differ greatly, however, and the report accordingly urges the preparation of a uniform model law for the examination of the eyes of school children, which might be adopted in all states. A copy of this valuable pamphlet may be obtained from the National Society for the Prevention of Blindness, New York, N. Y., or through the book service of the A. P. H. A.

Nearly one-half of a group of approximately 2,000 school children examined were found to need glasses, according to a news release issued by the U. S. Public Health Service under date

of September 4, 1928. These results of a typical group may be taken as representing conditions in the general school population of the country, according to the Service.

The adoption and enforcement of laws requiring physicians, midwives, and other attendants at birth to put prophylactic drops in the eyes of babies at birth has resulted in a decline of 64 per cent in the frequency of ophthalmia neonatorum as a cause of blindness among those admitted to schools for the blind, according to a recent news release from the National Society for the Prevention of Blindness.

Protective eyeglasses for industrial workers are described in a pamphlet issued in August by the U. S. Bureau of Standards, Washington, D. C., after, it is said, ten years of research.

Liability of City for Water-borne Typhoid—The courts recognize that the purity of water is of great importance to public health. As was pointed out in this department in the June issue, it now seems to be well-settled law in this country that a municipal corporation, while not an insurer of the purity of water supplied by it, may be, nevertheless, liable for negligence in furnishing water which causes disease. The city must exercise reasonable care to secure and maintain the purity of the water. This doctrine has recently been upheld by the Appellate Division of the Supreme Court of New York, and the July issue of the *Indiana Monthly Bulletin* contains the information that a Circuit Court in that state has recently awarded damages of \$9,000 against the City of Fort Wayne and the Pennsylvania Railroad, because of a death from typhoid due to bad water from the railroad's industrial supply which got into the city water.

The New York case, *Wiesner vs. City of Albany*, 229 N. Y. S. 622, is of interest not merely because it sustains the

legal principle, but also because of the holding with respect to the adequacy of the evidence needed to prove the injury. From a copy of this decision, which has been sent us by B. R. Rickards of the New York State Department of Health, it appears that a 7-year-old child contracted typhoid fever from the city water, which was taken from the highly polluted Hudson River. Tests of this water prior to the development of this case were made by an employe of the State Department of Health, who found colon bacilli, an evidence of human contamination.

Notice of this fact was sent to the city officials, who also knew of the presence of a defective conduit, and were aware of an unusual prevalence of gastrointestinal diseases in the city. "It was a time for prompt and decisive action," said the court in its opinion. "The exercise of vigilance would have led to discovery of the dangerous condition, and reasonable diligence would have provided the remedy."

These events occurred in April. In May there were 83 cases of typhoid of local origin. The plaintiff in this case offered proof pointing to the city water as the cause of the disease and excluding other sources. The city argued that there were other possible sources, but proved none. In its able opinion, the court said:

To insist that the plaintiff must establish that the infection came from the city water by positive proof would be to require an impossibility. It is sufficient if it is shown by the best evidence available that the bacilli were introduced into his system by means of the city water, so that the jury may by reasonable inference reach a conclusion to that effect. This is not speculation, but a process of logical deduction (*Forbes vs. City of Jamestown*, 212 App. Div. 332, 335; s.c. 217 Id. 714). If the plaintiff is able to establish facts from which it can be said with reasonable certainty that the direct cause of the injury was the one for which the defendant was liable, a more stringent rule will not be applied to his case and the jury will be permitted to say that they are satisfied with the proof made, and to de-

termine therefrom the source of infection was the polluted water (Stubbs vs. City of Rochester, 226 N. Y. 516, 526).

This case is also abstracted in *Public Health Reports* for August 10, 1928 (page 2114), the same issue containing the court decisions on milk control referred to above. A reprint on the legal liability for water-borne typhoid may be obtained from Wallace & Tiernan Company, Newark, N. J.

A Sanitary Engineering Section at Washington—Effective July 1, 1928, a sanitary engineering section has been organized in the Domestic Quarantine Division of the U. S. Public Health Service, according to a circular letter sent out by the Surgeon General on August 10. This arrangement "will serve to coördinate the engineering activities of the domestic quarantine division and make practicable their detailed supervision by a sanitary engineer of broad experience." One of the immediate effects is the combination of shellfish sanitation work with that of the interstate sanitary districts, the headquarters of which are now at New York, Washington, Chicago, Memphis, and San Francisco.

An article regarding the organization and work of the U. S. Public Health Service, by Surgeon General H. S. Cumming, appears in *The Trained Nurse and Hospital Review* for August, 1928. This same issue has a poignant editorial captioned "A Regrettable Veto," dealing with the Parker Bill as it affects nurses. The disapproval of this excellent measure by President Coolidge is disapproved.

Minnesota's Health Laws—About 100 pages are now required to present the health laws and regulations of Minnesota. A new pamphlet compilation of this legislation, together with ap-

propriate opinions of the attorney general, was issued under date of February 15, 1928, by the Minnesota State Board of Health, of which A. J. Chesley, M.D., is executive officer. This pamphlet, superseding a 1924 edition, is well arranged, well printed, and has an excellent index, always a most important item in such works. If annotations to useful court decisions had been included, this book would have been even more valuable. State health departments which do not do it should issue regularly new editions of their state health laws and regulations.

The Presidency and Public Health—In their speeches of acceptance each of the candidates for election to the Presidency of the United States made brief reference to public health. This is what Herbert C. Hoover had to say, as reported in the *New York Times* for Aug. 12, 1928:

For many years I have been associated with efforts to save life and health for our children. These experiences with millions of children both at home and abroad have left an indelible impression—that the greatness of any nation, its freedom from poverty and crime, its aspirations and ideals, are the direct quotient of the care of its children. Racial progress marches upon the feet of healthy and instructed children. There should be no child in America that is not born and does not live under sound conditions of health. . . .

The remarks by Governor Alfred E. Smith, as given in the *New York Herald Tribune* for Aug. 23, 1928, are as follows:

I shall continue my sympathetic interest in the advancement of progressive legislation for the protection and advancement of working men and women. Promotion of proper care of maternity, infancy and childhood and the encouragement of those scientific activities of the national government which advance the safeguards of public health, are so fundamental as to need no expression from me other than my record as legislator and as Governor.

BOOKS AND REPORTS

The Validity of the Appraisal Form as a Measure of Administrative Health Practice—By Philip S. Platt, C.P.H., Ph.D. New York: American Public Health Assn., 1928. 102 pp. Price, \$1.50.

A well-written, interesting, and carefully and scientifically prepared volume which should be read by all who have any interest in public health administration. It would have been very difficult to find a man better qualified to discuss the *Appraisal Form for City Health Work* than Dr. Platt. His field experience in surveying cities using the Appraisal Form, together with subsequent years of intensive study of the form and its uses, gives authority to the work. [The study was made largely at the instigation of the Committee on Administrative Practice of the American Public Health Association, which committee developed and published the *Appraisal Form for City Health Work*.] It is the only intensive and authoritative work thus far published on the present status of city health appraisal and has been and will continue to be of inestimable value to the Committee on Administrative Practice in discussing the revision of the Appraisal Form.

In addition to an Introduction, in which the author describes the purpose of the study, its characteristics and the collection of data, the volume contains 5 chapters devoted respectively to the Description of the Appraisal Form, Analysis of the Health Activities of the 46 cities, Validation of the Appraisal Form as a Test, Construction of the Abridged Appraisal Form, and Changes in the Appraisal Form.

As the name of the volume implies, to quote the author, "the purpose of the study is to determine whether adminis-

trative health practice as developed today in American cities can be objectively measured in a reliable and valid manner by such a measuring device as the 'Appraisal Form for City Health Work.' "

Before attempting to prove or disprove the reliability of the measure we must clearly understand what it is attempting to measure. The purpose of the Appraisal Form "is primarily to measure the extent of development of administrative health procedures and activities, public and private. It is not a measure of the effectiveness of the activities themselves, nor of the effectiveness of the public health program as a whole. It is not primarily a measure of quality of work *per se*, although indirectly quality of work is measured to a considerable degree."

There is a brief description of the history of the appraisal form idea preceding a full discussion of the development of the present Appraisal Form with its division into 11 major health activities further subdivided into 131 individual items or criteria. The author calls attention to the continual emphasis, on the part of the committee in developing the form, of the necessity of arriving at criteria, standards, and values as the result of group judgment rather than individual opinion. He likewise points out that relative values were finally fixed "from the viewpoint of the relative importance of the criteria in a well-rounded health problem as understood and developed today, not from a consideration of their absolute or potential values in preventing sickness or death."

Following a careful and comprehensive analysis of the surveys of 46 cities, the Appraisal Form as a test is discussed as to its objectivity, reliability

and validity. The general conclusions are that only 6 of the 131 criteria are likely to be sufficiently affected by differences in judgment as to class them as non-objective, that where two or more persons have been engaged in the survey of a city a divergence of opinion as to the scoring of criteria is rare, and that where a city has been re-appraised by a second individual there is a very close correlation between the two appraisals. Taking the 131 criteria and dividing them into two groups, the odd criteria being placed in one group, the even in another, and comparing the scores of each city for the two groups, there is found to be a high correlation which indicates good reliability, in that one-half of the test is practically as good as the other half. The validity of the form is shown by the close correlation which exists between the ranking of cities on the basis of scores obtained, on the one hand, and the opinion of persons having knowledge of the health practices in these cities when both are arranged in order as 1, 2, 3, etc.

The author has constructed what he terms an "Abridged Appraisal Form" based on an analysis of those criteria which best represented the major activities of which they are a part. This form represents the 11 major health activities of the longer form and contains in all 22 criteria. The correlation between scores obtained with the official form and this abridged form showed a very markedly close correlation. Such a form may well be used to make a hasty preliminary appraisal and to predict the probable result when the official form is used. It should not be used as a substitute for the Appraisal Form itself for one of the chief values of the longer form is that it makes the user think of the relationship between the various component parts of the health program.

In discussing changes the author points out the fact that the Appraisal Form has been constructed with the

idea in mind of revising it from time to time as better standards and values may be worked out, and more important still, as new public health activities become generally accepted.

The entire volume is thoroughly scientific in its approach, is well illustrated with tables and figures and deductions so carefully made that we may accept with confidence the author's conclusion that the "study has produced evidence to show that, so far as can be judged at present, the principle of the Appraisal Form is sound, and its application is practicable and reliable."

The typography and make-up of the book make it readable and attractive, and the paper has been chosen to add to its appearance

CARL E. BUCK

Prohibition: Its Industrial and Economic Aspects—*By Herman Feldman, Ph.D. New York: Appleton, 1927. 415 pp. Price, \$2.00.*

One of the most difficult parts of the problem of estimating the effect of prohibition is the amassing of the real facts with reference to the use of alcoholic beverages. It is exceedingly easy to get thousands of opinions on this subject, but it is exceedingly difficult to arrive at a sufficient body of facts which, when judged by objective criteria, render the decision obvious. Dr. Feldman has written an exceedingly interesting book, as all books on this subject are. The very recital of contrasting opinions on the subject of prohibition must be of interest to the social-minded worker. However, Dr. Feldman attempted to go still farther than this, and by means of questionnaires distributed very widely by the American Management Association, secretaries of the chambers of commerce of the principal industrial cities of the United States, and by reference to various trade organizations' lists of members, coal mines, and electric railway associations, he has obtained a body of fundamental data used in arriving at

the conclusions of this study. In all, some 900,000 employes were engaged in those companies returning the questionnaires and including the concerns visited by the writer over 1,250,000 employes were entered on the pay-roll. Less than 80 per cent of these were males. The questionnaire covered the following six general topics: discharges and labor turnover on account of drunkenness; absences or tardiness because of drunkenness; accidents caused by excessive drinking; productivity and prohibition; general economic effects; and, finally, a statistical compilation covering the number of workers discharged, number of accidents and number of absences in pre-prohibition and prohibition years.

The author further attempts to answer certain other fundamental questions by reference to the available statistics on the consumption of various other beverages, the addiction to the drug habit and the change from the saloon as the Poor Man's Club, to sports, the radio and home.

The conclusion is finally reached that the advantages or disadvantages of prohibition must be judged over a long-time period, and on this basis the economic loss due to prohibition is not a serious problem. In addition to this, the opinion of the industrial employers and executives appears to be that prohibition is favorable to production. On this point, however, employers themselves admit their inability to provide sufficient data in addition to their opinions. There appears to be satisfactory evidence that prohibition has had the effect of stimulating the consumption of other foodstuffs, a change which has a vast economic importance in the opinion of the author. In conclusion, the author reaffirms his belief that the next few years will be the ones which will fix the status of prohibition, the results depending not on the enactment of statutory prohibition, but on the achievement of prohibition in fact.

LEONARD GREENBURG

Convalescence: Historical and Practical—By John Bryant. New York: The Burke Foundation, White Plains, 1927. 261 pp. Price, \$5.00.

This volume, which deals in a most interesting way with the historical and practical aspects of convalescent care, has been brought out to stimulate interest in this important but as yet little recognized phase of community health service.

The review of the literature which traces the development of convalescent care from the building of the Hotel Dieu and Charité Hospital in Paris in 1640 and 1650, shows an early appreciation, by certain leaders, of the principal requirements for rapid and successful convalescence. The best features of the retreats frequented by the wealthy after illness were incorporated in these early plans for institutions for the less fortunate. The routines of these homes for after-care show remarkable agreement with the best practices today.

The review interprets the lack of material in the literature from 1878 to 1900 as reflecting the almost complete lack of interest in the subject in this country during that period.

The author recounts interestingly the experience from various sources such as the Burke Foundation and the Army, the practices in convalescent care which have proved worth while.

The person interested will find here rather full reporting of cases and treatments. Possibly the most important chapter is that dealing with the community aspects of the question, showing a need of one bed for convalescence for every ten beds for acute condition, and it is pointed out that deficiencies in this quota are probably more serious than a slight shortage of beds for acute illness.

A hopeful note is sounded in the review of the last few years as it is stated that nearly 3,000 beds per year are now being provided in this country for convalescence.

W. F. WALKER

Der Kokainismus—By Prof. Dr. Hans W. Maier. Leipzig: Thieme, 1926. 269 pp. (22 ill.) Price, Goldmark 17.50.

In the reviewer's opinion, this is the first and only comprehensive work on the subject of cocaineism. Prof. Maier is well known in the psychiatric world as a teacher, practitioner, and writer. Having been Bleuler's right-hand man for over 20 years, he has now succeeded his chief as head of the Burghölzli Clinic of Psychiatry at Zurich.

The author starts his work with a historical description of cocaineism. He describes the use of coca leaves as a food, in the form of chewing. This custom, which is still in practice among the South American Indians, existed when the Spaniards conquered the Incas. When the Spanish conquerors tried to suppress this habit among the natives, and found it impossible, they placed a heavy tax on it. As a matter of fact, it soon became a question whether chewing of coca leaves was really harmful to the average native. Moderate chewing had its defenders even then, as it has today.

In chapters II and III the author gives a full account of how the alkaloid cocaine was discovered by Niemann of Göttingen. He then gives the detailed processes of manufacturing it for commercial use, its chemistry, its demonstration in the cadaver, and simple tests of its presence in the living person. The physiological effects of the drug are taken up in chapter IV.

A very interesting chapter in the cultural history of medicine is chapter V, wherein the author gives the history of the development of cocaineism and its geographical dissemination since its discovery and use in medicine. The most interesting part to the reviewer is the author's description of Prof. Freud's experiments with cocaine, which he began in 1883. The introduction of cocaine as a local anesthetic in ophthalmology, by

Koller, was largely due to Freud's works.

The evil effects of cocaineism soon became apparent. The author quotes an editorial to this effect, from the *New York Medical Record* (May 29, 1886), showing that we kept abreast with Europe in this respect. Numerous reports of cocaine poisoning appeared everywhere. Psychotic states, resulting from chronic cocaine ingestion, were first reported by Magnan, in Paris, in 1889.

Chapter VI treats of the effects of cocaineism on man. The author states that snuffing is the most frequent way of taking cocaine since 1915. The physical as well as the mental symptoms given by various writers are thoroughly described.

Among the special symptomatology, Prof. Maier discusses acute and chronic cocaineism, subacute cocaine deliria, the cocaine delusion, etc., citing many interesting clinical records.

The material upon which Prof. Maier based his observations consisted of one hundred cocaine addicts observed by him, and of some case histories from other Swiss psychiatric hospitals. The male sex shows a greater representation in cocaineism in Switzerland, as well as in Italy. "The treatment," the author states, "must be extremely individual. Every case has its own peculiarities. To get to the root of the evil, it is therefore necessary to make a thorough psychic examination." Prof. Maier gives a full account of the methods of procedure in the treatment of acute and chronic cocaineism.

Chapter VII discusses cocaineism as a social danger, the legal way of combating it by international paths, in which he shows the progress made so far, the countries participating in it, and the methods adopted.

It is unfortunate that this work is not available to English-speaking readers. The reviewer hopes that an English translation will soon be made.

A. A. BRILL

Feeding the Child from Two to Six
—*Mary Frances Hartley Barnes.*
New York: Macmillan, 1928. 206
pp. Price, \$2.50.

This book fills a real need. It puts into practical form the essentials of dietary selection and preparation for the "runabout" ages. The author has faced the real problems of feeding children at home and in camps and institutions. She has eliminated the confusing nonessentials and put in the language of the average parent those facts about food and feeding upon which the various authorities agree. Such a contribution should be helpful to doctors, nurses, social workers and home economics students as well as parents. The references to constipation, malnutrition and certain psychological problems are merely given to suggest the common aspects of these conditions which are related to food—there are of course other causes at work in many such cases. The author appears to regard the appetite as a rather reliable guide to the quantity necessary at each meal for children who are to be kept healthy, instead of insisting upon a mathematical caloric total, and in this belief she has the support of the reviewer.

LEROY A. WILKES

How to Cook for Children—By
Estelle M. Reilly. *New York: Putnam, 1927.* 245 pp. Price, \$1.75.

Children these days are claiming their share of attention from nutritionists. A mother of six children has prepared a book for other mothers, based on her own experiments and the findings of psychologists, pediatricians and nutritionists. In chatty style the author analyzes the values of various foods, tells mothers how to select foods for their children and how to prepare them. Menu suggestions for the child from 18 months to 3 years are given in addition to the menus for normal healthy children over 3 years of age. A feature of the

book that will help the mother who is so often perplexed about the birthday party for the runabout is the party menu for hot or cold weather. The book will whet the food imagination of any mother who is struggling to combine nutrition principles and attractive varied daily menus.

Nutrition—By *Walter H. Eddy.*
Baltimore: Williams & Wilkins, 1928.
223 pp. Price, \$2.50.

What comprises a complete food, what foods we need, how much we should eat, and the story of vitamins from their discovery through their analyses, and how they function, is told to the layman in a language free from technicalities. Professor Eddy has done much by his writings to familiarize the housewife with the scientific findings of the nutrition laboratory and the mother who aims to be intelligent in regard to the health building of her family can profitably add this to the home library. Business people, too, would be influenced in the selection of their foods by a reading of this book.

The Health and Happiness Series—

By *S. Weir Newmayer, M.D., and Edwin C. Broome, Ph.D., LL.D.*
New York: American Book Co., 1928.

Book I. The Play Road to Health.
144 pp. \$.64.

Book II. Health Habits. 207 pp.
\$.72.

Book III. The Way to Keep Well.
264 pp. \$.84.

Book IV. The Human Body and Its Care. 314 pp. \$.96.

In the first book of the series health is dramatized for the very young children and in the succeeding titles, health habits, personal hygiene and keeping well, and the hygiene of individual and community are emphasized. This series has been prepared as supplementary reading work and as aids to the school health education program.

Labor Protection in Soviet Russia—

By George M. Price, M.D. New York: International Publishers, 1928. 128 pp. Price, \$1.25.

This small but exceedingly interesting book presents a very logical story of the development of labor conditions in Russia from about 1860 to the present time. It is based on three visits of the author in 1913, 1922 and 1927 to Russia, during which times he was enabled to study the conditions of labor in great detail. The book is plainly a statement of fact obtained on the occasion of these visits, and to one who is interested in the improvement of labor conditions and the development of this aspect of the social program it is a very important and succinct document.

The industrial hygienist will find much to interest him in this volume, and, judging by the progress made in Russia during the past few years along these lines, there remains much hope for major contributions from this country.

LEONARD GREENBURG

Bulletin of the Maryland State Department of Health—Vol. 1, No. 3, April, 1928.

This publication is the third of this nature presented by the Maryland State Department of Health. It strives to make public the more interesting and outstanding engineering studies and reports of that department.

The first two papers are concerned with shellfish. The data compiled in the one describing the oyster findings in Chesapeake Bay and its tributaries by investigations conducted from March, 1925, to January, 1927, are particularly useful at this time when the status of shellfish investigational results is still unsettled.

Two papers by Wolman, one on rational water consumption and another on the rôle of iron in the activated sludge process, are well worth reading.

Sewage treatment receives a fair proportion of space. Schaetzle has presented by himself and in collaboration with others three good reports, one on tannery waste treatment, another on the effect of liquid chlorine application to trickling filters, and a third covering observations on sludge digestion at a small treatment plant.

The last 37 pages of the pamphlet give the proceedings of the First Annual Conference of Maryland Water and Sewage Plant Operators.

ARTHUR P. MILLER

Public School Plumbing Equipment

—By Minor Wine Thomas, Ph.D. New York: Little & Ives, 1928. 128 pp. Price, \$1.50.

The aim of this book is to bring together and present the necessary criteria for judging plumbing equipment for use in the modern school. The necessary standards for the equipment of lavatories and toilets have been obtained from certain experimental evidence and from experience. In this manner the author has arrived at standards both as to material and design for the judgment of equipment to be used in the school building. A check list is provided so that each portion of the toilet room and lavatory may be judged on the basis of the standards adopted.

This volume should be of value to architects interested in the design of school buildings and to members of the school board. For the public health worker it should find good service in surveys of present school equipment.

LEONARD GREENBURG

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Yellow Fever—Two articles presenting an interesting resumé of yellow fever on the west coast of Africa, a note on epidemiologic research, and resolutions of a conference on control methods.

ANON. Yellow Fever in British West Africa. *Pub. Health Rep.*, 43: 31 (Aug. 3), 1928.

Preparalytic Poliomyelitis—A report of observations on 106 cases in which convalescent serum was used, which emphasizes the importance of early diagnosis. The authors conclude that convalescent serum gives a low mortality rate and low rate of paralysis, especially of the severer grades.

AYCOCK, W. L., and LUTHER, E. H. Preparalytic Poliomyelitis. *J. A. M. A.*, 91: 6 (Aug. 11), 1928.

Midwifery Supervision—The problem of training and supervising negro midwives in Georgia is discussed. The author asks if the employment of a physician in each county to supervise the midwives is the most effective method.

BOWDOIN, J. P. The Midwife Problem. *J. A. M. A.*, 91: 7 (Aug. 18), 1928.

Sickness Rates in Industry—A 10-year record of industrial sickness rates shows no appreciable decline. The outstanding causes are common colds and "indigestion."

BRUNDAGE, D. K. Trend of Disabling Sickness among Employees of a Public Utility. *Pub. Health Rep.*, 43: 30 (July 27), 1928.

British Cancer Campaign—This committee report reviews British cancer mortality statistics and outlines the national and municipal activities in research and control.

BUCHANAN, G. S. Public Action in Regard to Cancer. *Lancet*, 2: 4 (July 28), 1928.

Progress in Nutrition—Another of the author's summaries of progress in nutritional research of clinical observations. Invaluable to the field worker interested in health education.

BURNETT, F. L. Progress in Nutrition. *Northeast J. Med.*, July 26, 1928.

Poliomyelitis Prophylaxis—The use of convalescent serum as a prophylactic treatment against poliomyelitis in contacts is recommended—a 10 c.c. dose for children and 20 c.c. for adults.

FLEXNER, S., and STEWART, F. W. Specific Prevention and Treatment of Epidemic Poliomyelitis. *New England J. Med.*, 199: 5 (Aug. 2), 1928.

Epidemiology of Infections—A review of our present-day knowledge of the epidemiology of poliomyelitis, diphtheria, and scarlet fever by the director of the infectious disease department of the Rudolph Virchow Hospital in Berlin.

FRIEDMANN, ULRICH. Epidemiology of Children's Infectious Diseases. *Lancet*, 2: 5 (Aug. 4), 1928.

Diphtheria among Immunes—Among 11,608 Edinburgh children either found immune to diphtheria or immunized there occurred 58 cases of the disease with no deaths.

GRIERSON, A. M. M. Diphtheria Occurring in Sickened and Immunized Children. *Med. Off.*, 40: 3 (July 21), 1928.

Public Health Administration—What is wrong with health practice? Chiropractors, unsympathetic practicing physicians, untrained sanitarians, and industrial hygienists all come under

searching scrutiny. An excellent paper, all too brief.

HARRIS, L. I. Proposals for Next Steps in Preventive Medicine and Public Health. *J. A. M. A.*, 91: 8 (Aug. 25), 1928.

Vitamin B Deficiency—The symptoms of partial vitamin deficiency—loss of weight, spasticity of limbs, rigidity of neck, restlessness and fretfulness—occurring in infants whose mothers are fed a vitamin B deficient diet disappeared when fed yeast.

HOOBLE, B. R. Symptomatology of Vitamin B Deficiency in Infants. *J. A. M. A.*, 91: 5 (Aug. 4), 1928.

Goiter Prevention—A summary of a wide experience in goiter prevention by iodine administration, showing that it is effective and that it does not produce hyperthyroidism in old goiters. This is an effective answer to the calamity howlers who decried the general administration of iodine.

KIMBALL, O. P. The Efficiency and Safety of the Prevention of Goiter. *J. A. M. A.*, 91: 7 (Aug. 18), 1928.

Milk Supply Supervision—The Indiana health department program is outlined. It includes maintenance of laboratory service, general dairy inspection, uniformly effective municipal ordinances, elimination of tuberculosis and contagious abortion from herds, and education of the public to demand pasteurized milk.

KING, W. F. Control of Public Milk Supplies. *J. A. M. A.*, 91: 8 (Aug. 25), 1928.

Communicable Disease Control Measures—A plea for the search for nasal carriers of diphtheria, scarlet fever, measles, and chicken pox as a function of the local health department's epidemiologic service.

LEWIS, D. M. Insufficiencies in Methods of Control of Certain Respiratory Diseases. *Med. J. & Rec.*, 128: 3 (Aug. 1), 1928.

Measles Prophylaxis—Another report of successful prophylaxis against measles in a child-caring institution by means of Tunncliffe's anti-measles serum.

PETERMAN, M. G. Prevention of Measles. *Am. J. Dis. Child.*, 36: 1 (July), 1928.

Occupational Therapy—Occupations found suitable for tuberculous patients at Leysin clinics should be suggestive for health workers interested in problems of occupational therapy.

ROLLIER, A. The Work-Cure in Surgical Tuberculosis. *Brit. J. Tuberc.*, 22: 3 (July), 1928.

Measles Prophylaxis—A report of a series of experiences in which convalescent measles serum was found a safe and effective preventive when given in adequate dosage within the first three days after exposure.

SUTHERLAND, D. S., and ANDERSON, D. S. Serum Prophylaxis in Measles. *Lancet*, 2: 4 (July 28), 1928.

Relapse in Tuberculosis Convalescents—The importance of post-sanatorium care for tuberculosis convalescents is stressed in this paper. With proper aftercare 80 per cent of one group of convalescents were at work 7 years after discharge, whereas 52 per cent of a group inadequately cared for had relapses.

TAYLOR, H. L. Relapse in Pulmonary Tuberculosis. *Am. Rev. Tuberc.*, 18: 1 (July), 1928.

Community Nursing—A discussion of the problems of oversupply of private duty nurses and failure to make a complete utilization of public nursing service.

On page 1083 of the August *JOURNAL*, two references to the *Northeast J. Med.* should have read *New England J. Med.*

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Detroit, Mich.—Under the title, "Detroit's Healthiest Year," the 1927 report of the Health Department is published in the January bulletin. The report opens with a statement of aims and methods. The average death rate from 1923 through 1927 was 11.6, as compared with a rate of 14.4 for the period 1913 through 1917. This rate of 11.6 represents a saving of 16,940 lives over the number who would have died if the earlier rate of 14.4 had prevailed. More striking is the decrease in infant mortality from 115.4 for the period 1913-1917 to 80 for the years 1923-1927, a saving of 5,570 babies. A very pronounced drop in the death rates of what are usually the city's most important causes of death—pneumonia and heart disease—to rates of 98.8 and 135 per 100,000 population, respectively, is noteworthy.

There was a considerable increase in rabies, from 233 animals examined with 89 positive findings in 1926 (227 people given anti-rabic treatment) to 442 animals examined with 265 positive findings (520 persons treated) in 1927. A severe type of diphtheria continues, with 11 deaths per 100 reported cases.

Results of bacterial analyses of pasteurized milk tabulated by months show that 69.8 per cent of them were below 50,000 in 1927 as compared with 55.9 per cent in 1926. This city of 1,290,000 population has an annual consumption of milk of 51½ million gallons.

In 1925 the infant mortality rate for the city as a whole was 80.1, while the rate for babies who attended the prenatal clinics of the department was 69.5. In 1926 the general infant mortality rate was 85.1, that for the 2,019 babies born to mothers who attended the prenatal clinics being 55.4.

The report abounds in excellent sta-

tistical tables and charts, accompanied by descriptive text. A classified financial statement and a personnel chart add value to the report. It is written in semi-popular style, covering problems of interest to laymen as well as to public health workers.

Palo Alto, Calif.—Palo Alto's organization chart for 1927 shows that the health personnel for this city of 11,900 consisted of a health officer, a dairy and food inspector, 2 public health nurses, a sanitary inspector, a bacteriologist, and a clerk. The latter 2 also perform certain duties for other city departments. An expenditure of \$1.03 per capita is recorded. The flyleaf of the report bears an effective chart of Palo Alto Public Health Milestones, arranged on the order of the A. P. H. A. historical chart. The first health officer here was appointed in 1894 (on a full-time basis in 1910), and an assistant was added in 1914.

A death rate of 11.1 was recorded, 48.5 per cent of the 132 deaths occurring among persons over 70 years of age. An infant mortality rate of 21.9 is noteworthy, the rate in 1926 being 29.6. During the year, there was an increased incidence of poliomyelitis in the state, Palo Alto having 15 cases with no deaths. "In the control of communicable diseases a policy of always giving full publicity to the situation has been followed and has, it is felt, thoroughly justified itself."

Ten years ago, a public health nurse was first employed in this city. The plan of having the school and health department work combined and done by one set of nurses has been followed successfully since the beginning. In this arrangement the salaries and transportation of the nurses have been shared

jointly with the school board, while the supervision has been in the health department.

Colorado Springs, Colo.—Beautiful photographs of the surrounding country feature the Colorado Springs Health Department report for 1927. A psychiatric clinic was organized for work in the county, "the outgrowth of a demand which has been felt and recognized by citizens, social workers, teachers, and others interested in the health and education of children."

It is reported that during the past 15 years only 45 cases have acquired and developed tuberculosis in this city of 36,000. A review of the records of 30 cases which have died in the past 10 years shows that 14 of them were cases of tuberculous meningitis who died in infancy or childhood. These were in most instances children living with parents who were known to be tuberculous. The resident death rate from pulmonary tuberculosis for the past 10-year period is recorded as 4.4 per 100,000 population.

Improvement in the milk supply is indicated by bacteriological results. Average bacterial counts in 1925 were 144,200; in 1926, 51,700; and in 1927, 24,700. An ordinance has been framed corresponding closely with the Standard Ordinance of the U. S. Public Health Service.

Nova Scotia—The population of the province in 1927 numbered 523,837. Births are classified by counties, cities and towns, by years, the birth rate for the year ending September 30, 1927, being 21.2. A crude death rate of 11.9 and a standardized rate of 10.5 are recorded. An infant mortality rate of 90.8 is calculated, individual rates by counties varying from 43.7 to 141.7. Except for 1925 and 1926, the rate from tuberculosis has been steadily falling, and the Tuberculosis Commission is

credited with a comprehensive control program.

An unusually severe outbreak of infantile diarrhea occurred in the mining district around Glace Bay during the months of August and September; 65 per cent of the 60 deaths among infants were under 9 months of age. "The majority of these infants were or had been fed on cow's milk. . . . The use of raw milk in a place where there existed no means of protecting or preserving it, in an area where outdoor toilets are extensively used, and all the conditions present for the breeding of flies, prepares the way for a very rapid spread of communicable disease of any kind once it makes its appearance." Following this outbreak, recommendations for preventing recurrence, and a set of by-laws regulating the milk supply were submitted to the council of this district. In general, fewer communicable diseases than usual were reported in the province.

Pasadena, Calif.—This 1927 Health Department report contains a table of contents, a letter of transmittal, listing outstanding features of the year's work, photographs of the new city hall in which the department is housed, a health center, and a preschool conference, good statistical charts and tables, and interesting summaries of the divisions.

The milk ordinance was amended to provide, among other things, that all milk handlers be regularly physically examined. The first annual Tournament of Health Week, May 1-7, in conjunction with the Council of Social Agencies, was sponsored. Additional health conferences were established by the child hygiene division in coöperation with the Parent-Teacher Associations. "The women of the Pasadena Civic League who assisted the inspection division of the health department during the past year and served without pay, are to be commended for their interest and work." A campaign for immunization against

diphtheria among children under 12 years of age has been waged.

This city of 80,192 population reports a general death rate of 10.9, a tuberculosis mortality rate of 53 (per 100,000), a birth rate of 14.7, and an infant mortality rate of 53.

Quincy, Mass.—The activities of the Quincy Department of Health for the year 1927 appear in a 9-page mimeographed report modelled on the scoring system adopted by the American Public Health Association. In 1926, the Field Director of the American Public Health Association appraised the activities of this city of 65,275 people. At that time a score of 711 out of a possible score of 1,000 points was reached. During 1927, the city itself surveyed its activities and considerable improvement was noted as a result of the adoption of recommendations.

A death rate per 1,000 population of 8.6 and an infant mortality rate per 1,000 live births of 56.4 are reported. Total expenditure for health work during 1927 amounted to \$55,303.08; the per capita cost being 84½ cents.

Bradford, O.—The sanitary survey of Bradford, O., is the first of a series of similar surveys of the incorporated towns of Miami County, conducted under the auspices of the Miami County Board of Health. On May 3 and 4, 1928, every house was visited and the residents were interrogated with reference to the number in the family, age, sex, births and deaths and other data pertaining to water supply, milk supply, previous illness, etc. The premises were inspected with special reference to sanitary conditions of wells and toilets, the privy conditions presenting one of the largest sanitation problems of the town. A brief history of the town from its founding in 1865 is of interest, and is followed by the vital statistics report. In 1920 the town had a population of

1,503, in 1928 an estimated population of 1,050, the loss of 498 being accounted for by the removal of certain activities of the Pennsylvania Railroad from the town. During the present survey 335 homes were visited and data obtained from 231, totalling 895 persons. Of these, 453 were male and 442 female. A death rate of 14.4 and a birth rate of 22.6 per 1,000 population in 1927 are recorded. A large supply of Bradford's milk is pasteurized, and practically all milk used is controlled by the Board of Health's inspection. The per capita consumption is 0.48 pint daily.

Suggested improvements follow each separate sanitary problem discussed, and this 10-page mimeographed report concludes with a section summarizing all principal recommendations given by the surveyors.

A. I. C. P.—The 84th annual report of the A. I. C. P. reviews the association's activities for the fiscal year 1926-1927. A 2-page summary of the family welfare "services you made possible during 1926-1927" gives an enlightening survey of the type and volume of the work. The expenditures of the various bureaus and committees, with descriptions of the work of each of these sections, are listed, and total \$1,276,170. Detailed events of the A. I. C. P. since its organization in 1843 graphically describe the progress which has been made during the past 84 years. A page devoted to the "Officers and Managers" is followed by a chapter entitled "The Larger Task Ahead—with yesterday's problems solved come tomorrow's unmet needs."

The last half of the report, printed on paper having a dull finish in contrast with the glossy finish of the first half, is given over to committee memberships, bequests, legacies, funds and gifts. The report is bound in blue covers and is attractively arranged with chapter or section headings well selected to arouse the

interest of the lay reader. Interspersed throughout are many excellent photographs of individuals or groups helped by the association, together with a picture of one of the 4 attractive boys' camps conducted by the A. I. C. P., where boys spend "glorious weeks of life in the woods, plunging every day in lakes and rivers, learning to be 'reg'lar fellers' by the give and take process, growing both in desire and ability to choose between things worth while and their opposite."

Brookline, Mass.—The report of the Brookline Board of Health for the year ending December 31, 1927, opens with a financial statement of the activities of the board for the past 4 years, together with a recommended budget for 1928 of \$258,355, \$10,084 more than the amount appropriated in 1927.

In April, 1927, a health survey was made at the joint request of the Health Department and the Brookline Friendly Society. On the basis of the *Appraisal Form* of the American Public Health As-

sociation, a total of 848 points out of a possible 1,000 was obtained; tuberculosis control, prenatal work, preschool work, sanitary inspection and water supply receiving full score.

In 1923 an intensive campaign to secure the immunization of all children was started and has been continued each year since. During the 4 years previous to 1923 there were 209 cases with 9 deaths, as compared with only 43 cases and no deaths since that year. Of these 43 cases, there were none who had had the protective treatment.

A mortality rate of 11.06 per 1,000 inhabitants in 1927, in contrast to 11.39 in 1926, is noteworthy. A total of 615 babies were born during the year, 43 of which were to non-resident parents. Thirty-eight deaths of infants under 1 year (stillbirths excluded) occurred in this city of 45,021 people (estimated as of July 1, 1927). Brief but inclusive reports of the different bureaus of the department follow the health officer's report and conclude the report.

NEWS FROM THE FIELD

HEALTH NEWS FROM TENNESSEE

TENNESSEE now has 23 full-time health departments. One was recently organized in Knox County, with Dr. A. E. Richards as director. The department staff will consist of the director, two nurses, a sanitary inspector and a clerk. Another full-time health department has also been organized in Monroe County.

Dr. John Shell has been appointed full-time director of the Carter County Health Department at Elizabethton, Tenn. Dr. Shell recently completed the training course for health officers given by the Tennessee State Health Department and Vanderbilt Medical School.

OPTIMISTIC "NO DIPHTHERIA" REPORT FROM QUINCY

MORE than 3,700 boys and girls of Quincy, Mass., have been immunized against diphtheria at clinics conducted by the local health department since the inauguration of its toxin-antitoxin treatment in May, 1927. The appeal for the protection of their children against diphtheria was made directly to the parents. Of the 3,700 receiving treatment more than 3,000 have been of school age. Quincy reports that since 1923 there has been a consistent decrease in diphtheria morbidity rate and the first 8 months of 1928 show a decided decrease over previous years. The records of the health department also show that no child who has been successfully immunized has contracted diphtheria. Now Quincy is endeavoring to eliminate diphtheria among preschool children by the establishment of weekly diphtheria prevention clinics and by

seeking the coöperation of parents of preschool children.

VISION OF SCHOOL CHILDREN TESTED

OF 2,000 school children examined by a specialist in defects and diseases of the eye under direction of the U. S. Public Health Service, 45 per cent needed glasses for school work. The children examined were representative of the general school population. The Surgeon General calls attention to the necessity of making visual tests of school children at least twice a year to detect nearsightedness which may progress rapidly within a year. The report shows that the nearsighted eye can usually be detected by the Snellen chart test. Farsightedness can always be discovered by this test chart.

It was discovered that 60 per cent of the children may read normally on the vision test chart and 32 per cent of these are definitely farsighted and are constantly straining the eyes in near work.

NEW ENGLAND HEALTH INSTITUTE

AT the Sixth Annual New England Health Institute held in Burlington, Vt., in September the several aspects of public health were discussed. Emphasis in the program was placed on preventable diseases, sanitation and engineering, tuberculosis, child hygiene, public health nursing, the relation of social work to public health, mental hygiene, industrial hygiene, food, drugs and nutrition.

The institute was directed this year by Charles F. Dalton, M.D., secretary of the Vermont Department of Public Health, and it was sponsored jointly by

the State Health Departments of New England, the U. S. Public Health Service, several New England colleges and voluntary health agencies.

SEWAGE CONFERENCE AT CLEBURNE, TEX.

A SPECIAL sewage field conference was held at Cleburne, Tex., August 27, to discuss the recent developments of vacuum degasification at the Cleburne sewage disposal plant. This plant began its operations January 1, 1928, and the work accomplished seemed to merit further study according to the sanitarians who were influential in calling the August conference together. From reports of those in charge of operations of the plant it is claimed that this new process minimizes odors, increases the rate of sedimentation, and sludge digestion, eliminates foaming, and is helpful for the entire purification cycle.

Dr. J. C. Anderson, Texas State Health Officer, was chairman of the conference, and Dr. F. E. Giesecke, director of Engineering Research of Texas A. & M. College, was vice-chairman. Several valuable papers on the process were read, and briefer contributions made by engineers and sanitarians from several western and southwestern states.

NEW SECTION ON SANITARY ENGINEERING OF U. S. PUBLIC HEALTH SERVICE

A SECTION on sanitary engineering has been established in the Domestic Quarantine Division of the U. S. Public Health Service, to coordinate the engineering activities of the Domestic Quarantine Division and make practicable their detailed supervision by an experienced sanitary engineer. One of the pieces of work to be directed immediately will be the combination of the shellfish sanitation program with that of the interstate districts. Heretofore the office of shellfish sanitation has existed as a separate unit.

Field offices have been established in many of the interstate sanitary districts of the country.

CINCINNATI FINANCES A HEART PROGRAM

THE Community Chest of Cincinnati, O., has appropriated \$7,350 for the first year's work of the Cincinnati Heart Council recently established and the Amanda Bernheim Foundation has made an appropriation of \$5,000.

MISSOURI WATER CONFERENCE MEETS

THE Fourth Annual Meeting of the Missouri Conference on Water Purification will be held at Hannibal, Mo., November 15, 16, 17, 1928. The program will include topics on the following subjects: Water purification, deep and shallow well supplies and sewage treatment.

TEXAS SANITARIANS TO HOLD SHORT SCHOOL

THE Sixth Annual Texas Sanitarians' Short School will be held November 7-10, at San Antonio, Tex., with headquarters at Gunther Hotel and the City Health Department.

Dr. W. A. King, City Health Officer of San Antonio, president of the Texas Association of Sanitarians, is director of the school. Dr. J. C. Anderson, State Health Officer, is chairman of the program committee and he is being assisted by C. M. Adams, J. Bryan Miller, Mary Kennedy, Dr. W. A. Dunn, Dr. A. H. Flickwir and Dr. L. H. Martin.

This short school is one of the series arranged for intensive training of sanitarians and is sponsored by the Texas State Department of Health, the Texas Association of Sanitarians, the American Public Health Association and local health departments. The committee anticipates an attendance of 300.

PERSONALS

DR. GERTRUDE STURGES, formerly Assistant Director of the Cleveland Health and Hospital Survey, and for 3 years assistant executive secretary of the New York Associated Out Patient Clinics, has been appointed a member of the staff of the Committee on the Cost of Medical Care, Washington, D. C.

ALDEN MILLS, formerly Secretary of the Portland City Club, Portland, Ore., and Allon Peebles, instructor of economics at Columbia University, New York, N. Y., for the past 4 years, have recently accepted appointments to the staff of the Committee on the Cost of Medical Care, Washington, D. C.

DR. FRANK J. FULLER, Health Officer of Potsdam, N. Y., since 1915, died August 4.

THOMAS B. OSBORNE, PH.D., for forty-two years chief of protein research of the Connecticut Agricultural Experiment Station, New Haven, Conn., has retired from active directorship of the laboratory, and Hubert B. Vickery, Ph.D., is in charge. Dr. Osborne assumes the title of advisory biochemist.

DR. CHARLES H. NIELSON, president of the St. Louis City Medical Society, has been appointed Associate Dean of St. Louis University School of Medicine to succeed the late Dr. Don R. Joseph.

DR. RAPHAEL B. DUFEE, Bisbee, Ariz., was elected president of the Arizona Public Health Association.

DR. FRANK C. STORY has taken up his duties as health officer of Wayne County, Ga.

DR. FREDERICK E. JACKSON has been elected president of the Indianapolis, Ind., Board of Health.

FREDERICK L. HOFFMAN, LL.D., of the Prudential Life Insurance Company,

Newark, N. J., on his return from a transcontinental air journey, stopped in the Navajo country to assist the Bureau of Indian Affairs with the census of the Indians.

JANE C. ALLEN, for the last two years general director of the National Organization for Public Health Nursing, New York, N. Y., recently presented her resignation.

DR. ALBERT E. KYTE, Health Officer of the town of Montgomery, N. Y., died recently. Dr. Kyte had been health officer there since 1926.

W. C. BLASINGAME, who has held the position of director of the bureau of venereal diseases in the Alabama State Department of Health, has resigned to accept a position as director of the bureau of citizenship in the extension department of the University of Alabama, at Tuscaloosa.

DR. DOUGLAS L. CANNON has been appointed acting State Health Officer of Alabama, with full authority, until further notice. This vacancy was created through the death of Dr. S. W. Welch, who had been State Health Officer for many years.

GEORGE A. COOPER of the Monongahela West Penn Public Service Company, Fairmont, W. Va., has been appointed an Assistant Chief Business Specialist in the Division of Simplified Practice of the Bureau of Standards, U. S. Department of Commerce.

DR. EDWIN W. BATHURST has been appointed Health Officer of Edna, Calif.

DR. FRED J. WAMPLER has been appointed Professor of Preventive Medicine in the Medical College of Virginia, at Richmond, and Medical Director of the outpatient department. The September JOURNAL stated, in error, that these positions were in the University of Virginia.

Sanitation of Watersheds*

E. SHERMAN CHASE, FELLOW A. P. H. A.

Metcalf & Eddy, Engineers, Boston, Mass.

THE sanitation of watersheds tributary to public water supplies is a matter of growing importance in these days of extreme human motility resulting from the development of the automobile and good roads. Catchment areas, once remote, sparsely inhabited and infrequently visited, have become easily accessible to the hosts of pleasure seeking motorists. This state of affairs is of primary importance in the case of those water supplies subject to no purification other than that afforded by storage alone or by storage and chlorination.

It is essential in considering this matter of watershed sanitation to recognize that the problems involved vary with the different types of watershed. A convenient and logical classification is as follows:

1. Relatively large river watersheds with cities and towns thereon
2. Watersheds of the Great Lakes
3. Watersheds of moderate area with storage reservoirs or natural lakes, giving many months' storage for the natural runoff
4. Small or moderately large watersheds with little or no storage

A different classification, given in the first edition of the *Manual of Water Works Practice* of the American Water Works Association, takes into consideration the presence or absence of filtration. For comparing water supplies as delivered, it is manifestly necessary to give proper weight to the artificial methods of purification in use. It is not proper, however, to consider the use or non-use of such purification methods when a comparison of sources of supply is involved.

It is impossible to treat large watersheds upon which there are municipalities discharging sewage directly into the stream, or industrial establishments pouring wastes of various kinds therein, in the same manner as sparsely populated upland drainage areas. For the sanitary protection of water supplies derived from heavily polluted

* Read before the Public Health Engineering Section of the American Public Health Association, at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

streams, like the Hudson and Ohio Rivers, it is necessary to rely almost wholly upon water purification devices. Where supplies are taken from the Great Lakes, it is also difficult to accomplish much in the way of sanitary protection by watershed sanitation alone. In the case of the other two classes, watershed sanitation plays an important part in the maintenance of the purity of the supplies derived therefrom and this paper will deal with these two types of watersheds.

The most important hazard to water supplies is that resulting from indiscriminate discharge of sewage into the streams or other bodies of water from which water supplies are taken. The degree of danger will depend upon many factors: the population contributing sewage, the ratio of sewage to stream flow, the distance between point of sewage discharge and the water works intake, time of year, and the opportunities available for self-purification by sedimentation, sunlight and other natural processes.

On any populated watershed, besides the regular sources of pollution, there are sources from which pollution reaches the watercourses or reservoirs only intermittently, such as at times of melting snow or heavy rainfall. The classic epidemic at Plymouth, Pa., is an outstanding example of the infection of a public water supply by the excretions from a single typhoid case on a relatively sparsely populated watershed at the time of melting snow and freshet conditions.

Whenever there is a single human being upon a watershed, there is also a chance for dangerous pollution. With one person the chance is very remote for any serious consequences to occur but with every additional person upon that watershed there occurs an increased possibility of pollution and infection. It is impossible to fix a limit of permissible population; the fewer, the better.

Highways and railroads parallel to and crossing over water supply streams and reservoirs are well recognized sanitary hazards due to the fact that they render the streams and lakes accessible to many more people than would otherwise be the case. Regulations requiring locking of toilet compartments in passenger cars on the railroads only partly reduces the danger of contamination.

Lumbering operations and labor camps are difficult to control effectively, due to their semi-permanent nature, which often results in sanitary conveniences being crudely and improperly taken care of.

Among the recreational uses of watersheds in which occur some sanitary hazard are hunting and fishing. Fishing brings the transient visitor directly upon the watercourses or upon the reservoirs and lakes. The fisherman is never far from the water. The hunter will cross and re-cross tributary streams many times in the course of a single day,

and in duck-shooting the hunter will be directly upon the pond or reservoir.

Picnic parties are undesirable and in some ways are potentially more dangerous than hunting or fishing due to the fact that picnics are usually composed of a considerable number of people. Without proper sanitary conveniences, pollution of the ground and eventually of the watercourses is very likely to occur.

In the matter of boating upon and bathing in water supply reservoirs, there should be no difference of opinion. There seems to be, however, a tendency in recent years to overlook the hazard resulting from these practices, particularly where purification is resorted to. The recent Report of the Committee on Water Supplies of this Association¹ distinctly leans toward allowing such recreational uses of water supply streams and reservoirs:

Swimming in streams appears now to be the most common sanitary problem and the hardest to tackle, being so generally indulged in and so slight in its sewage pollution. We suspect the real objection to it is principally a mental and esthetic one, which, however, cannot be entirely overlooked.

This much is certain, that water consumers cannot look to the recreationist or other users to guarantee the safety of the supply. The consumers themselves can easily make the supply safe and entirely potable. It is preposterous to deny mountain recreation to the multitudes that the consumers may be spared the inconvenience of water treatment. The health department will succeed well if it holds recreational abuse in bounds and preserves such a degree of cleanliness as the pleasurable uses themselves dictate.

The committee apparently stands for cure rather than prevention, a policy directly opposed to the general policy of this Association. The intimation that swimming in streams is a matter of small sanitary significance from the standpoint of pollution is directly in contradiction of the facts as shown by the increase in bacterial content of swimming pool waters or in the waters at bathing beaches.

Analyses by the Massachusetts Department of Public Health have shown more bacterial contamination in the sea water among the bathers at Revere Beach than in Boston harbor waters 1,400 feet from the outlet of the South Metropolitan Sewer District.² The 1923-25 report of the Division of Water Supply Control of Chicago gives data showing the high bacterial content of the waters at Chicago's bathing places, including beaches, and outdoor and indoor swimming pools.³ Langdon Pearse, in the JOURNAL for June, 1927,⁴ referring to the pollution at bathing beaches, states: "In Chicago the pollution from the large number of bathers, however, is more important than the lake pollution from other sources."

The evidence is unmistakable that bathing in sources of water

supply is a real and not an imaginary sanitary hazard. This depends in large measure upon bathers' proximity to the water works intake—the nearer the intake, the greater the danger. The hazard is greater in small than in large reservoirs, and the more bathers, the greater the risk. It should be realized, moreover, that in relatively large reservoirs contamination and even infection can be carried several miles under favorable conditions of wind and currents. This was shown by the experience of Auburn, N. Y., in 1907, where infection by sewage of the feeder of Owasco Lake, its source of water supply, was carried to the water works intake a distance of 14 miles from point of infection,⁵ of which distance 10 miles were across the lake.

Actual evidence of contamination by fishermen, hunters and picnickers is difficult to obtain and evidence of infection, even more difficult. At Peabody, Mass., in 1913 there occurred an outbreak of at least 1,500 cases of intestinal disorder which was attributed after careful investigation by the State Department of Public Health to an infection by fishermen of one of the ponds used as sources of water supply.⁶

In connection with the recreational use of watercourses and reservoirs it should be recognized that, if such use is permitted, real estate developments will follow, particularly if the sources of supply are near centers of population. Once the barriers are removed there will be no stopping the increasing sources and acts of contamination. Those interested in the results of the removal of restrictions against recreational use of a water supply pond should refer to an article by X. H. Goodnough and the discussion thereof by Albert L. Sawyer.⁷

Other activities contributing to contamination are ice cutting, lumbering, and the establishment of labor camps, to which have been attributed outbreaks of water-borne typhoid fever. Instances of such outbreaks have been reported at Hillsdale, Mich.,⁸ Raybrook, N. Y.,⁹ and Ithaca, N. Y.¹⁰ While the actual ice cutting operations in winter are often conducted under sanitary supervision, there is usually no oversight of the men engaged in loading and hauling ice from the ice houses during the summer.

The first course of action for the sanitary protection of watersheds which naturally occurs to water works authorities is the purchase of watershed lands, particularly marginal areas around reservoirs and ponds and along watercourses. In the case of the North Jersey Water Supply Commission a marginal strip of land around the entire shore of the new Wanaque reservoir will be owned by the district. For the Honeoye Lake water supply development of the City of Rochester, N. Y., the consulting engineers, Hazen, Eddy and Fisher, have recom-

mended the purchase of large areas of land totally enclosing the proposed reservoir. Many other instances of heavy purchases of watershed lands could be cited.

The ownership of watershed lands allows thorough sanitary control of such lands and the prevention of much pollution which would otherwise occur. Large water supply developments permit the employment of sanitary police, but smaller developments must depend upon regular and reasonably frequent inspections by water works employes for preventing trespassing and acts prejudicial to the quality of the water supply. On those areas outside of water works lands, sanitary inspectors can be of much service in the matter of securing, largely through coöperative efforts, the maintenance of proper conditions on inhabited properties. Furthermore, arrangements with physicians practicing in the district for the prompt reporting of typhoid fever and other water-borne diseases will permit the water department to insist upon the necessary precautions with respect to the disposal of the infectious excretal discharges of the patients. It is obvious that sanitary patrol cannot prevent all sources or acts of contamination, but it can abate and prevent many such.

For sanitary policing to operate upon rational lines it is of distinct value for watersheds to be protected by rules and regulations enacted by the state department of health. In Massachusetts and New York the State Health Departments have been given authority by their respective legislatures to make rules and regulations for the protection from contamination of all sources of public water supplies within the borders of the state.¹¹ In both states this authority has been acted upon, and many of the water supplies are protected.

In general these regulations proscribe certain acts of contamination and regulate the distances at which sources of possible contamination may be located with respect to reservoirs, ponds and watercourses tributary to public water supplies. These regulations are not generally applicable to all supplies within the state but are enacted separately for individual supplies, and usually only when the local authorities express a desire for such rules and a willingness to enforce them.

In Massachusetts the rules and regulations are practically alike for all supplies while in New York the rules vary with the individual supplies according to local conditions. The latter policy is distinctly more rational. For a very complete discussion of the laws relating to the control of water supplies in New York State reference should be made to a paper by C. A. Holmquist.¹²

The following brief abstract of rules and regulations for Massachusetts watersheds indicates their nature:

No place for the temporary deposit of human excrement is allowed within 50 feet of the high water mark of reservoirs, ponds or watercourses and no place for the permanent deposit of such matter is allowed within 250 feet of such waters. Furthermore, no deposition of human excrement upon the ground is permitted at any point where it may be washed into the sources of the supply. The discharge of sink wastes or other polluted water directly into reservoirs, ponds or streams is forbidden as is such discharge into the ground within 50 feet or upon the ground within 250 feet thereof. The placing of garbage, manure or putrescible matter into sources of supply is forbidden as is the placing of such matter upon the ground within 200 feet. An exception is made, however, in the matter of the ordinary use of manure in agriculture as regards placing of such material upon the ground. Stables and other animal enclosures are forbidden within 50 feet of streams and reservoirs and are not allowed within 200 feet of these unless provided with suitable means of storing manure. Burials are forbidden within 50 feet of sources of supply. Provision is made in the rules for the approval by the state health department of new cemeteries upon the watershed. The discharge of manufacturing wastes into sources of water supply is forbidden. Sewer systems and sewage treatment plants must be approved by the health department and no private sewer is allowed with an outlet within 250 feet of reservoir, pond or stream. Hospitals for persons with infectious diseases cannot be located on watersheds without approval of the health department, and hospitals must make proper provision for the disposal of sewage. The same is true as regards tanneries, slaughter houses, and rendering plants. Bathing in ponds and reservoirs is prohibited and fishing and boating thereon is permitted only by special regulation of the health department. Ice cutting also is allowed only by special permit. Reports of infectious disease occurring upon watersheds must be kept accessible to the water works authorities.

The rules and regulations of New York State cover much the same ground. In most New York rules the limiting distances are greater with respect to reservoirs and primary sources of supply than in the case of watercourses tributary thereto. Furthermore, as previously stated, each set of New York rules is prepared with special reference to the local conditions affecting the particular supply for which the rules are enacted. Consequently, limiting distances vary for different supplies. Another difference lies in the fact that in Massachusetts natural ponds and lakes over 10 acres in area constitute "great ponds" and are the property of the Commonwealth, which has authority to exercise complete control of such waters. In the case of New York, riparian owners cannot be deprived of their rights in bodies of water without compensation therefor.

To determine the policy of other states in the matter of rules and regulations similar to those of Massachusetts and New York inquiries were sent to the chief engineers of health departments of all the states. As a result of these inquiries replies have been received from all but 1 of the 48 states. These replies are briefly summarized in Table I.

From this it will be seen that but 4 states prepare detailed and specific rules and regulations for the sanitary protection of water-

TABLE I

SUMMARY OF STATE REGULATIONS RELATING TO WATERSHED SANITATION IN THE UNITED STATES

Specific State Regulations	General State Regulations	Local Regulations by Muni- cipalities	State Regulations Being Revised	No Regulations	No Replies
Massachusetts	Arkansas	Colorado	Missouri	Alabama	South Dakota
New York	Connecticut	Louisiana	Tennessee	Arizona	
North Carolina *	Iowa	Ohio		California	
Vermont	Maine			Delaware	
Mississippi †	Maryland			Florida	
North Dakota ‡	Montana			Georgia	
	Nebraska			Idaho	
	New Hampshire			Illinois	
	New Jersey			Indiana	
	New Mexico			Kansas	
	Oklahoma			Kentucky	
	Oregon			Michigan	
	Pennsylvania			Minnesota	
	Rhode Island			Nevada	
	Utah			South Carolina	
	Virginia			Texas	
	Washington			West Virginia	
				Wisconsin	
				Wyoming	

* Rules applying to watersheds at four different sizes: (1) less than 20 sq. mi., (2) 20-50 sq. mi., (3) 50-100 sq. mi., (4) over 100 sq. mi.

† State Board of Health has assumed authority to make specific rules and regulations.

‡ State Dept. of Health has authority to make rules and regulations but has not exercised that authority.

sheds; namely, Massachusetts, New York, North Carolina and Vermont, although Mississippi and North Dakota have authority to do so but apparently have not availed themselves of this authority. Seventeen states control watershed sanitation by more or less general legislation; in 3 states municipalities have a certain amount of authority in the matter, while in 19 states there appear to be no regulations. In 2 states regulations are being revised. Of all the states, New York appears to follow the most logical procedure in the matter of watershed sanitation. Massachusetts is a close second and has an advantage in the fact that "great ponds" belong to the state.

It cannot be claimed that the mere enactment of rules and regulations constitutes an adequate sanitary safeguard. Such rules must be enforced and the enforcement rests in the main with the local authorities. Enforcement is not easy nor is it perfect, but there is no question as to the beneficial effects resulting therefrom.

In some quarters the view is held that watershed sanitation is comparatively unimportant as a means of protecting the purity of water supplies, and that the chief reliance should be placed upon water purification plants. Such a view is not wholly justified by facts. Table II gives the typhoid death rates of cities geographically.

TABLE 11

TYPHOID DEATH RATE IN CITIES OF THE UNITED STATES IN 1927 BY GEOGRAPHICAL LOCATION

State Group	Population	Typhoid Death Rate per 100,000
New England	2,540,209	1.26
Middle Atlantic	11,789,633	1.41
South Atlantic	2,244,300	3.39
E. North Central	8,319,500	1.31
E. South Central	854,300	10.07
W. North Central	2,520,400	1.86
W. South Central	1,698,946	6.71
Mountain and Pacific	3,508,435	1.74

From *I. A. M. A.*, May 19, 1928

From this it will be seen that the lowest death rate from typhoid last year occurred in the New England states where for many years the general policy in the matter of water supply sanitation has been to rely upon storage and clean catchment areas. This fact does not warrant the conclusion that New England cities should rest on their laurels, but it does show that New England methods of water supply protection, irrespective of opportunities for improvement therein, have been as successful, measured by the typhoid death rates, as those of other states.

Policies applicable to New England and to other states with similar opportunities for securing upland sources of supply cannot be adopted in all states. On the other hand, it is not proper to advocate the general adoption of policies relating to watershed sanitation which are contrary to those followed for years in the East with such good results.

The previous statements should not be construed as belittling the value of water purification methods. In general, most surface water supplies should either be chlorinated or chlorinated and filtered. But there are four lines of defense against impure water, namely, watershed sanitation, long storage, chlorination, and filtration. When possible, all four lines of defense should be utilized to the fullest extent practicable.

What We Are Learning about Accidents from Vital Statistics Records*

EARLE G. BROWN, M. D.

Secretary, State Board of Health, Topeka, Kan.

THE primary duty of all health departments is prevention—but not alone the prevention of the communicable diseases. Health departments are interested in all conditions which “make growth more nearly perfect, decay less rapid, life more vigorous, and death more remote.” Likewise, the individual is interested in the same problems.

For material on which to base the present discussion, data are used from the records of the Division of Vital Statistics of the Kansas State Board of Health. I am quite certain these statistics are comparable with those of any of the states in the U. S. Registration Area.

In the State of Kansas in 1927, only four diseases, and these all of a chronic type, caused more deaths than accidents. See Table I.

TABLE I
FIVE PRINCIPAL CAUSES OF DEATH IN KANSAS, 1927

	Number of Deaths	Death Rate per 100,000
Organic heart disease.....	2,612	142.3
Cancer, all forms.....	1,839	100.0
Cerebral hemorrhage.....	1,832	99.6
Chronic nephritis.....	1,534	83.4
Accidental deaths.....	1,345	73.1

Deaths from all causes in Kansas for the years 1914–1927, inclusive, total 273,801. Deaths from accidental causes for the same period total 15,682, or 5.7 per cent of the total. The percentage of accidental deaths by years varies from 4.2 per cent in 1918, the minimum, to 7.2 per cent in 1927, the maximum.

The only method of determining true health conditions is by a study of the death rates of a community. Perhaps it may be said, and correctly, that accidental deaths do not indicate health conditions; however, because they comprise approximately 6 per cent of total deaths, they have a very appreciable effect on the death rate of every community. In Kansas, the accident death rate per 1,000 population in the past 14 years has ranged from 0.51 in 1914, the minimum, to 0.73 in 1927, the maximum.

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

The success of accident prevention may in a way be measured by a comparison of automobile accident death rates with death rates of two of the principal preventable diseases which have been the object of consistent attack by the State Health Department in coöperation with city and county health departments. The comparison is made during the period 1914 to 1927, the former being the first year statistics are available for automobile accident deaths.

TABLE II

DEATHS AND RATES IN KANSAS PER 100,000 POPULATION FROM TYPHOID FEVER, DIPHTHERIA AND AUTOMOBILE ACCIDENTS

	Typhoid Fever		Diphtheria		Automobile Accidents	
	Deaths	Rate	Deaths	Rate	Deaths	Rate
1914	338	20.2	170	9.7	36	2.1
1915	196	11.7	245	13.7	45	2.6
1916	263	15.3	195	11.1	100	5.8
1917	332	19.1	136	8.6	112	6.4
1918	289	16.7	131	6.8	134	7.7
1919	135	7.6	191	10.7	116	6.5
1920	138	7.8	262	13.9	164	9.1
1921	155	8.6	382	20.9	154	8.6
1922	107	5.9	288	16.6	171	9.5
1923	111	6.1	151	8.7	213	11.7
1924	73	4.0	88	5.0	149	8.1
1925	101	5.6	71	3.5	235	12.9
1926	83	4.5	49	2.7	237	13.0
1927	66	3.5	75	4.0	253	13.7

Table II shows that death rates for typhoid fever and diphtheria have, with variations, decreased from 20.2 and 9.7 per 100,000 population to 3.5 and 4.0, respectively. Automobile accident death rates have, however, shown a steady increase from 2.1 in 1914 to 13.7 in 1927, with the exception of the years 1919, 1921 and 1924.

For comparison as to seasonal occurrence, studies were made by month, for the period 1923-1927, of three of the five principal types of accidental deaths.

Accidental drownings show a greater seasonal variation than any other one type of accident, as 76.1 per cent of these deaths occurred during the months of May, June, July and August.

Twenty-seven and one tenth per cent of the deaths from accidental falls occurred during the months of December and January. A study was not made, however, as to the month of occurrence of the injury. Obviously, the number of injuries of this type would be quite high during the winter months, especially when ice and snow were present on the ground.

Eleven and three-tenths per cent of the deaths from automobile accidents occurred during the month of August, when the days are warm and more automobiles are in use. It is also the season when great numbers of tourists are vacationing in their automobiles.

In our study of accident statistics, especial attention is directed to five principal types of accidents, which in the past 14 years have caused 8,922 deaths, or 36.8 per cent of the total, from accidents. These accidental deaths are shown in Table III.

TABLE III
FIVE PRINCIPAL TYPES OF ACCIDENTAL DEATHS

Accidental falls.....	2,542
Automobile accidents.....	2,118
Railroad accidents.....	1,879
Accidental drownings.....	1,214
Accidental burns.....	1,169

Twenty-five hundred and forty-two deaths, or 16.2 per cent of accidental deaths, resulted from accidental falls. We find in this type of fatal accident that approximately 58 per cent occur in the age group of 70 to 89 years, in that period of life when a slight misstep, tripping over a rug, or a fall from a bed or chair, may result in a serious injury and oftentimes the breaking of one or more bones. Frequently, due to the shock, death results in the course of a few hours or a few days. In many instances, death does not occur immediately and, due to old age and a lack of the necessary mineral elements for the growth or replacement of bone, the break does not heal. The result is that the individual becomes an invalid and remains practically helpless the remainder of his life.

In the 14-year period, 1,214 accidental drownings were recorded. Two-thirds of these drownings occurred in the age group under 20. In 1927 deaths from drowning showed a marked increase over previous years, due to flood conditions which occurred in the state the latter part of the summer. Accidental drowning of young children in stock watering tanks shows an increase. In 1926, 9 such drownings were recorded, but this number jumped to 24 for the year 1927.

The second greatest cause of accidental deaths is the automobile. A compilation of statistics made by the National Automobile Chamber of Commerce shows that more people have been killed by automobiles in the past 8 years than all deaths of American soldiers in the World War. From January 1, 1919, to December 31, 1926, automobiles killed 137,017. Total deaths of the American armed forces during the war were 120,050. Those injured in automobile accidents since the armistice number 3,500,000. Twenty-six per cent of the killed and injured were children under 15 years of age.

From 1914 to 1927, 2,118 deaths have occurred in the state as the result of automobile accidents, 253 of these deaths occurring during the year 1927. There occurred, during the 12-months period, prob-

ably 100,000 automobile accidents. Accidents always result in some damage to the automobile, and frequently death to the driver or occupants, and oftentimes serious injury. According to the National Safety Council, approximately 35 persons are injured for each death resulting from automobile accidents, and on that basis 8,855 would have been injured in Kansas during the past year. Considering automobile accidents from an economic standpoint, we find the loss for 1927, as follows:

8,855 injured at \$175.....	\$1,549,625
Damage to automobiles, 100,000 at \$50.....	5,000,000
253 deaths at \$4,000 *.....	1,012,000
Total.....	<u>\$7,561,625</u>

* In Kansas, \$4,000 is the sum allowed by the Workman's Compensation Act.

It would only seem logical that with an increase in the number of automobiles there would be an increase in the number of deaths. There has been a steady increase in the death rate per 100,000 population, but a decrease per 100,000 automobiles.

Undoubtedly, the general opinion prevails that the majority of deaths result from the collision of automobiles. Such is not true in Kansas. On the basis of reported deaths for 1927, 80, or 31.6 per cent, were pedestrians. By pedestrians are classified generally those who were killed in the street or public highway, and were not occupants of automobiles or other vehicles. Many of the 80 killed were children playing in or crossing the street. Sixty-four deaths, or 25.3 per cent, occurred as the result of an automobile skidding or overturning, many of them perhaps the result of speeding. Fifty-one deaths, or 20.1 per cent, were the result of the collision of automobiles with other motor cars, motor driven trucks or lighter vehicles.

The death rate for automobile accidents has been steadily increasing, there being only 3 years when deaths in Kansas did not show an increase over previous years. As previously stated, these decreases occurred in the years 1919, 1921 and 1924. I am unable to explain the decreases in the years 1919 and 1921, but that in the year 1924 is due to a change in statisticians in the Division of Vital Statistics, and the fact that some accidental deaths were not queried as to their cause.

During the year 1927, 181 deaths, or 71.5 per cent of the total of 253 deaths due to automobile accidents, were recorded as occurring in rural sections of the state.

Deaths resulting from railroad accidents have varied from 101 in 1919 to 151 in each of the years 1916 and 1917. It is rather a

coincidence that in 1914 there were 133 deaths and in 1927, 135 deaths. In 7 of the 14 years from 1914 to 1927, deaths ranged between 132 and 137.

Five and six-tenths per cent of the accidents in the 5-year period 1923-1927 occurred in the month of April, and the highest, 11 per cent, during the month of September. In the remaining 10 months, the percentage varied from 6.8 to 9.1.

Fifty-six of the 156 deaths were reported as the result of the collision of an automobile or motor driven truck with a railroad train at a grade crossing. This number represents 41.1 per cent of the total deaths from railroad accidents. Forty-one, or 73.2 per cent of these deaths, occurred as the result of accidents in rural sections of the state, or in cities and villages of less than 10,000 population. The 56 deaths were caused by 40 accidents—32 accidents resulting in single deaths; 5, each resulting in 2 deaths; 2, each resulting in 3 deaths, and 1 grade crossing accident resulting in 4 deaths.

In 1926, there were 27 grade crossing accidents, causing 41 deaths—17 causing 1 death; 7, each causing 2 deaths; 2, each causing 3 deaths; and 1 resulting in 4 deaths.

In 1927, there were 26 deaths of railroad employes resulting from railroad accidents and representing a total of 19.1 per cent from this cause.

Accidental burns, excepting conflagrations, caused 1,169 deaths. Including conflagrations, the total is 1,461. Thirty-eight per cent of these deaths in 1927 were under 20 years of age, and 39 per cent were over 50. The most common causes of accidental burns were given as starting a fire with kerosene, children playing with matches, clothes catching fire from open gas stoves or grates, and trash and bonfires.

There are a few additional types of accidental deaths that we shall discuss briefly:

Accidental injuries by machines have caused 414 deaths, and injuries by vehicles other than automobiles—trucks or motorcycles—have caused 357 of these. Many of these deaths were the result of runaway teams. It would seem in this day and age of the automobile and tractor that we should have very few of these accidental deaths. Yet, rarely a month passes that the division does not receive one or more certificates reporting this type of accidental death. The majority of these naturally occur in the rural sections of the state.

Accidents of an industrial nature are reportable to the Labor Department of the state, but other than these, the state law does not require reporting. Such data as have been given were secured through queries made of the physicians who have signed the death certificates.

It is only through the willingness of Kansas physicians to coöperate with the department that we have been able to secure the information which we consider so vital to a proper study of accidental deaths.

In the program for good roads in Kansas, the State Highway Engineer has recently advised us that more than 1,000 grade crossings have been eliminated in the past 10 years, the majority of them in the past 3 years.

SUMMARY

1. Accidental deaths cause approximately 6 per cent of total deaths.
2. Accidental deaths have an appreciable effect on the death rate of every community.
3. Five principal types of accidents cause more than 50 per cent of all deaths—the very great majority of these could be prevented if proper precautions were exercised.
4. Deaths from railroad accidents, falls, drownings and burns do not show much variation from year to year.
5. Automobile accidents and resulting deaths are decidedly on the increase.

Institute for the Health of School Children

A DECREE of the Minister of Public Instruction of Chile, dated March 23, 1928, provides for the establishment of an Institute for the Health of School Children, the purpose of which will be to guide the physical and mental development of children during their school life. The institute will consist of two divisions: division of education and division of school hygiene.

The division of education will provide courses in school hygiene for teachers and for the general public and courses to train nurses and home visitors.

The division of school hygiene will be in charge of the medical inspection of school children throughout the country. It will also study matters relating to the physical and mental development of school children and give information to the ministry of public instruction on these matters. Records will be kept of the physical and mental condition of the children throughout their school career.

Free dental and medical treatment will be provided for children whose parents are unable to pay. Laboratories, clinics, and other facilities for carrying out the work of the institute will be maintained by the public authorities.—*Diario Oficial de la Republica de Chile*, Santiago, Apr. 27, 1928, p. 2175.

Hearing Survey Among a Group of Pupils of Syracuse Schools

FRANK A. LAURER, M. D.

Syracuse, N. Y.

THE physical examination of school children presents many problems, not the least of which is the determination of the amount of deafness of the hard-of-hearing child.

The "watch tick" method, upon which many rely, is subject to great variation, depending on the make of watch, amount of noise in the room, understanding of the child as to what is expected of him and his response to the test, and the personal equation of the examiner. The same faults are true also of the "whispered speech" method of examination. Coupled with the above is the necessity of testing each child individually.

Recent surveys of the condition of hearing of school children in the United States seem to indicate that more than 3 million have hearing defects.

The published reports^{1,2,3,4} indicated that the Audiometer recently developed by the Western Electric Company could be depended upon to overcome the objection of the previous methods of examination, even to being able to test at one sitting with a minimum of time and a high degree of accuracy all the children in the usual schoolroom.

It was decided to conduct a survey to determine the amount of deafness in the schools of Syracuse. Eight schools were chosen to give a cross-section of the city. The work began October 15, 1926, and extended to May 31, 1927.

In order to determine the best method of carrying on the work in the future, the survey was made a special study independent of the work of the regular school examinations. The examiner was a physician specializing in ear work. He was assisted by the nurse and a clerk on a part-time basis.

Briefly, the Audiometer may be described as a phonograph from which the voice is transmitted through a magnetic telephone device, then through ear phones to the pupils. The records used resemble those of the ordinary phonograph, numbers only being transmitted in varying degrees of intensity. The range of the voice transmitting the numbers varies from a loud conversational tone to that of a barely audible whisper. One of the records transmits numbers of three

digits, as "526." This one was used in the 6th, 7th and 8th grades. The other record transmits numbers of two digits and was used in the 3d, 4th and 5th grades.

The Audiometer determines ability to hear the normal speaking voice, but does not include the upper limits of hearing. If a pupil, therefore, does not hear the voice of the Audiometer, it does not mean that he is totally deaf but that, as far as ordinary conversation is concerned, his hearing is impaired.

Standard record sheets and rating charts furnished by the Western Electric Company were used in the study. The record sheets used by the pupils for recording what they hear are graded in sensation units lost, ranging from —3 to 30, i.e., —3, 0, 3, 6, 9, 12, and so on up to 30. The —3 represents the highest rate of hearing and 30 the poorest. A child with a hearing loss of 27 or 30 units can hear very little of the normal speaking voice.

In rating the papers the standard advised by the Western Electric Company was used, i.e., that all pupils who could not hear 9 sensation units had impaired hearing. All those who failed on the first test were given a second test. All who failed the retest were given an ear, nose and throat examination to determine the probable cause of loss of hearing.

Schools in which the tests were to be made were selected with the idea of obtaining pupils of varied nationalities and living under different economic conditions. The quietest room available was selected for the tests. In four schools the stage of the auditorium was used; in two the cafeteria; and in the remainder a large classroom.

At the beginning of the survey but one tray of 8 ear phones was available. Later 12 ear phones were used, and about the middle of January, 1927, four additional trays containing 8 ear phones each were used. This made it possible to test 40 pupils (the capacity of the instrument) at one time.

The time used to test 40 pupils varied with the grades. The lower grades required more time than the upper. The minimum time was 10 minutes and the maximum, 45.

Tests were made in eight schools—three public, four parochial and one high school. The high school pupils were tested with the idea of comparing the results with those obtained in the grade schools.

A total of 4,790 pupils were tested—4,419 grade school and 371 high school pupils. Of this number 1,466 grade school and 84 high school pupils were retested. In all 6,711 tests were given with the Audiometer. Four charts were kept for each school, in each case recording the sex and grade:

Chart No. 1. Number tested, retested, number with impaired hearing

Chart No. 2. Number with impaired hearing by degrees

Chart No. 3. Presence or absence of tonsils and adenoids among those with normal and impaired hearing

Chart No. 4. Results of ear, nose and throat examination and recommendations

In this report we consider only the pupils tested in the grade schools, a total of 4,419. Of the 4,419 pupils tested, 502 or 11.3 per cent were found to have impaired hearing. The percentage of impaired hearing found among the boys was 10.6 per cent and among the girls 12 per cent.

The lowest percentage of impaired hearing at all ages, 1.9 per cent, was found at St. John's School where the pupils are mostly Americans and the economic conditions are excellent. The highest percentage of impaired hearing, 17.6 per cent, was found at Franklin School where the pupils are mostly of Italian parentage, and economic conditions are poor.

TABLE I
IMPAIRMENT AND ECONOMIC CONDITION

School	Nationality	Economic Conditions	Registration of Grades Tested	Number Tested	Number with Impaired Hearing	Percentage with Impaired Hearing
Assumption	German American	Fair	411	381	32	8.4
Delaware	American	Good	863	854	76	8.9
Franklin	Italian	Poor	1,125	1,116	197	17.6
Holy Trinity	German American	Good	125	125	5	4.0
Sacred Heart	Polish	Poor	1,071	1,009	118	11.7
St. John's	American	Excellent	316	308	6	1.9
Seymour	American (Mixed)	Poor	650	626	68	10.8
			4,561	4,419	502	11.3

TABLE II
DEGREES OF HEARING LOSS

School	Number Tested	Number with Impaired Hearing	Degree of Loss							
			9	12	15	18	21	24	27	30
Assumption	381	32	22	5	0	2	0	1	0	2
Delaware	854	76	46	13	7	3	0	2	3	2
Franklin	1,116	197	108	61	15	2	3	1	3	4
Holy Trinity	125	5	2	1	0	0	0	1	1	0
Sacred Heart	1,009	118	80	30	6	1	1	0	0	0
St. John's	308	6	2	2	1	1	0	0	0	0
Seymour	626	68	38	11	6	4	4	0	0	5
	4,419	502	298	123	35	13	8	5	7	13
			421		56			25		

421—Borderline of impaired hearing
56—Moderate degree of hearing loss
25—Severe hearing loss

The hearing loss among the 502 pupils found to have impaired hearing seems to be confined to a mild degree of hearing loss, as 421, or 83.8 per cent, had a sensation unit loss of 9 to 12. These may be considered as on the borderline of impaired hearing. Fifty-six, or 11 per cent, had a moderate degree of hearing loss; 25, or 5 per cent, had a severe hearing loss.

According to the 4,419 questionnaires filled in by the pupils given the hearing test, 1,094, or 24.7 per cent, claimed their tonsils and adenoids had been removed; however, upon examination this information proved unreliable. Of the 502 pupils with impaired hearing it was found that 410, or 81.7 per cent, still had tonsils and adenoids.

TABLE III

PUPILS WITH IMPAIRED HEARING WITH TONSILS AND ADENOIDS PRESENT

Grade	Average Age	Number with Impaired Hearing	Number with Tonsils and Adenoids Present	Percentage
3d	8	106	78	73.6
4th	10	130	116	89.2
5th	11	113	94	83.2
6th	12	74	63	85.2
7th	13	42	33	78.6
8th	14	27	20	74.0
Ungraded ¹	12 to 16	10	6	60.0
		502	410	81.7

1. Ungraded class located at Seymour School
Not considered for comparison purposes

We regret that, owing to the fact that work was done in Franklin School between semesters, we were unable to examine for ear, nose and throat defects the 197 pupils found there with impaired hearing, and 3 Assumption School pupils who were absent when the special examination was made.*

The cause of impaired hearing was classified into three general groups as follows: External ear, 54, 17.8 per cent (caused by wax or cerumen in the external canal); middle ear, 227, 75.1 per cent (194 or 85.4 per cent due to chronic catarrhal condition, 33 or 14.6 per cent due to chronic purulent discharge); inner ear, 11, 3.6 per cent; undiagnosed, 10, 3.3 per cent.

Among the 11 pupils with inner ear trouble were 2 with a history of skull fracture and several with a history of other members of the family afflicted with deafness. This group of 11 is considered as afflicted with nerve deafness although about 50 per cent of them had

* The special ear, nose, and throat examination was made under the direction of Dr. Harold G. Kline, consultant for the survey, and Dr. E. P. Hall, whose service aided materially.

FIGURE I

PERCENTAGE OF PUPILS WITH IMPAIRED HEARING WHO WERE FOUND TO HAVE
TONSILS AND ADENOIDS PRESENT

By grade and age

By grade and age

TABLE IV

RESULTS OF SPECIAL EAR, NOSE AND THROAT EXAMINATION OF PUPILS WITH A HEARING LOSS
OF 9 DEGREES AND OVER

	No. of Pupils	Per Cent
Given special ear, nose and throat examination.....	302	
Found to have hypertrophied tonsils.....	201	66.5
Found to have perforated drums.....	21	6.9
Found to have retracted drums.....	142	47.0
Found to have wax.....	54	17.8
Found to have mastoids (operated).....	6	1.9

some middle ear involvement. The 10 cases undiagnosed were recommended for further observation.

In the cases of the 302 pupils who were given the special ear, nose and throat examination recommendations were made as shown in Table V.

TABLE V

RECOMMENDATIONS

Tonsillectomy.....	187
Removal of wax.....	54
Inflation.....	13
Medical attention for purulent discharge.....	33
Further observation.....	15

As a result of this survey we are of the opinion that diseased tonsils and adenoids, causing middle ear catarrh, are mainly responsible for deafness among school pupils. The deafness of 187 pupils, therefore, could have been prevented or materially improved by a tonsillectomy and adenectomy. Ear wax ranks second as a cause of deafness. In this instance the deafness of 54 pupils could be cured by the removal of ear wax.

The condition of 33 pupils suffering from discharging ears could be improved by proper medical attention. In other words, proper

medical attention could restore to normal, or nearly normal, the hearing of approximately 80 per cent of the 302 pupils with impaired hearing.

The groups classified as suffering from inner ear trouble and "undiagnosed" would profit little by medical attention. However, they were referred to their family physician for advice and treatment.

The record of impaired hearing by grade and age shows the highest percentage to have been found in the ungraded class examined at Seymour School. As this class is composed of children who are backward and in some cases not normal mentally, we are not charting it for purposes of comparison.

FIGURE II
PERCENTAGE OF PUPILS WITH IMPAIRED HEARING
By grade and age

Figure II shows the highest percentage of impaired hearing to have been found in the 4th grades where the average age is 10 years.

TABLE VI
PERCENTAGE WITH IMPAIRED HEARING BY GRADE AND AGE

Grade	Average Age	Number Tested	Number with Impaired Hearing	Percentage with Impaired Hearing
3d	8	721	106	14.7
4th	10	867	130	15.0
5th	11	851	113	13.2
6th	12	725	74	10.2
7th	13	677	42	6.2
8th	14	535	27	5.0
Ungraded	12 to 16	43	10	23.2
		4,419	502	11.3

The accompanying tabulations, showing the high percentage of impaired hearing found in the 3d grade at Franklin School with the subsequent gradual decrease in the higher grades, seem to indicate

that a language handicap might be responsible for inability to understand the Audiometer in the lower grades. The population of Franklin School is over 90 per cent Italian.

TABLE VII
PERCENTAGE OF IMPAIRED HEARING BY GRADE AND SCHOOL

School	Grade..... 3 Average Age.... 8	4 10	5 11	6 12	7 13	8 14	Ungraded
	Per Cent	Per Cent	Per Cent	Per Cent	Per Cent	Per Cent	Per Cent
Assumption.....	5.77	3.80	15.20	14.00	3.57	2.63	
Delaware.....	14.09	9.14	10.70	9.40	6.00	3.70	
Franklin.....	38.18	27.00	22.90	10.43	7.00	3.17	
Holy Trinity.....	4.76	8.33	—	—	5.88	4.54	
Sacred Heart.....	8.80	16.80	6.66	17.90	9.90	9.37	
St. John's.....	2.98	5.66	—	—	—	2.44	
Seymour.....	21.00	6.74	12.90	6.60	5.69	7.79	23.2

Impaired hearing in connection with scholarship was investigated at Delaware School. Results were as follows: Total number pupils tested, 854.

Number with Impaired Hearing	Passed	Failures	Passed on Trial
76	65 (85.5%)	6 (7.9%)	5 (6.6%)
Number with Normal Hearing			
778	653 (84.0%)	42 (5.4%)	83 (10.6%)

CONCLUSIONS

The time required to test 40 pupils varies with the grade. Our minimum time was 10 minutes; the maximum 45 minutes.

Experience will enable us to avoid much of the retesting necessary in this survey.

The impaired hearing amounted to 11.3 per cent of all pupils examined in grade schools—slightly higher among girls (12 per cent) than among boys (10.6 per cent).

The amount of impaired hearing in different schools at all ages varies considerably. The minimum amount found was 1.9; the maximum 17.6 per cent.

The highest per cent of impaired hearing was found in the 4th grade where the average age is 10 years.

We believe a language handicap may influence the result of the examination in the lower grades.

Among the 4,419 pupils examined the findings were as follows:

88.6 per cent with normal hearing
9.6 per cent with hearing loss of 9-12 sensation units
1.2 per cent with moderate degree of hearing loss
0.6 per cent with severe degree of hearing loss

Among the pupils requiring special examination it was found that the cause of the impaired hearing was located as follows:

In external ear.....	17.8 per cent
In middle ear.....	75.1 per cent
In inner ear.....	3.6 per cent
Undiagnosed.....	3.3 per cent

Among these pupils 66.5 per cent had hypertrophied tonsils. We believe, therefore, that diseased tonsils and adenoids causing middle ear catarrh are mainly responsible for deafness among school pupils.

Proper medical attention could be expected to restore to normal or nearly normal 80 per cent of the pupils with impaired hearing.

RECOMMENDATIONS

We believe that the examination can be successfully carried on by a nurse properly instructed.

The examinations throughout the city should be given by the same individual in order that the results may be uniform.

All pupils found with a hearing loss of greater than 9 sensation units should be retested.

After retesting any pupils found with a loss of greater than 9 sensation units should be referred to the aurist for further examination.

We would recommend the employment of:

One aurist, part-time, to have supervision and direction of the work; to instruct the nurses in the use of the Audiometer; to give such examinations as are necessary to determine the amount and cause of deafness in those found by previous examination and to determine those who are to be recommended for treatment at dispensary or by their private physician.

One nurse, who shall receive special training in the use of the Audiometer and conduct the preliminary examinations in all the schools. Her salary shall be paid partly by the school board and partly by the health department, so that all the pupils in the city may have the benefit of the examination. She shall report directly to the aurist the results of her examinations.

Our experience and that of others who have carried on similar studies prompts us to recommend that all pupils in the public and parochial schools, not previously examined in each school system, shall be tested by the Audiometer and that thereafter routine examinations for hearing by this method shall be given to all pupils in the third grades each year.

All pupils needing medical care and attention shall be referred to the school nurse for follow-up with definite instructions from the aurist as to whether the child is expected to visit the family physician or be taken to the dispensary.

Some Factors Influencing the Germicidal Efficiency of Alkalies

MAX LEVINE, FELLOW A. P. H. A.

and

J. H. BUCHANAN

Departments of Bacteriology and Chemistry, Iowa State College, Ames, Ia.

BOTTLE washing machinery has long been employed in the carbonated beverage industry, and this mechanical method is rapidly displacing steam sterilization of bottles in the milk plant. In conjunction with bottle washing machines, various chemical solutions are employed. These so-called washing compounds generally consist of caustic soda, sodium carbonate or bicarbonate, trisodium phosphate, sodium silicate, or various mixtures of these alkalies. In some compounds soap or other colloidal substances are also present.

These washing compounds function in two ways: (1) as detergents or cleansing solutions, and (2) as germicides or sterilizing agents. Extravagant claims are sometimes made for the efficiency of the numerous compounds on the market, but there is a lack of knowledge as to the actual cleansing or germicidal powers of these compounds. A dependable method for evaluating quantitatively the relative cleansing or detergent powers of alkaline washing compounds is not as yet available, but their relative germicidal efficiencies may be readily ascertained.

In a number of states and cities, the sanitary regulations specify minimums for temperature, time of exposure, and strength of detergent solutions. A very common requirement, for example, is a temperature of 52° C. for 10 minutes, with 3 per cent alkali calculated as sodium hydroxide. Obviously if 3 per cent alkali gives a satisfactory result at 52° C., in 10 minutes, a shorter period of exposure, or a weaker solution, may be equally or even more efficient at a higher temperature. Then there is the question of the determination of alkali strength. Normal solutions of sodium hydroxide, sodium carbonate and trisodium phosphate (methyl orange titration) are all 4 per cent alkali calculated as sodium hydroxide, but their germicidal powers are very markedly different.

Period of exposure, temperature, concentration, and composition of detergent solutions are important factors, affecting germicidal prop-

erties. A satisfactory and reasonable standard should take these factors into consideration; it should be flexible as respects the interrelations existing between these factors and sterilizing efficiency. Obviously such flexibility cannot be introduced until the relation of composition, concentration, and temperature, to bactericidal powers, are ascertained. It is the purpose of this paper to present a summary of experiments designed to throw some light on these points. For details of the method of preparation of the test culture and technic of the disinfection tests the reader is referred to a previously published paper.¹

A. EFFECT OF TEMPERATURE AND CONCENTRATION OF NaOH

It was the original intention to ascertain "death rates" at various concentrations and temperatures, but this line of attack had to be abandoned in favor of the "death time," for the rates of death were not constant throughout the course of an experiment but progressively increased with the period of exposure. Thus, employing 3 per cent sodium hydroxide at 50° C., it was observed that about 41 per cent of the exposed dried spores were killed in the first 6 minutes; of those remaining, 55 per cent died during the second 6-minute interval, while 94 per cent of those still surviving succumbed in the third 6-minute period of exposure to the action of the alkali.

The results of numerous experiments with various concentrations of alkali ($\frac{1}{4}$ to 5 per cent) at temperatures of 50°, 60° or 70° C., in-

variably showed this increasing "death rate" with progressive periods of exposure.

It appears that there are at least two phases in the killing of bacteria with alkali—penetration of the lethal agent into the cell and the germicidal action of the absorbed alkali. The rates of decrease in bacteria resulting from these reactions did not simulate the well known monomolecular reactions; so "death rates" could not be satisfactorily employed in these studies. On the other hand, the time required to effect reductions of 99.9 per cent of the exposed bacteria, which may be designated "death or killing times," is readily determinable and appears to be much more suitable for comparative purposes.

The observed "killing times" with various concentrations of alkali and at different temperatures are summarized in Table I, and shown graphically in Figure I. As only two points were available at 70° C., the curve for this temperature is indicated by a broken line to designate its tentative character. From these curves the effect of change in concentration of sodium hydroxide or temperature of exposure to the "killing time" may be readily ascertained.

TABLE I

RELATION OF CONCENTRATION OF NaOH AND TEMPERATURE TO TIME FOR EFFECTING REDUCTIONS OF 99.9 PER CENT OF DRIED BACTERIAL SPORES

Temperature Conc. of NaOH	50° C.	60° C. Killing Time in Minutes	70° C.
0.1215 N.	—	—	37.4
0.25 N.	—	46.8	10.7
0.50 N.	41.7	11.7	
0.75 N.	19.8	5.7	
1.0 N.	12.4		
1.25 N.	8.2		

B. EFFECT OF ADDITION OF SALTS ON GERMICIDAL ACTION OF NaOH

A large series of observations on the influence of sodium chloride, sodium carbonate and trisodium phosphate on the germicidal powers of sodium hydroxide has been reported elsewhere.² These studies showed that the salts, when acting alone, had very little killing power on the dried spores of the test organism at 60° C., but when added to caustic soda the sterilizing efficiency of the latter was markedly increased, as may be seen from the summary presented in Table II. The phosphate was not so effective as the chloride or carbonate on a simple weight basis, but if comparisons are made on the basis of the quantity of sodium added, the phosphate would be found more effective than the carbonate and chloride, which are about equal.

Considering the fact that these salts showed but slight germicidal properties at 60° C. when acting by themselves, their marked effects

are attributed to their influence on the hydroxide. The presence of sodium chloride, carbonate and phosphate enhances the germicidal properties of sodium hydroxide. No appreciable changes in pH of 1.0 per cent sodium hydroxide were observed on addition of the salts studied. It is suggested that the increased sterilizing action is due to an increase in undissociated sodium hydroxide which penetrates the cell, or to a decreased water solubility (change in partition coefficient) of the hydroxide which is forced into the bacterial phase of the water-bacteria mixture.

TABLE II
EFFECT OF SALTS ON GERMICIDAL EFFICIENCY OF NaOH AT 60° C.

Alkali	Killing Time in Minutes
1% NaOH	42.5
1% NaOH + 1% NaCl	
1% NaOH + 2% NaCl	30.6
1% NaOH + 3% NaCl	23.4
	19.9
1% NaOH + 1% Na_2CO_3	
1% NaOH + 2% Na_2CO_3	29.0
1% NaOH + 3% Na_2CO_3	21.9
	20.1
1% NaOH + 1% $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$	
1% NaOH + 2% $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$	34.9
1% NaOH + 3% $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$	28.1
	24.7

If the killing times in Table II are plotted against the per cent of added salts, curves are obtained (see Figure II) from which the effects

of these salts on the germicidal properties of 1.0 per cent sodium hydroxide at 60° C. may be read off.

C. RELATION OF NORMALITY AND pH TO GERMICIDAL EFFICIENCY OF ALKALIES

For the purposes of control of alkali detergent solutions, it is essential to have some simple but adequate method available for the plant operator. It was formerly customary to employ the hydrometer or specific gravity of the solution. This is obviously not dependable either as a measure of alkalinity, detergency, or germicidal efficiency, for in the course of a day's operation, the specific gravity might actually increase, due to the accumulation of soluble salts from the washed bottles, while the actual alkali content, and consequently the detergent and germicidal properties of the solution, would decrease because of the neutralizing substances removed from the bottles. The hydrometer is gradually being replaced by alkalinity (expressed as per cent caustic soda) determinations and it has more recently been suggested that the pH might serve as an index.

A few observations on the comparative germicidal efficiencies of alkalies of the same normality as well as at the same pH are given below.

1. *Comparison of different alkalies at the same normality*—It was found necessary to employ a temperature of 70° C. in order to effect a reduction of 99.9 per cent of the exposed bacteria with a normal solution of sodium carbonate,* within a reasonable time. At this temperature, the killing times determined for normal solutions of sodium carbonate and trisodium phosphate were 118 and 5 minutes respectively, while that for a normal sodium hydroxide solution was estimated from Figure I at about 0.6 minute. The pH (expressed as at 30° C.) of these normal solutions were 11.35, 12.15 and 13.43 for the carbonate, phosphate, and hydroxide, and the corresponding concentrations by weight were 5.3, 19.0 and 4.0 per cent.

It is evident that titrable alkalinity (expressed as per cent caustic soda) is not a direct measure of germicidal efficiency of different alkalies. At first thought, it might appear that the pH value would be a preferable index, as the alkali with the highest pH was most efficient, but a study of the germicidal efficiencies of different alkalies at the same pH shows distinctly that this determination is also unsatisfactory.

2. *Comparison of different alkalies at the same pH*—In Table III are shown the periods required to kill 99.9 per cent of the exposed

* All titrations made with methyl orange.

bacteria at 70° C., employing different alkalis at the same pH. It will be observed that there is no direct relation between the pH and killing times for different alkalis.* Thus trisodium phosphate was not only much more efficient than sodium hydroxide at the same pH (pH 12.15), but it was also a much better germicide than sodium hydroxide at a distinctly higher hydroxyl ion concentration (pH 13.0).

TABLE III

RELATION OF pH TO GERMICIDAL EFFICIENCY OF DIFFERENT ALKALIES AT 70° C.

pH	Alkali	Killing Time
11.35	Na ₂ CO ₃	118 minutes
11.35	Na ₃ PO ₄ ·12H ₂ O	163 minutes
11.35	NaOH	220 minutes
12.15	NaOH	36 minutes
12.15	Na ₃ PO ₄ ·12H ₂ O	5 minutes
13.0	NaOH	12 minutes
13.0	Commercial alkali	6.3 minutes

At a given hydroxyl ion concentration, sodium carbonate was most efficient, followed by the phosphate and hydroxide. This is just the reverse order from that which was observed when comparing these alkalis on a normality basis.

For a given alkali, the germicidal properties increase with concentration on both the normality or hydroxyl ion basis, but neither of these indices is a direct measure of the relative disinfecting efficiencies when comparing different alkalis.

D. ON THE CHOICE OF AN INDEX FOR THE CONTROL OF ALKALINE BOTTLE WASHING SOLUTIONS

The ideal index would be one which bears a direct relation to the detergent and germicidal powers of all compounds used in bottle washing and which may be easily determined with a reasonable degree of reliability by the plant operator. In the selection of an index, consideration should also be given to the nature and composition of washing compounds generally employed. In view of the lack of suitable and accepted methods for quantitatively estimating detergent properties, the choice of an index must be made, at least for the present, on the basis of relation to germicidal properties and reliability of determination. The hydrometer or specific gravity, the pH, and the titrable alkalinity (expressed as caustic soda) have either been employed or suggested as indices.

The objections to the hydrometer test have already been stated. The specific gravity of a cleaning solution may remain constant or even increase simultaneously with a reduction of alkalinity due to accumulation of neutralizing substances, so that this index is unsuitable.

The pH is too delicate an index for satisfactory use in the hands of the plant operator. Considering sodium hydroxide, it will be observed from Figure I that the "killing times" for 1 and 3 per cent solutions at 60° C. were about 47 minutes and 6 minutes, and their reactions were pH 12.99 and pH 13.32 respectively. A difference of 0.33 in pH was accompanied by a variation of about 800 per cent in "killing time." The determination of pH in the vicinity of pH 13 is very difficult. With carefully calibrated instruments and pure solutions variations of 0.1 were not uncommon for trained observers. An error of probably not less than pH 0.2 would have to be expected if colorimetric methods were to be employed by the plant operator, with turbid and colored solutions. Such an error would be equivalent to 2 per cent sodium hydroxide or about 400 per cent in anticipated killing time. The titrable alkalinity would be subject to less error in the hands of the operator.

Most washing compounds consist of mixtures of sodium hydroxide with carbonate or phosphate. In Figure II it is shown that the "killing time" decreased as the quantity of carbonate or phosphate added to the hydroxide increased, but the pH of the mixtures remained constant, as far as was determinable. The titrable alkalinity increased with added carbonates and phosphates and was therefore better correlated with germicidal efficiency than the pH of the mixtures employed.

It appears, therefore, that for washing compounds and concentrations actually employed, the alkalinity expressed as sodium hydroxide is, at present, a more suitable and reliable index of germicidal efficiency than pH, although it is not the ideal index. The determination of the free caustic as well as total alkalinity is essential for evaluating the germicidal properties of washing solutions.

With the aid of Figures I and II it is possible to develop sterilizing efficiency tables for hydroxide carbonate and hydroxide phosphate mixtures at 60° C., in terms of sodium hydroxide, on a titration basis, but this cannot be done on a pH basis.

SUMMARY

1. A technic is reported for ascertaining the relative germicidal efficiencies of strong or concentrated alkalies.
2. The exposed bacteria did not die off at a constant rate, but on the contrary, the death rates increased with the periods of exposure. These rates are therefore considered unsatisfactory for comparative purposes.
3. The "killing time" for 99.9 per cent of the exposed bacteria is considered a suitable, determinable, and desirable criterion of the relative germicidal efficiencies of the alkali solutions studied.

4. For a given alkali, the germicidal efficiency increases with its normality and hydroxyl ion concentration, but neither of these determinations can be considered a suitable index of the comparative sterilizing powers of different alkalies.

5. At the same normality, the alkalies rank in the order: (1) sodium hydroxide, (2) trisodium phosphate, and (3) sodium carbonate with respect to sterilizing efficiency.

6. At the same hydroxyl ion concentration (pH) the order of sterilizing efficiency is reversed, namely, (1) sodium carbonate, (2) trisodium phosphate, and (3) sodium hydroxide.

7. The addition of sodium chloride, sodium carbonate, or trisodium phosphate to sodium hydroxide markedly reduced the "killing time," though it did not measurably affect the pH of the caustic solution.

8. The germicidal efficiency of alkalies is not a direct function of the hydroxyl ion concentration but is affected markedly by other factors.

9. The undissociated sodium hydroxide may be the controlling factor in the germicidal powers of alkalies.

10. Considering the washing compounds as actually employed (sodium hydroxide and mixtures of the hydroxide with carbonate or phosphate), the alkalinity expressed as caustic soda (normality) is a more suitable and reliable index than the pH value.

11. Curves are presented showing the relation of temperature and concentration to germicidal efficiency of sodium hydroxide, and the effect of the presence of sodium chloride, carbonate and phosphate on this efficiency.

Supervision of Milk Supply in Cuba

A DECREE establishing a special government bureau for supervision of the milk supply throughout Cuba has been signed by the President. Detailed regulations on this subject have been prepared by a special committee and will be submitted to the President for his signature. The decree orders that the next budget include an appropriation for carrying out this work.—*El Mundo*, Habana, July 2, 1928, p. 1.

A Publicity Campaign of National Scope^{*}

H. E. KLEINSCHMIDT, M.D., FELLOW A. P. H. A.

National Tuberculosis Association, New York, N. Y.

SEVERAL years' experience in conducting the Christmas Seal sale has taught tuberculosis associations a successful technic of organized publicity. While the seal sale undoubtedly has some educational value, its primary purpose is to raise funds. In 1928, tuberculosis associations of the United States agreed to unite in a nation-wide publicity campaign which should have for its sole objective the education of the public in at least one important principle of tuberculosis prevention.

In planning the campaign, it was early recognized that, whatever the message, it must be simple and concrete. After careful consideration of some twenty suggestions, it was decided to select as the central theme the importance of discovering tuberculosis in its early stages. This concept was built around the slogan, "You May Have Tuberculosis," with the emphasis on "You," followed by the specific appeal to "Let Your Doctor Decide." The slogan was supplemented in most of the publicity material by a list of danger signs; namely, Too easily tired, Loss of weight, Indigestion, Cough that hangs on: a list of symptoms selected by a number of clinicians whose opinions had been sought. The message was to be addressed primarily to adults. The ultimate objective was to acquaint everyone with the danger signs of tuberculosis; to motivate all who were in doubt about their health to seek medical advice; and to bring to the attention of the medical profession the importance of discovering the disease in its early stages. There is nothing new in this idea, but by concentrating on it for a brief but definite period, it was hoped that the cumulative effect of past educational efforts might be crystallized.

The publicity committee which sponsored the slogan was not blind to the fact that its appeal was one of fear, a motive which has of late fallen into disrepute. (More properly it might be maintained that the appeal was one of cautiousness.) It also considered frankly the criticism that the listing of symptoms savored of quackery; but con-

* Report of the Early Diagnosis Campaign Conducted by Tuberculosis Associations.

cluded that the questionable end achieved by the quack did not necessarily condemn the means. The committee recognized, too, that the message emblazoned on broadside and billboard might arouse much needless apprehension and thus sow the seeds of neurasthenia, where it had hoped to scotch tuberculosis. But against these several objections was weighed the obstinate fact that today, after some two decades of continuous propaganda, the majority of patients who are diagnosed as tuberculous come to the doctor for the first time only after the disease is well advanced, the grave significance of which is apparent to the public health worker as it is to the medical practitioner. Therefore, a message with an elemental appeal, directed straight at the reader, including a frank listing of danger signs and the direct advice to seek medical aid, seemed justified.

March, 1928, was selected as the month when the campaign was to be carried on. Practically all state and affiliated tuberculosis associations agreed to participate according to their abilities, and the National Tuberculosis Association assumed the responsibility of leadership. The material created for the purpose included the following:

- A poster designed by Ernest Hamlin Baker, showing a physician examining a patient with bared chest. This was used also as a posterette, car card and window display.

- A 24-sheet billboard designed by F. G. Cooper, featuring the slogan and the double-barred cross, and listing the symptoms.

- A 4-page circular containing brief information and descriptions of the early symptoms.

- A 6-page folder for physicians, entitled "An Appeal to the Medical Profession."

- Newspaper articles, including feature stories and illustrations.

- Special articles on early diagnosis, written by well-known clinicians, offered for publication to medical and public health journals.

- Two motion pictures, one for lay audiences called "Delay is Dangerous"; another for medical groups, "The Doctor Decides."

- Electrotypes for use in newspapers, house organs and magazines.

- For the guidance of secretaries of tuberculosis associations, a special manual of instructions for securing publicity was printed, while a mimeographed periodical called "Diagnostigrams" helped to exchange ideas and to feed the fires of enthusiasm.

Roughly, the National Association invested about \$68,860 in the campaign, of which about \$30,000 was returned in the form of purchases from its affiliated associations. This figure includes the production cost of certain materials, such as motion pictures, and the art work for posters, which together exceeded \$24,000. The National Association gave free to its affiliated associations material valued at several thousand dollars and distributed independently almost \$1,000 worth of printed matter.

State and local associations also produced much of their own material, gave lectures and radio talks, arranged for motion picture showings, and furnished newspaper copy. Commercial organizations, fraternities, societies and insurance companies entered into the spirit of the campaign, some printing their own material or carrying publicity through their magazines, others distributing the material furnished by the tuberculosis society. The Metropolitan Life Insurance Company devoted its expensive and widely read advertising page during the month of March to the early diagnosis of tuberculosis.

Equally important as the effectiveness and persuadability of the publicity matter is the manner in which it is distributed and used. It soon became evident that some associations entered into the campaign with vigorous spirit, while a few merely drifted or were pulled along by the current. To gauge the effectiveness of a publicity effort by a measure of the materials produced, even if that were possible, would be misleading, for the effort necessary to make the publicity material "work" cannot be measured. As a very rough index, however, of the enterprise of associations, a tabulation was made, showing the amount of material furnished to each state. When the supplies purchased by states were reduced to a per capita figure, it was found that the largest amount of publicity material purchased by any one state was equal to \$2.14 per 1,000 population, while the state at the bottom of the list purchased \$.08 worth of material per 1,000 population. The average value of material secured from the National Association by the 54 state and affiliated associations on a per capita basis of 1,000 was \$.332. This figure represents only the bare cost of material and, since only a wild guess is possible, may legitimately be multiplied by three in order to estimate the total cost, including overhead, of the campaign; which in that case would be equivalent to \$1.00 per 1,000 population, or one mill per person.

Newspaper clippings which deluged the office shortly after the campaign opened gave some indication of the vast amount of publicity on tuberculosis which appeared throughout the country. Some associations measured the newspaper space secured. Michigan, for example, reported 529 columns; New Jersey 189; Indiana 100; Minnesota 100; West Virginia 88; St. Louis 500 columns; to mention but a few.

The motion pictures were distinctly successful. Of the film for lay audiences 214 copies were sold. In many cities the film was used as part of the regular program of motion picture theatres. Some characteristic comments abstracted from the reports are these: Booked solid until April 16—Shown in 10 of the leading theatres—Shown in

30 schools, 50 factories and 14 other groups—Very popular especially in commercial houses—Booked solidly to beginning of May—State Board of Health is to show "Delay is Dangerous" in every county of state. The film for medical audiences was equally well received and provided an excellent opportunity for tuberculosis associations to co-operate with medical societies. Incidentally one of the valuable by-products of the campaign is that it has given associations a chance to join hands with the medical profession. The film was not intended, of course, to teach doctors how to make a diagnosis but it did open the door for further discussion and where an actual demonstration of how to make a thorough physical examination was combined with a film showing, the effect was a happy and a valuable one.

Another rough index for measuring the effort and the results of the campaign was derived from reports made to the National Association by its affiliated associations on clinic attendance. These do not lend themselves to tabulation which would have exact statistical value, but a hasty sampling indicates that in one respect at least the publicity hit its target. "Let Your Doctor Decide" was the specific advice emphasized. The severest test that might be applied was, how many, if any, persons actually visited the doctor as a direct result of the educational campaign. A complete answer cannot, of course, be given; but every association that reported mentioned that a decided increase in clinic attendance had been noted. A few quotations are these:

Clinics reported an increase in attendance over last year in March of 30 per cent.

Business of health center increased.

Clinics overcrowded and new clinics started in rural schools.

Material increase in clinics, necessitating holding of special clinics.

Created waiting list for county sanatorium.

Clinic attendance exceeded expectations, resulting in discovery of 15 active cases.

Clinic attendance for month is 40 per cent higher than for March, 1927, and is 16 per cent higher than it has ever been.

Discovery of largest number of early and curable cases of tuberculosis in the history of the work of the association during a one-month period.

New tuberculosis patients doubled in March.

Since the educational message included the direct advice to consult the doctor, an attempt was made to learn what, in general, the medical profession thought of the campaign and whether or not they had noticed an increase in the number of private patients who consulted them about tuberculosis. Opinions which had been gleaned here and there from representative medical men were nearly all favorable. To secure more specific information, letters were written to the several hundred physicians identified with the tuberculosis movement through-

out the country. After eliminating from the replies those that were unsatisfactory, for such reasons as that the writer was not in practice or did not treat tuberculosis, there remained about 200 letters which expressed definite opinions or furnished concrete information. All but 2 replies were distinctly favorable and most of them strongly endorsed the campaign. About 50 stated that there had been an increase of private patients asking advice about tuberculosis, while about 30 noted no increase in patients. Twenty-four replies furnished figures showing an increase in clinic patients and 14 demonstrated an increase in sanatorium admissions.

Here are a few characteristic quotations from the letters from physicians:

The campaign has been of value in the early recognition of tuberculosis.

By far the best thing that has ever been done in this place by the local tuberculosis society.

Your Early Diagnosis Campaign has real value, particularly in bringing early cases of tuberculosis to us.

The campaign in Indiana has had a very marked effect and should be carried on again.

The bringing together of physicians and different groups was the best single result of the campaign.

This campaign has really done an immense amount of good.

While comments about the campaign were almost universally favorable, some unfavorable opinions were voiced in scattered places by the press and otherwise. These may be summarized as follows:

1. That the appeal, particularly the appeal to fear, was objectionable. (Sometimes a shock is necessary to stir people out of their lethargy. The second part of the slogan "Let Your Doctor Decide" suggested how the fear of tuberculosis might be brought out into the open and removed if it were groundless.)

2. That doctors generally were not able to diagnose tuberculosis when cases were sent to them. (Like most generalizations, this is an unfair one. Through medical articles, a motion picture and special publications, opportunity was given doctors to review and increase their knowledge about tuberculosis.)

3. That tuberculosis associations, by advocating the slogan, "Let Your Doctor Decide," became nothing more or less than press agents for the medical profession. ("Press agents" is a hard word—but let it pass. What sounder advice could be given one in doubt about his health than to consult a physician?)

4. That the advertising of symptoms is bad psychology and also that it is too closely imitative of quackery and patent medicine methods. (That the giving of specific information is bad psychology is open to question; that it does tend to lead to action is not. Because the quack uses certain methods to attract customers does not necessarily condemn the methods.)

5. That the bared chest of the man in the Baker poster is indecent and not proper for showing before mixed audiences of boys and girls. (Life is too short to answer this objection seriously. Emphasizing the bared chest was of immense value in driving home the idea that a good physical examination cannot be made through a coat and vest.)

Worthy of careful consideration was a friendly criticism made by several representatives of health associations which promote some particular phase of public health other than tuberculosis and by spokesmen for the medical profession. It was to the effect that tuberculosis should not be emphasized to the exclusion of all else. A patient should not be examined with the set purpose of turning up some one particular disease or condition, but to discover whatever pathology may exist, or, better still, to sum up the health capital of the examinee. In other words, the periodic health examination should have been urged rather than a search for tuberculosis.

This is a pertinent criticism. It may be answered in part by submitting that most general practitioners are not yet sufficiently interested in health in the abstract to encourage periodic health examinations. The physician of today is interested primarily in pathology and regards health as something to be recovered rather than to be achieved and maintained. Probably more progress will be made if doctors approach the patient from the point of view of some definite disease or pathology, such as tuberculosis. By gradually broadening the emphasis, doctors may in time become interested in examining the entire body, not with some definite pathology in mind as the target but for the purpose of evaluating the health capital of the examinee. The present campaign was a mere start. If continued year by year, it is possible that the educational campaign may become broadened in scope and power and finally resolve itself into a vigorous periodic health examination campaign.

The Early Diagnosis Campaign carried on by tuberculosis associations in 1928 may be deemed a success because:

1. Every state tuberculosis association coöperated.
2. Pertinent facts about tuberculosis were widely spread.
3. Many persons were persuaded to consult the doctor; clinic attendance and sanatorium admissions were increased.
4. Public health (volunteer and official) and medical groups united in the pursuit of a common objective.
5. The way was paved for more publicity.

Tuberculosis associations are planning another educational campaign for 1929. At least one objection of this year's campaign, it is believed, will be met by the new slogan: Tuberculosis—Early Discovery, Early Recovery (list of symptoms)—Let Your Doctor Decide. This message is broader, more hopeful, of a more positive appeal, and lends itself well to pictorial expression.

The Carbon Monoxide Hazard in City Streets*

JOEL I. CONNOLLY, FELLOW A. P. H. A., MATHEW J. MARTINEK, and JOHN J. AEBERLY

*Chief, Bureau of Sanitary Engineering; Senior Sanitary Chemist; and Head,
Division of Ventilation and Industrial Sanitation;
Department of Health, Chicago, Ill.*

A REPORT of a new form of homicide recently made its appearance in the public press. It was reported that the victim was bound and placed near the exhaust pipe of an automobile so that he was forced to inhale the poisonous fumes of the running motor. Possibly this novel method of destruction of human life was suggested by the all too frequent reports of deaths from carbon monoxide poisoning due to operating automobile motors in closed garages.

It is perhaps inevitable that the increase in the number of vehicles using internal combustion motors upon city streets should contribute more and more to air pollution, unless some revolutionary change in motor design is made.

As the buildings increase in height, the population going to and from them likewise increases, necessitating greater transportation facilities, including motor driven vehicles which further contribute to air contamination. The number of persons regularly exposed to the effect of engine exhaust gases is also greater.

The careful studies being made, such as that for the ventilation of the Holland Vehicular Tunnel under the Hudson River, indicate that responsible officials are alive to the potential danger of the present situation. Such a realization, however, has not yet come to the public generally. A single motor car which is throwing out a cloud of visible and malodorous fumes of burning oil is more often the subject of complaint to the health department than are a thousand normally operated cars on the same street, although the combined effect of the latter may be far more injurious to health than the former. This is not surprising, in view of the fact that carbon monoxide, the deadly component of exhaust gases, is not evident to sight, taste nor sense of smell. If carbon monoxide had an offensive odor there would be far

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 15, 1928.

fewer deaths from it, as people would open their windows or install ventilation systems to get rid of it.

During the three years, 1925 to 1927, inclusive, 133 deaths occurred in Chicago from carbon monoxide poisoning. It is a proper function of a health department not only to prevent needless and premature deaths, but also to prevent non-fatal illness and sickness. Such minor illness may not necessarily keep a man from his work but nevertheless impairs his productivity and usefulness. Acting upon this principle, the Bureau of Laboratories and Research, and the Bureau of Sanitary Engineering of the Chicago Department of Health, in 1926, 1927, and 1928, undertook a comprehensive study of air pollution by carbon monoxide in the streets of the city, under the direction of the Commissioner of Health.

A review of the literature established the fact that definite symptoms of carbon monoxide poisoning may occur from long exposure to low concentrations of the gas as well as from a brief exposure to high concentrations.

Sayers and Yant¹ aver that when a given blood saturation has been acquired by long exposure to low concentrations of carbon monoxide, the symptoms and after effects are more severe than when that same saturation is the result of a short exposure to a higher concentration.

The former type of poisoning, though not acute, gives rise to dizziness, headache, lassitude, nausea and similar symptoms, while the latter or acute type is likely to be immediately fatal.

There is a great variation in individual tolerance to chronic poisoning by carbon monoxide, children being more susceptible to such poisoning than adults, and women apparently are more susceptible than men.² An illustration of differing individual susceptibility is reported by A. M. Stevens, M.D.³ A 7-weeks-old baby died of carbon monoxide poisoning, having a saturation in the blood of 18 per cent. In the baby's bedroom a small leak was found in a gas fixture. The mother who had been in the room almost constantly was poisoned only enough to suffer from headache.

In large cities many susceptible girls are employed for seven to eight hours a day in the atmosphere of the street level, in positions as salesgirls, stenographers, waitresses and in similar capacities. Even their lunch periods are usually spent in the same kind of air. Obviously, constant pollution of the air with carbon monoxide of sufficient concentration will tend to reduce their chances of having robust health, and vigorous vitality, even though definite symptoms of poisoning may not be recognized. Men similarly exposed for hours at a time, as in the case of traffic policemen, have been found to

show a high content of carbon monoxide in the blood. Wilson, Gates, Owen, and Dawson⁴ report the blood findings of 14 policemen, after 8 hours of traffic duty in Philadelphia. Six of the 14 showed an absorption of carbon monoxide of between 20 and 30 per cent of saturation—more than the amount that caused the death of the baby previously referred to. Although death of male adults does not usually occur until a blood saturation of 60 to 70 per cent is reached,⁵ the 20 to 30 per cent found in the blood of these traffic policemen is sufficient to cause headache, dilation of cutaneous blood vessels, throbbing in the temples and, in some individuals of low tolerance, weakness, dizziness, visual disturbances and nausea.

Having these facts in mind, the Commissioner of Health initiated arrangements for a survey of the air of the streets of typical districts of Chicago, and 690 street air samples in all were collected in the survey. Some of the streets selected for sampling were carlines, avoided by automobile traffic; others were automobile boulevards from which heavy and slow moving traffic was excluded; some were in residential sections; some in manufacturing and industrial regions; and still others in the downtown area, locally known as the loop. Sometimes the air samples were taken at the corners of intersecting streets, to get the effect of traffic from both directions, and others were collected midway between. In other words, an effort was made to get a cross-section of the city streets and to avoid concentrating upon any one type of street or area.

The samples were collected at the curb instead of in the middle of the street, because the greater number of the people exposed are upon the sidewalks and in the adjacent offices and stores. Taxicab drivers, streetcar men and others engaged in similar pursuits which require them to spend many hours in the middle of the street form but a small proportion of the total population to be considered.

For purposes of uniformity, samples were collected at a level of three feet above the sidewalk. This is a convenient height for sampling and also is near the breathing zone of children, who constitute the most susceptible age group. Of course, many variables were inevitably present, such as temperature, humidity, wind velocity, and direction as well as variations in the amount and kind of traffic passing at the time of sampling. Observations of these uncontrolled variables were recorded whenever a sample of air was taken, as an aid in correlating the data. No attention was paid to other than automobile traffic. The number of automobiles passing during five minutes was recorded, together with the other observations, upon a special form prepared for the purpose.

Of the 690 samples, 41 were collected upon the lower level of Wacker Drive, a two-level street along the Chicago River. The remaining 649 samples were all taken on streets without overhead obstruction.

METHOD OF EXAMINATION OF SAMPLES

The air samples were collected by displacement in half liter Thoerner's gas sampling bottles. At first a saturated solution of common salt (sodium chloride) was used in the sampling bottles to avoid dissolving any of the constituents of the air. Experience later indicated that there was no material advantage in using salt solution in this study, so water was substituted. The samples were taken to the laboratory and analyzed by means of a modification of the iodine pentoxide method devised in our laboratory.*

The method was chosen only after an exhaustive study of other methods, each possessing certain advantages and disadvantages for the purpose intended. By this technic the carbon monoxide is oxidized to dioxide by iodine pentoxide, and iodine is liberated. Accurate measurement of the latter by titration with sodium thiosulphate solution makes possible the calculation of the amount of carbon monoxide.

METHOD

Certain safeguards must be employed to exclude errors. The sample of air first passes through a bath of concentrated sulphuric acid, at room temperature, to remove part of the moisture, then through a bath of the same acid, maintained at a temperature of 150° C., which takes out heavy hydrocarbons, much of unburned gasoline and methane. It then passes through another bath like the first, which serves to condense acid fumes liberated in the hot bath. Unburned gasoline and hydrogen are removed by activated charcoal and the remaining moisture is absorbed by a series of dehydrating agents, consisting of soda lime, solid potassium hydroxide, and an absorbent called "dehydrite" (magnesium perchlorate trihydrate—Smith) in the order named.

After this preliminary treatment, the carbon monoxide in the sample reacts with the iodine pentoxide at a constant temperature of 150° C. in a thermostatically controlled chamber, forming carbon dioxide and iodine. The latter is absorbed in 10 per cent potassium iodide, after which the air passes to a meter and manometer for the purpose of measuring the amount and pressure respectively. The iodine pentoxide is seasoned before use by heating at 215° C. until no more free iodine is liberated, a process ordinarily requiring several weeks. A micro-burette fitted with a platinum hypodermic needle is used for titrating the iodine with one-thousandth normal thiosulphate solution. The needle makes it possible to get very small drops, thus increasing the accuracy of the titration—an essential factor when dealing with low concentrations of carbon monoxide.

After the analysis, the apparatus is washed with seven times the volume of air

* A detailed description of this method will later be published by Mathew J. Martinek and William C. Marti, who devised the modifications.

TABLE I
AIR SAMPLES CONTAINING VARIOUS AMOUNTS OF CARBON MONOXIDE

Concentration in Parts per 10,000	Number of Samples	Per Cent of Total	Per Cent Having Higher Concentrations
0.00-0.04	66	10.2	89.8
0.05-0.10	120	18.5	71.3
0.11-0.20	121	18.6	52.7
0.21-0.30	105	16.2	36.5
0.31-0.40	85	13.1	23.4
0.41-0.50	60	9.2	14.2
0.51-0.60	32	4.9	9.3
0.61-0.70	22	3.4	5.9
0.71-0.80	16	2.5	3.4
0.81-0.90	13	2.0	1.4
0.91-1.00	9	1.4	0.0
Total	649	100.0	

sampled, taken from an uncontaminated source, as a control. Pipes to the outside air, approximately 100 feet above street level, are used to secure this air, rather than run the risk of using laboratory or street level air. Test runs made with air containing various known amounts of carbon monoxide have demonstrated that this method is accurate for quantities of carbon monoxide down to as little as 0.1 part of carbon monoxide to 10,000 parts of air. Blank determinations, using the same amount of air as used in flushing the apparatus, are also made to insure accurate results.

As would naturally be expected from the wide distribution of sampling points, the greater number of samples show low concentrations of carbon monoxide. Omitting from our consideration for the moment the samples from the lower level of Wacker Drive, it is found that 85

FIGURE I

per cent of the other 649 samples examined showed 0.5 part or less per 10,000 parts of air, and 63 per cent showed 0.3 part or less per 10,000. Table I and Figure I indicate the proportions of the total number of samples containing various amounts of carbon monoxide.

The average concentration for the city, of all the samples, was 0.31 part of carbon monoxide per 10,000 parts of air. If this amount were uniformly distributed, there would be, of course, little cause for apprehension. Table II and Figure II show that such is not the case, but that the poisonous gas is concentrated along the boulevards.

TABLE II
CARBON MONOXIDE IN VARIOUS KINDS OF STREETS

Concentration in Parts per 10,000	Residential and Industrial Streets % of Samples	Traffic Streets % of Samples	Boulevards % of Samples
0.00-0.10	71.0	26.5	8.4
0.10-0.20	16.0	28.0	10.4
0.20-0.30	10.0	25.4	9.6
0.30-0.40	2.0	10.6	21.6
0.40-0.50	1.0	6.1	16.8
0.50-0.60	0.0	1.9	10.8
0.60-0.70	0.0	1.1	7.6
0.70-0.80	0.0	0.0	6.4
0.80-0.90	0.0	0.0	5.2
0.90-1.00	0.0	0.4	3.2
	<hr/> 100.0	<hr/> 100.0	<hr/> 100.0
Average concentrations (Parts per 10,000)	0.125	0.250	0.476

Figure II shows the distribution of samples by concentrations upon three types of streets: (1) residential and industrial streets, (2) traffic and carline streets, and (3) automobile boulevards. The relative amount of the pollution of air with carbon monoxide upon the three classes of streets, as measured by the average concentration of samples in each group, indicates that the boulevards have approximately twice the air pollution of the traffic streets and four times that of the residential and industrial streets.

The concentration by districts was greatest downtown in the "loop" (0.53 part per 10,000), where there is also the greatest density of persons exposed. To the east lies Lake Michigan, upon which no samples were taken. Densely populated areas surrounding the loop on the other three sides showed from 40 to 57 per cent as much carbon monoxide in the air as did the loop district (0.21 to 0.30 part per 10,000), while other portions of the city more remotely situated and less thickly inhabited revealed only 28 to 34 per cent as much as in the business center (0.15 to 0.18 part per 10,000).

FIGURE II

A definite correlation, as was confidently expected, was found to exist between the number of automobiles passing the sampling stations at the time of collecting the samples and the amounts of carbon monoxide found to be present. Table III shows that as the number of cars increased, the carbon monoxide followed the same upward trend.

TABLE III

SHOWING INCREASE IN CARBON MONOXIDE CONTENT WITH GREATER AUTOMOBILE TRAFFIC

No. of Automobiles Passing Sampling Station in 5 Minutes of Test	Carbon Monoxide Parts per 10,000
0	0.10
1-50	0.17
50-100	0.27
100-200	0.35
200-400	0.51
400-1000	0.64

We may consider that the 0.1 part per 10,000 present when no automobiles were passing is a residual amount. The amount of carbon monoxide less this residual amount varies approximately as the logarithm of the number of automobiles passing during 5 minutes.

On busy boulevards a pronounced variation was found in the carbon monoxide content of the air at various hours of the day, reaching peaks during the rush hours. Figure III shows the hourly fluctuations upon Michigan Boulevard in the portion closest to the loop, namely between the Chicago River and Harrison Street. Maxima occur during the morning and evening rush hours, 8:00 to 9:00 a.m., and 5:00 to 6:00 p.m., respectively, and also between 11:00 a.m. and 12:00 m., and between 1:00 and 2:00 p.m. The latter two peaks coincide with increases in automobile traffic.

CARBON MONOXIDE AND TWO-LEVEL STREETS

Two-level streets are not yet in very common use, but prophets are not lacking who predict that the future will bring many of them in congested centers. The lower level of Wacker Drive is open to the river on one side and therefore conditions are not so bad as if both sides were enclosed. Nevertheless the primary sense impression of the air on the lower level is frequently far from good, especially when traffic is held up owing to bridges being opened for the passage of vessels.

Forty-one air samples taken there and on the lower level of Michi-

FIGURE III

gan Boulevard adjoining at various times of the day and on six different days have been examined. But one sample showed less than $\frac{1}{3}$ part per 10,000 of carbon monoxide, whereas three showed more than 1 part. The maximum was 1.33 and the average 0.620 part per 10,000. This average is higher than that of boulevards (0.476) or of the loop district (0.530).

Fortunately there are relatively few people who spend many hours a day on the lower level. The Department of Health has refused permission to use that level as a source of air supply for stores, offices or similar spaces in adjoining buildings.

CONCLUSIONS

1. In general, the concentration of carbon monoxide in the air of city streets other than automobile boulevards is insufficient to constitute a serious public health hazard.

2. At times the air of automobile boulevards contains enough carbon monoxide to menace the health of those exposed over a period of several hours, particularly if their activities require deep and rapid breathing.

3. Automobile boulevards at street level and the lower level of double-decked streets do not afford a satisfactory source of air supply for habitable rooms.

4. Studies should be continued to determine the relationship existing between the concentration of carbon monoxide in boulevard air and the extent of blood saturation and injury to health of people continuously exposed to such air for considerable periods of time.

5. Studies of the necessity for mechanical ventilating systems should be a part of the design of all double-decked streets for use by automobiles.

6. Idling of motors on the streets should be restricted to a minimum. If idling cannot be prevented, at least it should not occur near air intakes for ventilating systems.

7. The stack effect of tall buildings in the downtown area in promoting circulation of air is not enough to compensate for the greater production of carbon monoxide in this area and for the interference of buildings with the flushing action of the wind. The result is a higher concentration of gas in the region where most of the people congregate than in the less densely inhabited areas.

8. The possibility of injurious effects, upon the health of susceptible age groups or individuals, from carbon monoxide in concentrations below 1 part per 10,000 should be carefully investigated in order that the public health importance of this gas in street air may be appraised.

Porto Rico and Its Milk Problems

P. MORALES OTERO, M. D.

Director of the Biological Laboratory, Department of Health, San Juan, P. R.

THE milk supply is a serious problem in practically all tropical countries. In addition to climatic conditions which greatly increase the difficulties of maintaining a high bacteriological standard, there are other problems not so readily appreciated by the sanitarian of the temperate zone.

Despite the difficulties, the milk industry in Porto Rico has shown marked improvement in the past ten years. Several factors have influenced the change:

1. Sanitary supervision and inspection
2. Enforcement of a chemical and bacteriological standard with routine examination of samples
3. Improvement of cattle breeds and of operative methods

Conditions in Porto Rico some 15 years ago as regards the milk supply are well described by Lucas, Sárraga and Benítez in an article published in 1913. The following is a summary of the situation as it then appeared to them:

The native cow is of no particular breed but is a mixture of different strains introduced into the island from time to time. The object of cattle raising here is not to produce meat or milk but to provide oxen for draft animals. The cow as a milk producer has been ignored. And no attention has been given to the improvement of the stock, with a view to increasing the milk supply. Furthermore, the various small dairies are operated very inefficiently. Milking is done only once a day and it is custom to allow the calf to suckle first in order to start the flow. . . .

To this we may add that most of the dairies had no barns. The cows were kept in the pasture all day and were milked under thatched structures (ranchos) which had neither cement nor other solid flooring. Milking was frequently done by farm laborers who were paid for the extra service with a quart of milk daily. The cattle were fed only on grass. No method of cooling the milk was used and no special quarters were provided for storing either the milk or containers. Milk was carried in tin cans and peddled at every house door. Delivery was made by pouring from the can into any receptacle the purchaser might present. Refrigeration and the individual milk bottle were practically unknown. It is hardly necessary to say that milk produced under such conditions was a menace to health.

Although present conditions are not ideal, even the casual observer can see that a tremendous improvement has been made in the last ten years. Competition and improved economic conditions, together with a strenuous sanitary campaign, have operated to bring about changes in the industry of greatest benefit to the consumer.

At present wherever local organization permits proper enforcement, every dairy is required to have a stable constructed according to specifications of the Department of Health. Among other things, there must be ample ventilation, running water, concrete floors, milk room with cooler and bathroom for milkers. All milkmen must have certificates of good health issued by the Department of Health. Besides a routine physical examination, samples of blood are taken for the Wassermann test, of feces for intestinal parasites, nasopharyngeal exudate for diphtheria, and sputum for tuberculosis. All these examinations must be negative if the medical certificate is to be granted.

Most large dairies have refrigeration plants on the farms, but smaller dairies cannot afford such expense and use water coolers. Milk is brought to San Juan in large cans on motor trucks and cooled at the depots where it is bottled and distributed; or it is bottled at the dairy and sent directly to the consumer.

Pasteurization was not successfully practiced in Porto Rico up to last year (1927) when a plant was established in San Juan.* This is a modern plant with a capacity for 30,000 quarts. The continuous system is used. This pasteurized milk has been generally accepted by the public, and already another company is building a large plant.

Refrigeration is becoming more and more widely practiced, though in small towns development has been slow. The rapid spread of electric refrigeration is facilitating the change.

Competition and the wide educational campaign carried on for some years by the Department of Agriculture and Labor and the Department of Health have brought about a great change in methods, particularly as respects cleanliness, cooling of milk, sterilization of bottles, two daily milking periods, the use of concentrated feed, etc.

The average retail price of milk in San Juan is 20 cents a quart throughout the year. This price appears excessive, but if we study local conditions we shall see the reason for the high figure.

The native Porto Rican cow is a poor producer, averaging only 4 quarts a day. Dairy men began some years ago to import cattle from the United States—Holsteins, Guernseys, Jerseys and Ayrshires—but since the island was, and still is, tick infested, many of the imported cattle died from Texas fever. It was decided to import bulls, and cross the native cows with different breeds in order to improve the stock. Crossing has been going on now for several years and a new type of cow is being raised which is better adapted for dairying.

In Porto Rico the Department of Agriculture has started a campaign for tick eradication but the solution of that problem is un-

* Several plants were established previous to this but were commercial failures.

doubtedly a long way off. Imported cattle are quite expensive, as might be expected. Transportation alone from New York or Texas to Porto Rico amounts to some \$50.00 per head.

The price of grazing land too is very high in Porto Rico. Three-fourths of the most fertile land of the island is held by sugar interests either for growing cane or for pasturing draft animals, chiefly oxen. The continuous development of the sugar industry has driven the dairymen to small farms, where they are compelled to keep their cows in stables, with little land for grass.

Concentrated feed is used in practically all dairies. One pound is generally allowed for each quart of milk produced. All concentrated feed is imported from the United States, the average price for it here being 3 cents a pound. At the present time the best dairies have an average production of 9 or 10 quarts per head, while the poorer dairies get 4 to 6 quarts, averaging 7 to $7\frac{1}{2}$ quarts per cow. The average price paid to the dairyman for his milk is 12 cents a quart.

All these conditions—high cost of dairy cows, high cost and scarcity of land, and high cost of concentrated feed—together with low production, explain the high cost of milk.

The legal standard established by the Commissioner of Health is as follows:

All milk sold in Porto Rico must conform to the following standard:

Not less than 12 per cent dry residue

Not more than 88 per cent water

Not less than 3 per cent butter fat

Not less than 1.030 specific gravity

No foreign substance

Refraction not less than 36.5 at a temperature of 20° C. of the copper serum

Not less than 0.7 per cent mineral matter

No pathogenic bacteria

Not more than 500,000 bacteria per c.c.

As regards pasteurized milk, it is required that all raw milk coming to the plant for pasteurization shall not have more than 1,000,000 bacteria per c.c. and not more than 10,000 bacteria per c.c. after pasteurization. All pasteurized milk shall be sold within 36 hours after pasteurization. It shall be kept at 10° C. until it reaches the consumer, and shall be sold in original containers only.

The high price of milk increases greatly the temptation to adulterate, a temptation that is especially great in a country of low wages and much unemployment. Dilution with water used to be very common, but in recent years it has been markedly reduced by the enforcement of the statutes against the practice.

Another method which has come into vogue recently is the dilution

of raw milk containing high butter fat content with dried skim milk imported from the United States at a very low price. This adulteration is very hard to detect, especially when the content of the skim milk powder is less than 20 per cent.

Preservatives have been used at times in the attempt to make raw milk last longer. Bicarbonate of soda, boric acid or borate of soda seem to be the most used.

Routine bacterial counts on milk are being made and very few dairies fall below the standard. It is usually found that dairies where the cows are kept in the barns all day have higher counts than those in which the cows are brought in only at milking hours. There is an appreciable difference in counts between the cooler and hotter months. Refrigeration is often inadequate in the summer, even though here in the tropics there is a difference of only about 10° F. between the mean temperatures of summer and winter.

It is very hard to determine the per capita consumption of milk, especially in the rural zone where no accurate data are available. The average for the whole island has been estimated by the Department of Agriculture as only 30 gm. San Juan, the largest city in the island, consumes proportionally more milk than any other city in Porto Rico. Its per capita consumption is $\frac{1}{3}$ quart. No data of other cities are available, but it is the general opinion of health officers that it is considerably smaller. In determining the per capita consumption in Porto Rico the large amount of condensed, evaporated, and powdered milk which is imported should be included. Much butter and cheese are also brought in. It is difficult to secure either the amount of these supplementary dairy products, or to get any data as to their local distribution. But they do constitute very important additions to the general food supply.

Porto Rico has a high infant mortality, there being 147 deaths for every 1,000 births (average of the last 5 years). Diarrhea and enteritis head the list of causes of infant deaths. Milk has been blamed as the main cause of such a high infant mortality, but we believe this assertion is altogether unjustified, and that communicable diseases, ignorance, poverty, unsuitable and inadequate food, are responsible in large part for the high infant death rate.

The old statement that it was impossible to have pure, clean milk in the tropics on account of the high temperature has been proved wholly false. There is no reason milk in the tropics cannot be as good as in other climates, provided it is produced and handled by proper methods, and particularly if proper attention is given to refrigeration.

Diabetes in New York City

W. W. PETER, M. D., DR. P. H., FELLOW A. P. H. A.

American Public Health Association, New York, N. Y.

IN 29 years the diabetes death rate has doubled in New York City. During this period the death rates from many other diseases declined. The Department of Health records for the entire city, without distinction as to age or sex, show the average diabetes death rate per 100,000 people as follows:

1898.....	10.5
1898-1902.....	11.4
1903-1907.....	14.6
1908-1912.....	15.8
1913-1917.....	20.9
1918-1922.....	19.8
1923-1926.....	22.8

The death rates among males and females, all ages included, were:

TABLE I
DIABETES DEATH RATES PER 100,000

Years	Males	Females
1898.....	9.4	11.6
1898-1902.....	11.1	11.8
1903-1907.....	12.5	16.6
1908-1912.....	13.3	18.2
1913-1917.....	16.7	23.4
1918-1922.....	15.6	23.9
1923-1926.....	16.6	28.9

These general averages for 29 years, according to sex, indicate that the death rate increased in both sexes, but it increased more rapidly in females among whom the rate was consistently higher.

When did diabetes begin to take its toll of human life? Out of a total of 24,850 deaths from this cause in 29 years, only 126 deaths took place among children under 5 years of age.

Among boys and girls from 5 to 15 years of age, 422 deaths took place in this same period. In this age group, too, diabetes was not an important cause of death. Diabetes is clearly not to be classed among the diseases of childhood, as are diphtheria, measles and whooping cough.

In the high school and college group, that is, from 15 to 24 years of age, a total of 680 deaths occurred in this 29-year period. This represents a slight increase, it is true, but even at this age period diabetes was not a very important factor.

In the upper age groups diabetes worked its greatest havoc.

TABLE II
DIABETES DEATHS BY AGES

	25-44 Years	45-64 Years	65 Years and Over
5 years, 1898-1902.....	343	914	605
5 years, 1903-1907.....	432	1,422	933
5 years, 1908-1912.....	481	1,969	1,094
5 years, 1913-1917.....	619	2,786	1,531
5 years, 1918-1922.....	676	2,831	1,754
4 years, 1923-1926.....	403	2,886	1,875
Total.....	2,954	12,808	7,792
Grand Total.....			23,554

Some one may point out that the above three columns do not tell the whole story; that the important factor of growth of population was not included. "If New York City maintained only a stationary population, the above figures would be alarming. But remember how the city has grown. It may have grown so fast during these 29 years that 914 deaths those first 5 years may mean a rate actually higher than 2,886 deaths the last 4 years." Further classification of the death rates per 100,000 population, as shown in Table III, indicates such changes as took place.

TABLE III
DIABETES DEATH RATE PER 100,000 POPULATION IN THE 25-44 YEAR AGE GROUP

Years	Death Rate	Years	Death Rate
1898-1902.....	5.0	1913-1917.....	6.9
1903-1907.....	5.8	1918-1922.....	6.9
1908-1912.....	6.1	1923-1926.....	4.9

DIABETES DEATH RATES PER 100,000 POPULATION AMONG MALES AND FEMALES IN THE 45-64 YEAR AGE GROUP

Years	Males	Females	Average
1898-1902.....	37.1	43.8	40.4
1903-1907.....	45.8	59.6	47.7
1908-1912.....	50.6	70.5	60.6
1913-1917.....	55.9	85.4	70.6
1918-1922.....	46.1	79.2	64.7
1923-1926.....	53.1	101.7	77.4

DIABETES DEATH RATES PER 100,000 POPULATION AMONG MALES AND FEMALES AGED 65 YEARS AND OVER

Years	Males	Females	Average
1898-1902.....	116.5	130.9	123.7
1903-1907.....	138.6	186.1	162.3
1908-1912.....	153.0	184.9	168.9
1913-1917.....	172.4	225.5	198.9
1918-1922.....	157.3	230.2	193.7
1923-1926.....	197.3	303.8	250.5

CONCLUSION

This study of the diabetes incidence in New York City for a period of 29 years—1898 to 1926—supports the view that diabetes is a dis-

ease of adult life. It causes death most frequently just at that period when people are most productive in an economic sense. In the 29 years under review, only 1,296 deaths occurred among those under 25 years of age. Out of a total of 24,850 deaths, 23,554 took place among those who had passed their 25th birthdays. Of the 23,554 deaths, more than half occurred in the 45-64 year age group.

NOTE: Acknowledgment is due Louis I. Harris, M.D., formerly Commissioner of Health of New York City, for providing the statistical material and other assistance for this study.

The Texas Job

W. J. V. DEACON, M. D., FELLOW A. P. H. A.

State Department of Health, Lansing, Mich.

TEXAS is the largest state in the union not now in the U. S. Registration Area for either births or deaths. Not only is it the largest in area but its population is about $5\frac{1}{2}$ millions.

In addition to the official agencies, the American Public Health Association has been extending every effort to aid the U. S. Bureau of the Census in the completion of the registration area and has a special committee for that purpose, and because of the fact that Texas is such an important state the interest of the Association and its committee has been very keen. Arrangements were made to send the writer to Texas at the expense of the Association Committee to Aid Completion of the Registration Area by 1930, so he might aid the state in preparing for the registration area.

The Texas Legislature of 1927 passed a new vital statistics law which is similar to the Model Law, and this law became effective September 1, 1927. About that time W. H. Lackey, Special Agent of the Bureau of the Census, was sent to Texas to aid in the organization but he naturally could only be of advisory assistance. Later the U. S. Children's Bureau had 3 representatives in the field. April 1, W. A. Davis, M.D., was appointed Director of the Bureau of Vital Statistics.

There are 254 counties in Texas and the law provided for a local registrar in each justice precinct and each incorporated place. There are from 4 to 8 justice precincts in each county, although 2 or more precincts could be combined for efficiency of registration. It was found that only 67 of these counties had been organized by the appointment of local registrars and no campaign for registration could be begun until there was a place for the registration of births and deaths. The necessity for completing the organization of the state was apparent.

The appropriation for all health work in Texas was pitifully inadequate and it was necessary to ask for further aid on the outside. After a good deal of correspondence, Louis I. Dublin, Ph.D., the chairman of the committee, succeeded in securing the services of 4 additional men from the Bureau of the Census, the expenses, however, being borne by the committee. The National Tuberculosis Association through its statistician, Jessamine Whitney, furnished additional help in the person of Alice M. Hill. The territory was divided in the best possible manner to facilitate travel—and the campaign was on.

The justice precincts in many cases are indefinitely outlined. In many cases not a single county official could tell definitely where the lines belonged. To go into these districts and locate a proper individual to serve as registrar was a tremendous task. Many registrars were appointed who are undoubtedly not suited to the work, and changes will be necessary, but by June 1 the organization of the state was completed, with a registrar appointed for every precinct or combined district and a definite place for the filing of all birth and death certificates.

There were at the time 11 persons from outside the state at work, all on organization work, with the exception of I. R. Whipper, M.D., a negro woman physician who was put on promotion work among negro midwives. Those engaged in the work were as follows:

American Public Health Association: W. J. V. Deacon, M.D., and Carolyn J. Loewenstein, stenographer

U. S. Children's Bureau: Marie T. Phelan, Alice E. Griffith, and I. R. Whipper

National Tuberculosis Association: Alice M. Hill

U. S. Bureau of the Census: W. H. Lackey, C. C. Jermain, J. J. Hughes, J. C. Stafford, and E. C. Walker

Upon the completion of the organization, the extra Census men were released and the energies of all of those remaining in the field were turned to the promotion work. It was felt that but little could be accomplished in the attempt to do intensive rural work and that our only hope of success lay in bringing the counties in which there were big cities up to the point where registration was reasonably complete. There were about 40,000 unreported births in Texas in 1927. In one county alone in which one of the large cities is located were practically 4,000 of these. If it were possible to bring this county up to complete registration we would account for approximately 10 per cent of our total deficiency.

Every effort was made to use all of the existing agencies in the state such as the chambers of commerce, the American Legion, the parent-teacher associations, the state and county medical societies and their auxiliaries, all of the luncheon clubs, etc.

The writer closed this tour of duty on August 1 and at that time all of the outside workers were withdrawn with the exception of 3 representatives of the U. S. Bureau of the Census who were to aid in vital statistics until about August 15 when they would be assigned to other Census duties but would be permitted to do such work in vital statistics as they could in connection with their other work.

J. C. Anderson, M.D., State Health Officer, and W. A. Davis, M.D., director of the bureau, have been keenly interested and have helped as far as possible within their means. Dr. Davis has of course a tremendous job to organize his office to a state of efficiency, particularly as he has no trained help due to political turn-over in the past, but his organization is gradually being assembled and when trained should furnish the state an efficient registration unit.

The job was a difficult one but we are in hopes that some good will develop from our efforts.

OUR 57TH ANNUAL MEETING

THE 57th Annual Meeting will go down in history as one of the best and largest. It was held in conjunction with the American Child Health Association, at the same time as meetings of a number of related societies, such as the American Association of School Physicians, American Social Hygiene Association, International Association of Dairy and Milk Inspectors, Association of Women in Public Health, Conference of State Sanitary Engineers, State Laboratory Directors Association, Women's Foundation for Health and the Conference of Illinois Health Officers and Public Health Nurses. All of the sessions were held in the Stevens Hotel, which was the headquarters of the Association.

The result was an unusually large concourse of public health workers along various lines.

The General Sessions, held in the evenings, were all broadcast, and every afternoon eminent workers in the field of public health contributed to the radio program. There were on the scientific programs 280 speakers and 80 scheduled functions, in addition to informal group meetings. The Health Exhibit was unusually complete and large, with 102 exhibitors. The hall was open to the public during the late afternoons and evenings. This exhibit was so successful that it is our intention to continue it as a permanent feature.

The Scientific Exhibit was also unusually extensive and well organized, and, judging from the large attendance, it served the purpose intended by its directors. Here health officers could see what other communities are and have been doing, since a number of cities and states had exhibits which were prepared with the utmost care, giving graphic presentation of the problems which confront every health officer.

In addition to the exhibits at the place of meeting, there were

traveling exhibits in the Illinois Central Railroad yards where the latest models of glass-lined tanks for the shipment of bulk milk were shown; the Missouri Pacific Better Health Car and the Mine Rescue Car sent out by the U. S. Bureau of Mines were exhibited and explained to visitors by trained workers. Motorized laboratories for the examination of water and other interesting aids employed by state health departments were parked within a short distance of headquarters.

Last year for the first time the problem of undulant fever was brought to our attention. This year it was one of the most important features of the entire program, having been considered in the Laboratory Section in a symposium. There seems to be no question that undulant fever is much more widely distributed than has been suspected. While its incidence will vary according to the part of the country considered, everywhere it is one of the newer problems with which the health officer must cope. One rather startling feature brought out in the discussion of undulant fever was an unsuspected prevalence of typhus fever in the southern part of the country.

Needless to say, the discussion on foods and nutrition received due attention. Two subjects which are comparatively new to our meetings were featured: one, the influence of the lack of sunshine, due to pollution of the air; and the other, oral hygiene, which was considered at a special joint session.

It is impossible and would be invidious to pick out certain papers for special attention. On the whole the papers presented were high class and most of them considered practical problems. Despite what we have just said, we wish to call attention to the address of Dr. Frank G. Boudreau, of the Health Section of the League of Nations, explaining the functions and working of the Health Section of the League of Nations, in which he stated his conviction that the public, including even physicians and health workers, is too little aware of what is being done by this body and of its importance to world health.

We were especially glad to note an unusually large number of delegates from the southern republics, Mexico and Cuba, which are constituent members of the Association. Canada was well represented, and we were glad to see two of the pillars of the Association, who are known to young and old members alike, Drs. Charles H. Hastings of Toronto, and Peter H. Bryce of Ottawa.

To the Local Committee, headed by Louis E. Schmidt, M.D., the Association owes a debt of gratitude, not only for the excellent arrangements made for the meeting, but also for its untiring and constant watchfulness during the session.

While the unexpectedly large attendance proved too much for the capacity of the rooms of certain sections during some of the discussions, we must feel great satisfaction over the intense interest shown by such a large number of people. The total registration was about 2,800. The new president of the Association is George W. Fuller, of New York City. Our 58th Annual Meeting in 1929 will be held in Minneapolis, Minn.

The Chicago meeting will stand out always as an unusual success and all who were fortunate enough to attend will bear in grateful remembrance the many courtesies of which they were the recipients.

OPPORTUNITIES MISSED BY PHYSICIANS

ALTHOUGH we can find statements proving that physicians for many centuries have had some ideas of the prevention of disease, we still believe it to be the fact that they have been more concerned in the healing of the sick than in the causes and conditions leading to disease. We know that Sir Edwin Chadwick began the hygienic reform in England, while Lemuel Shattuck took the lead in the United States. Pasteur, who was not a physician, revolutionized medicine, so that our debt to non-medical men is great, and can be satisfied only by accepting their findings and promulgating their ideas.

The recent studies of nutrition have brought to the front the name of another man, Captain James Cook, who, without any training in medicine, worked out for himself the prevention and even cure of a disease which was formerly the scourge of sailors; namely, scurvy. He was the son of a farm laborer, born in 1728, in Yorkshire, England. He began his career on the sea as a boy on coal vessels, in which he spent 12 years of his life. He finally joined the Royal Navy as an able seaman, and soon after made the acquaintance of scurvy. The first ship on which he served, after a cruise lasting only between three and four months, returned to port with 130 men sick, of a crew of 400. Two years later he was promoted to master, and served on the North American Station where scurvy was only too frequently seen. Later he was put in command of the "Endeavour" which was sent to the South Sea Islands in 1769. At the end of five months, his surgeon reported that there was no scurvy on the ship. He spent six months surveying and charting the coasts of the islands in the neighborhood of New Zealand, and later the east coast of Australia. After having been partially wrecked on a reef, he made temporary repairs, and

finally reached Batavia, from which point he sent a report to the Admiralty saying that during the entire voyage he had not lost a single man from scurvy. Unfortunately there was a great deal of sickness at Batavia, and before he reached the Cape of Good Hope 34 deaths had occurred from fever and dysentery.

Two of his observations stand out with especial clearness. He carried, as antiscorbutics, malt, sauerkraut, orange and lemon juices, soup, and always obtained vegetables when possible. At Tierra del Fuego, he collected wild celery, and one meal a day consisted of this with ground wheat and soup. He also used all the wild herbs he could obtain. It is interesting to note that he had difficulty in making his seamen eat some of the new messes which he prepared, but he had them on his own table for himself and officers, and when the men saw this, they ate them. Captain Cook says of them that they were of "infinite service" in preventing the "scorbutic taint."

The second observation made by Cook was that even the best articles of food sometimes failed unless supplemented by other hygienic measures. He changed the old watch hours, four on and four off, so that the men had eight hours off duty twice in 24 hours. In addition, he fumigated the ship, keeping her as clean and dry between decks as possible, and insisted that too much attention could not be paid to ventilation and keeping the air pure.

On his second voyage, which lasted three years and eighteen days, Cook was in charge of two ships selected by himself. During that time, he did not lose a single man from scurvy on his own ship, "Resolution," though several on the "Adventure" died from the disease, unquestionably because he was not on board and his orders were not strictly carried out. For his discovery and the good results obtained from it, he was unanimously elected a Fellow of the Royal Society, and was soon after awarded the Copley medal.

On his third voyage he was killed in a fight at Hawaii, but his officers had learned their lesson, and though both ships were cruising four years and two months, not a single case of scurvy occurred on either one.

Cook's observations seem to have been made without the assistance of physicians and without any particular medical knowledge. His name will always be honored as the man who banished from the seas a dreaded and crippling disease which had for many years taken its toll of the "toilers of the sea."

SEWAGE WORKS JOURNAL

ON October 1, the *Sewage Works Journal* made its first appearance. This fine magazine is the official publication of the Federation of Sewage Works Associations, the purposes of which are described in its constitution as being:

The advancement of fundamental and practical knowledge concerning the nature, collection, treatment and disposal of sewage and industrial wastes, and the design, construction, operation and management of sewage works, through the correlation and strengthening of local, state and district sewage works associations, and the publication of a journal designed to meet the needs of persons active or interested in these fields of endeavor.

The promotion and encouragement of improved waterways sanitation, through the same measures.

The material in the first issue of the new journal will be of great interest to engineers in the public health field and of more limited interest to all sanitarians.

Many of the members of the Federation's working committees are members of the American Public Health Association and the Association is therefore much gratified in observing the success with which the efforts of the first group of persons interested in this movement have been rewarded. One of the meetings of the group which fostered the organization of the Federation was held conjointly with the meeting of the Association last year.

We wish the Federation success in this effort, as well as in all its work.

ASSOCIATION NEWS

The new officers of the Association for 1928-29 are as follows:

President, George W. Fuller

First vice-president, A. J. Chesley, M.D.

Second vice-president, Norman MacL. Harris, M.B.

Third vice-president, Louis E. Schmidt, M.D.

Treasurer, Edwin O. Jordan, Ph.D.

The newly elected members to the Executive Board are:

Hugh S. Cumming, M.D.

Haven Emerson, M.D.

William C. Hassler, M.D.

The newly elected Governing Councilors for the term expiring in 1931 are:

Hugh S. Cumming, M.D.

Lee K. Frankel, Ph.D.

E. V. McCollum, Ph.D.

A. T. McCormack, M.D.

J. W. S. McCullough, M.D.

Stanley H. Osborn, M.D.

W. S. Rankin, M.D.

M. P. Ravenel, M.D.

W. F. Snow, M.D.

H. A. Whittaker, C.E.

The Fifty-eighth Annual Meeting will be held in Minneapolis, Minn.

GEORGE W. FULLER, PRESIDENT
A. P. H. A.

MR. FULLER was born December 21, 1868, at Franklin, Mass., and was graduated from the Massachusetts Institute of Technology in 1890. He took the courses in bacteriology at the Hygienic Institute at the University of Berlin and later studied in the private office of Piefke, Engineer of the Berlin Water Works.

About nine years were then devoted to research work on methods of purifying water and sewage from the biological, chemical and engineering viewpoints. He was with the Massachusetts State Board of Health for nearly five years, first as a bacteriological assistant to Prof. Sedgwick during investigations of typhoid epidemics in the Merrimac Valley, and later was in charge of the Lawrence Experiment Station. In 1895 he went to Louisville and there and at Cincinnati had charge for nearly four years of extensive investigations of the means of purifying Ohio River water.

Mr. Fuller has been in private practice since 1899 with offices in New York, specializing in matters of water supply, water purification, sewerage and sewage disposal. He was in partnership with

the late Dr. Rudolph Hering from 1901 to 1911. He has also devoted much study to economic problems, especially as related to the valuation of water works and street railway properties in the Pittsburgh, Philadelphia and Buffalo districts. For several years he was expert adviser to Mitten Management, Inc.

GEORGE W. FULLER

Mr. Fuller has taken a keen interest in activities aimed toward standardization of practices related to the public health field. He was secretary of the convention of bacteriologists, held in New York in June, 1895, to consider improved methods and was a member of the committee reporting on this subject in 1896-97. In 1899 at the Minneapolis meeting of the American Public Health Association he was appointed chairman of the first Committee on Standard Methods of Water Analysis. It presented its report at the meeting of the Association at Havana in January, 1905.

He was chairman of the Standardization Council of the American Water Works Association from 1920 to 1927 and was active in preparation of the *Manual of Water Works Practice* appearing in 1925.

Mr. Fuller has served the American Public Health Association in many capacities—as chairman of the Committee on Organization in 1925; member of the Governing Council from 1923; member of the Executive Board 1924-1928, serving two terms; member of the Finance Committee 1927-1928; and first vice-president of the Association 1927-1928.

He has served more than 150 of the larger cities and towns in various parts of the United States and Canada in matters of water supply, sewage disposal and control of stream pollution.

For over 20 years he has been active on developments related to the problems of the Sanitary District of Chicago and was on a commission in 1921-22 which selected the method and locations of the project now known as the North Side Sewage Treatment Works.

Mr. Fuller was a member of the Franco-American Engineering Congress convened at Paris directly after the Armistice to consider various reconstruction and economic problems in France.

He is a Past President of the American Water Works Association, Vice-President of the American Society of Civil Engineers, member of the American Chemical Society and American Society of Bacteriologists; Institution of Civil Engineers of Great Britain, and the Engineering Institute of Canada. He is a member of the Committee on War Memorial to American Engineers at Louvain, Belgium, representing the American Society of Civil Engineers. He is a member of the Executive Committee and Chairman of the Committee on Promotion and Attendance of the World Engineering Congress to be held at Tokyo, Japan, November, 1929.

Mr. Fuller has written three books, including: *Water Purification at Louisville*, 1898; *Sewage Disposal*, 1912; and in association with J. R. McClintock, his partner, *Solving Sewage Problems*, 1926.

RESOLUTIONS

Presented by the Committee on Resolutions, W. S. Rankin, M.D., Chairman, and adopted by the American Public Health Association at the Fifty-seventh Annual Meeting, Chicago, Ill., October 15-19, 1928.

ASSISTANCE TO FLOOD AREA

1. WHEREAS, during the unprecedented floods in the Mississippi Valley in 1927, for the first time in American history, an effective public health program was initiated in more than 90 counties in the 7

states involved in that disaster, which involved the setting up in them of full-time health departments, with adequately trained personnel; which resulted in the saving of many lives and much unnecessary illness; and

WHEREAS, this program was inaugurated by the Surgeon General of the U. S. Public Health Service, the Medical Director of the Rockefeller Foundation, and the Governors and Health Officers of the states involved, and made possible by the generous approval of the President and the Congress; and

WHEREAS, it was contemplated that this coöperation program might be terminated in 18 months; but that this hope was dissipated by a repetition in 1928 of floods in the same area quite as economically disastrous as those of the preceding year; now, therefore, be it

RESOLVED by the American Public Health Association in its annual convention assembled, that it approves the wise plan of public health administration successfully operated in the Mississippi Valley for the past 18 months, and, being advised as to the economic condition in these counties, and further realizing that adopted federal plans will soon start public work in these counties involving much larger groups of labor than were found necessary to build the Panama Canal, with resulting public health problems quite as great as that monumental enterprise, that it memorializes the President and the Congress to continue the assistance that is being extended to these counties for 2 more years, after which it should be gradually reduced over a term of several years until each of the counties affected is restored to economic independence.

PARKER BILL

2. WHEREAS, the Parker Bill for the correlation of federal health activities was passed by the Congress of the United States at the first

session of the Seventieth Congress, but was vetoed by the President on May 18, 1928; and

WHEREAS, the principles of this excellent and necessary measure have been endorsed each year for the past 3 years by the American Public Health Association in convention assembled; therefore, be it

RESOLVED, that the American Public Health Association most strongly urges that Congress pass the Parker Bill for federal health co-ordination over the veto of the President, in order that the country may have the benefit of this advantageous legislation.

TUBERCULOSIS

3. RESOLVED:

1. That, in the light of our present knowledge of tuberculosis, every case should be placed under appropriate sanitary control;

2. That the essential part of any effort in bringing tuberculosis cases under control depends primarily upon the existence of an accurate and complete registration of cases;

3. That state and local health officers should take the initiative in promoting the reporting of cases by physicians and institutions;

4. That local health officers be requested to secure more complete and accurate reporting in their respective districts;

5. That the success of reporting tuberculosis depends upon the sympathetic support of the medical profession;

6. That the subject of the reporting of tuberculosis cases be presented to state and local medical societies, asking for their co-operation and support.

IN MEMORIAM

4. RESOLVED, that it is with a sense of irreparable loss that the American

Public Health Association takes note of the deaths since our last meeting of the following members and Fellows:

T. Howard Barnes,
New York, N. Y.

Clarence W. Bassett, M.D.,
Sharon, Conn.

Arthur W. Bingham, M.D.,
New York, N. Y.

Arthur G. Bretz, M.D.,
New York, N. Y.

Chauncey F. Chapman, M.D.,
Lincoln, Neb.

Daniel Connolly, M.D.,
Kingston, N. Y.

Prof. Charles I. Corp,
Madison, Wis.

H. A. Duemling, M.D.,
Ft. Wayne, Ind.

C. E. Durham, M.D.,
Austin, Tex.

Joseph C. Elfers, M.D.,
Sheboygan, Wis.

L. M. Field, M.D.,
Beloit, Wis.

Matthew J. Fitzpatrick, M.D.,
Mason City, Ia.

Perry D. Gaunt, M.D.,
Warsaw, Ill.

Winifred S. Gibbs,
New York, N. Y.

Col. V. Havard,
Fairfield, Conn.

Edward A. Holmes, M.D.,
Downsville, N. Y.

Walter B. James, M.D.,
New York, N. Y.

Prof. James O. Jordan,
Boston, Mass.

Francis M. Kennedy, D.D.S.,
New Bedford, Mass.

F. H. Lee, M.D.,
Canaan, Conn.

Harriet L. Leete, R.N.,
Far Rockaway, N. Y.

Adam S. MacKnight, M.D.,
Attleboro, Mass.

R. C. Mahaney, M.D.,
Owosso, Mich.

Charles E. Marshall,
Amherst, Mass.

John D. McCarthy, M.D.,
New York, N. Y.

William Morris,
Roselle, N. J.

Francis M. Munson, M.D.,
LaPlata, Md.

W. E. Musgrave, M.D.,
San Francisco, Calif.

Joseph Y. Porter, M.D.,
Key West, Fla.

Mrs. S. R. Prentiss,
Bangor, Me.

S. H. Rantz, M.D.,
Placerville, Calif.

Tom Rosenfield,
Rock Island, Ill.

Frank C. Smith,
Auburn, N. Y.

John A. Smith, M.D.,
Jackson Heights, N. Y.

Francis R. Smyth, M.D.,
Bismarck, N. D.

J. Ross Snyder, M.D.,
Birmingham, Ala.

Margaret Tupper, R.N.,
Paris, France

Solomon Weingrad, M.D.,
Mountaindale, N. Y.

S. W. Welch, M.D.,
Montgomery, Ala.

R. A. Wilson, M.D.,
El Paso, Tex.

YELLOW FEVER HEROES

5. WHEREAS, an unsuccessful effort at the last session of Congress was made to obtain federal legislation

in the interest of the yellow fever heroes in 1900 and their survivors, and

WHEREAS, this Association is informed that a new bill, revised to meet some of the objections to the bill which was defeated in the last session of Congress, will be introduced in the next Session of Congress; now, therefore, be it

RESOLVED, that it is the sense of the American Public Health Association that the people of the United States are under a great and lasting obligation to the soldiers and officers of our country who, in an heroic way, laid the sure foundation for the ultimate and complete control of that great tropical and semitropical scourge, yellow fever; and be it further

RESOLVED, that the Association gives its unqualified endorsement to the proposed legislation and expresses its earnest desire that the next session of Congress give favorable consideration to the new bill and so signalize the lasting gratitude of our people for those who suffered and died for the honor and advancement of our country.

POSTAL LAWS

6. WHEREAS, the promotion of public health depends largely on the systematic instruction of the public in health matters, and

WHEREAS, experience has shown that such instruction is greatly facilitated by the regular publication of bulletins of information by health authorities, and

WHEREAS, in the distribution of such bulletins by mail, the U. S. Postal Laws and Regulations now grant the "second class mailing privilege" to state boards of health but not to county or municipal boards of health, and

WHEREAS, this discrimination un-

justly imposes a heavy financial burden on county or municipal boards of health, and greatly restricts their educational activities, be it

RESOLVED, that the American Public Health Association protests against this unjust discrimination and respectfully requests that Congress amend Section 395 of the Postal Laws, Act of August 24, 1912, by adding the words "county and municipal" so that the second class mailing privilege shall hereafter be extended to "the bulletins issued by state, county, and municipal boards of health"; and be it further

RESOLVED, that a copy of this resolution be forwarded to the Postmaster General and to members of the committees on postal affairs in both houses of Congress, and that the members of this Association be requested to call this resolution to the attention of their representatives in Congress and urge adoption of the amendment therein requested.

CRESSY L. WILBUR

7. WHEREAS, by the recent death of Dr. Cressy L. Wilbur, for years one of the foremost active members of the American Public Health Association, and one of the organizers of the Section on Vital Statistics, an outstanding figure in public health work has left the state of human endeavor, be it

RESOLVED, that the American Public Health Association record its very great indebtedness to its beloved colleague and enter on the minutes of this meeting the following brief biographical note:

Cressy Livingston Wilbur was born at Hillsdale, Mich., March 16, 1865. Graduating from Hillsdale College in 1886, he was the recipient of a Masters

Degree in Philosophy four years later. In March, 1890, Bellevue Hospital Medical College conferred upon him the degree of Doctor of Medicine.

Dr. Wilbur entered into public health work as Chief of the Division of Vital Statistics of the State of Michigan in 1893, serving as such for thirteen years, during which period he found time to lecture on vital statistics in the Medical Department of the University of Michigan, and to act as Expert Special Agent of the U. S. Bureau of the Census, in charge of expansion of the U. S. Registration Area.

Appointed as Chief of the U. S. Bureau of Vital Statistics, July 1, 1906, his field of work assumed a national and international scope. He was the official delegate of the United States to the International Congress for the Revision of the Classification on Mortality and Morbidity, held at Paris, July, 1909. To Dr. Wilbur the credit is due for the preparation of the Model Registration Law, and it was because of his constant efforts that twenty states enacted laws providing for the adoption of this law. He was tireless in working for the extension of the registration area. In 1906, the percentage of the population in the registration area was 49 and in 1914, when his services as Chief Statistician of the U. S. Bureau of the Census ended, the percentage was 66. Cali-

fornia, Colorado, Maryland, Pennsylvania and South Dakota were added in 1906; Washington and Wisconsin in 1908; Ohio in 1909; Minnesota, Montana, North Carolina and Utah in 1910; Kentucky and Missouri in 1911; Virginia in 1913; Kansas in 1914.

He was the chief mover in the re-creation of the section on Vital Statistics of the American Public Health Association, carrying his efforts to a successful conclusion at the meeting of this Association in 1907. For years thereafter his great interest lay in building up the section, and he never ceased to urge its members to spread the gospel of complete registration of sickness and death, and the adoption of standard tables of mortality and morbidity.

In 1914, the late Hermann M. Biggs, M.D., invited Dr. Wilbur to accept the post of Director of the Bureau of Vital Statistics of the New York State Department of Health, a position in which Dr. Wilbur served for several years with distinction, his efforts being concentrated on obtaining a complete registration of births and deaths in the Empire State.

Those who had the good fortune to be associated with him knew Dr. Wilbur as a modest, kindhearted, lovable colleague, and as one who adhered steadfastly to the principles of honest, fair dealing with all.

DR. DE KLEINE GOES TO RED CROSS

William De Kleine, M.D., director of the Child Health Demonstration conducted by the Commonwealth Fund at Salem, Ore., has resigned to become medical assistant to James L. Fieser, vice-chairman in charge of domestic op-

erations of the American Red Cross. Dr. De Kleine assumed his duties at national headquarters in Washington, D. C., November 1. He will succeed Dr. William R. Redden, who recently resigned. Dr. De Kleine is a Fellow of the A. P. H. A.

NEW MEMBERS

- Roy Bennett Adams, Lincoln, Neb., School Physician
- Alma Arneson, Chicago, Ill., Tuberculosis Worker, Sedgwick Street Dispensary
- Henry L. Banzhaf, B.Sc., D.D.S., Milwaukee, Wis., Dean, Dental School, Marquette University
- Mary L. Beal, Fargo, N. D., Supervisor of Health Education
- Mrs. D. Pirie Beyca, Des Moines, Ia., Lecturer for State Board of Health
- Maurice A. Bigelow, Ph.D., New York, N. Y., Director, School of Practical Arts, Teachers College, Columbia University
- George E. Carrothers, Ann Arbor, Mich., Teacher of School Administration, School of Education, University of Michigan
- George Collins, Raleigh, N. C., Director, Bureau of Maternity and Infancy, State Board of Health
- Edward M. Dodd, M.D., New York, N. Y., Medical Secretary, Presbyterian Board of Foreign Missions
- Mark H. Fox, Jacksonville, Fla., President, Seminole Milk Company and Dublin Creamery Company
- Harry H. Freilich, M.D., Chicago, Ill., Tuberculosis Worker, Robey Street Dispensary
- J. F. Fulton, M.D., Staunton, Va., Health Officer
- William Henry Gaub, Cambridge, Mass., Student, University of Michigan (Assoc.)
- Albert S. Gray, M.D., Hartford, Conn., Chief, Division of Occupational Diseases, State Department of Health
- P. W. Gumaer, A.B., B.S., New York, N. Y., Consulting Engineer, The Barrett Company
- Freda M. Gustafson, Chicago, Ill., Tuberculosis Worker, Robey Street Dispensary
- Kirby A. Henkes, Springfield, Ill., Junior Bacteriologist, Diagnostic Laboratory, State Department of Public Health
- Clifford R. Hervey, M.D., Oswego, N. Y., District State Health Officer
- Marion O. Lerrigo, Ph.D., New York, N. Y., Research Worker in Health Education, Emma Dolfinger Memorial Fund
- John N. Libert, M.D., St. Cloud, Minn., Health Officer
- Lenna L. Meanes, M.D., New York, N. Y., Medical Director, Women's Foundation for Health
- Mrs. George D. Morgan, Galveston, Tex., Chairman, Red Cross Public Health Nursing Service (Assoc.)
- Edward M. Morgenstern, M.D., Chicago, Ill. (Assoc.)
- Alexandre Moscoso, M.D., Rio de Janeiro, Brazil, Public Health Officer, National Department of Health (Assoc.)
- L. R. Murphree, M.D., Athens, Ala., Health Officer, Limestone County
- Helen M. Needles, R.N., Des Moines, Ia., Lecturer for State Department of Health
- Annie M. O'Donnell, Sc.D., Greensboro, N. C., Head, Division of Hygiene, North Carolina College for Women
- Russell H. Paden, M.D., Charleston, W. Va., Director, Division of Child Hygiene, State Department of Health
- Walter A. Peirce, Racine, Wis., Manager, Water Department
- Mrs. A. R. Peterson, New York, N. Y., Promoter of Public Health Activities (Assoc.)
- Frederick Peterson, M.D., New York, N. Y., Promoter Public Health Activities (Assoc.)
- C. W. Pfeiffer, M.A., St. Paul, Minn., Executive Secretary, Community Chest (Assoc.)
- Aurelia B. Potts, R.N., Ann Arbor, Mich., Student (Assoc.)
- Bernard E. Proctor, Ph.D., Cambridge, Mass., Instructor, Department of Biology and Public Health, Massachusetts Institute of Technology
- Mrs. Daisy G. Rice, Alton, Ill., Inspector of Hygiene, Public Schools
- Harry W. Rosenthal, Dr.P.H., M.D., Baltimore, Md., Mental Hygienist, University of Maryland

- Charles Alfred Lee Reed, M.D., formerly President of the A. M. A. Elected member 1924.

A TRIBUTE TO SAMUEL WALLACE WELCH

SINCE the death on August 22, 1928, of Samuel Wallace Welch Alabama's beloved health officer, expressions of sorrow and loss have come from throughout Alabama and the United States.

Before the impress of this great personality shall have become dimmed by time, a record and an appraisal of his life should be made by those who are best qualified to interpret it for the benefit of future generations.

What manner of man was he and what did he do?

The record of his official acts may be sparsely gleaned from original sources: He was called from a small country practice in Talladega, Ala., to the state health office in Montgomery in 1917 at a time when leadership in the health field was needed more than at any other. This period marked the entrance of the United States into the World War. Three great army camps were located in Alabama. Dr. Welch immediately manifested the remarkable vision which characterized his entire public health career.

The U. S. Public Health Service was called into consultation and induced to initiate a program of disease prevention in all federal reservations.

From this time forward the record of a decade shows steady advancement along all lines: Increased appropriations, additional voluntary subsidies from outside sources; enunciation of sound policies of organization and administration; successful defeat of destructive legislation; successful promotion of legislative measures necessary to health protection; wise decisions with regard to work to be undertaken and selection of staff members; the winning of friends for the health department and the confidence of worth while people in his ability as a leader; the winning of recognition for Alabama's health pro-

gram not only among her own people but among the leaders of public health thought in the United States; the cordial reception of visitors from other states and countries and the effective presentation of his programs and convictions with regard to these programs.

His was indeed a valiant spirit which could not brook defeat. His career went seemingly from peak to peak of success gained and honors won; the vales of struggle and trial were never magnified.

The deep motivating influences which shaped his life were a profound urge to bring more of health and joy to the people of his state and eventually to the world.

His every effort was directed by sound knowledge and fashioned or administered in common sense and kindness.

No labor was too heavy, no sacrifice too great, no hour too late or too long if it were needful to the completion of a necessary task.

But more than all of these must count, in the final reckoning, the fact that Dr. Welch was possessed of the power to inspire a personal love in the hearts of men coupled with a sense of devotion to the causes espoused by him.

And I say that life is indeed darkness save where there is urge;
And all urge is blind save where there is knowledge;
And all knowledge is vain save where there is work;
And all work is empty save where there is love;
And when you work with love you bind yourself to yourself,
And to one another and to God.

Anything like an adequate appraisal of the contribution to human welfare made by the life of Samuel Wallace Welch must await the commitment to this task of an inspired pen.

DOUGLAS L. CANNON,
*Acting State Health Officer,
Montgomery, Ala.*

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Diphtheria Prevention in France

—An antigen entirely different from the toxin-antitoxin mixtures was proposed in France in 1923 for active immunization against diphtheria. Diphtheria anatoxin was developed and later perfected by the phenomenon of flocculation. Diphtheric toxin is converted into anatoxin by means of the combined action of formaldehyde and prolonged heat. To be called anatoxin, however, it must have an intrinsic antigen value, and must also be inoffensive toward sensitive animals.

Anatoxin does not render the subject sensitive to injections of horse serum since it does not contain a protein substance of such origin. The usual initial dose is 0.5 c.c. given subcutaneously, and 3 weeks later 1 c.c. is injected. In many instances it is unnecessary to give a third injection of anatoxin, but where required the interval between the second and third injection is about 15 days and the dosage is 1 to 1.5 c.c. During the past four years diphtheria vaccination by means of anatoxin has been performed on persons of various ages and it is estimated that a million injections have been made with no serious or fatal accident. Reactions have been mild, there being a slight reaction in from 20 to 40 per cent of cases and a strong reaction occurring in only 1 to 5 per cent of the cases. The occasional reactions are far less severe than those following other vaccinations such as vaccination against smallpox or antityphoid vaccination.

The authors cite many individual experiences in the use of anatoxin for active immunization. They conclude that two injections of anatoxin immunize

from 90 to 95 per cent of patients, and three injections from 97 to 100 per cent. Sufficient protection develops in from 5 weeks to 2 months to give a negative Schick test in those who were positive before vaccination.—G. Ramon and G. I. Helie, *Diphtheria Prophylaxis in France*, *J. A. M. A.*, 91: 1028 (Oct. 6), 1928.

Diphtheria Prevention in Virginia

—A state-wide campaign of diphtheria prevention was inaugurated in January, 1927. Physicians and nurses engaged by the state assisted local physicians in establishing clinics at which toxin-antitoxin was given. About 45,000 children were immunized in 44 counties. Later the plan was changed so as to enlist the aid of school teachers. A small fee for immunization was charged varying from 15 to 25 cents, but for those without means this service was given gratis. In 47 counties there were immunized 147,238 children. The public health nurse and the school teacher did most of the work in the rural districts. It is estimated that there are now approximately 250,000 children immunized with toxin-antitoxin in Virginia.—H. G. Grant and D. H. Anderson, *Virginia M. Month.*, Reviewed, *J. A. M. A.*, 91: 1045 (Oct. 6), 1928.

Training County Health Officers

—The need for medical health officers to man full-time rural health organizations has become acute during recent years. In Tennessee approximately one-third of the rural population is now under full-time health protection. Under the auspices of the department of preventive medicine of Vanderbilt Uni-

versity in coöperation with the Tennessee State Department of Public Health, a course of training in public health for graduates in medicine is offered at Nashville. The primary purpose is to fit graduates in medicine for positions as county health officers and no attempt is made to make specialists. The objectives are to acquaint the medical graduate with the field of public health, to inform him of the communal resources and to develop the point of view of a health officer. The course occupies a total of 12 weeks, divided into two periods of 6 weeks each. The first period is devoted to a short academic course in which public health administration, maternal and child hygiene, communicable disease, laboratory and sanitation, are considered as major subjects. The minor subjects include medical zoölogy, vital statistics, industrial hygiene, mental hygiene, graphic methods and rehabilitation of the handicapped. The second period of the course is spent in the field securing practical experience through association with a local health officer.—J. W. Mountin, *A Plan for Training County Health Officers*, *J. A. M. A.*, 91: 717 (Sept. 8), 1928.

Typhoid Fever due to Oysters—An epidemiologic study has been made of the cases of typhoid fever known to have occurred in Baltimore between October 10, 1926, and February 12, 1927. There are a total of 50 cases in the study

plus 4 additional cases reported from Baltimore County which were associated with the cases within the city. Altogether there were found to be 15 cases of typhoid fever and at least 12 cases of gastroenteritis occurring among those who partook of a supper given October 24 and an oyster roast given November 14, 1926, in Baltimore. In 8 other cases the evidence, although not conclusive, indicated that oysters were probably responsible for typhoid fever.

All cases were visited and a complete history obtained. In the case of the special supper and oyster roast, it was found that oysters were the only article of food which was common to all guests who became ill. No typhoid carrier was found among the shuckers, cooks, and waiters examined. Investigation disclosed the fact that the oysters suspected, although eaten on different occasions, came from a common source, that is, a small village, an isolated community of 700 inhabitants, situated on the seashore in Virginia. Typhoid fever was found to be present in this small community and 56 cases of typhoid fever were reported in the county where the village is located from July 1 to December 31, 1926. Sanitary conditions at the oyster plant were not good.—G. H. Ramsey, G. F. McGinnes and P. R. Neal, *An Outbreak of Typhoid Fever and Gastroenteritis Attributed to the Consumption of Raw Oysters*, *Pub. Health Rep.*, 43: 2395 (Sept. 14), 1928.

LABORATORY

C. C. YOUNG

AN OUTFIT FOR GROUP IMMUNIZATION

Including an Automatic Syringe and a Needle Rack

FILIP C. FORSBECK, M.D.

Massachusetts Department of Public Health, Boston, Mass.

THE injection of any considerable number of persons for the purpose of immunizing them against diphtheria, typhoid fever or other diseases, involves the expenditure of valuable time if accurate dosage and aseptic technic are to be maintained. If a 5 or 10 c.c. syringe is used to inject $\frac{1}{2}$ c.c. of fluid, accurate measurement of the dose is difficult. This factor is important because an inadequate dose may result in an insufficient immunizing stimulus, whereas an excessive amount may produce undesirable reactions. An accurate dose can only be obtained by using a smaller syringe, but the more frequent filling is laborious and increases the chance of contamination.

To reduce the chance of contamination to a minimum, assure accuracy of dosage, and increase the speed and ease of injection, a special syringe and needle rack have been devised.

FIGURE I—THE SYRINGE

DESCRIPTION OF UNITS

The short glass barrel of the syringe (B) is equipped with a spool finger grip of metal (C) designed for the comfort of the operator. The glass plunger (D) is

equipped with a metal thumb ring-grip (G) and a dosage control (F) which regulates the stroke of the plunger so that exactly $\frac{1}{2}$ c.c. or 1 c.c. of fluid may be expelled each time. After injecting, the plunger is reset by spring tension (E). A metal cap is supplied to prevent contamination and leakage when a needle is not in place.

The vials (L) of bacterial vaccine, toxin-antitoxin mixture or other fluid are firmly held in a spring holder with weighted base (N). The metal cannula (M) is provided with an adjustable, conical, protecting cap (K). This is the first unit in a completely closed system which carries the immunizing fluid from the vial to the skin of the individual to be immunized. The cannula is connected by an adapter (J) to a convenient length of small-bore, sulphur-free rubber tubing (I), which in turn is connected to the valve device (A) with another adapter (H). Both adapters have "Vim" locks. The valve device originated with S. W. Adler. It acts on the double valve principle.

No new principle is claimed for the syringe. It is thought, however, that the application is new.

The needle rack (Figure II) consists of a circular metal disc (P) with slots (Q) in which the hubs of the needles fit. The space (S) is not slotted, thus marking the start and finish of the series of needles. The needles are placed in the rack with the bevels of the points upward. The rack rotates on a heavy

FIGURE II—THE COMPLETE OUTFIT

stand (R). The latter is provided with two lugs (T) which project over the edge of the table to prevent slipping. A convenient handle (O) is provided for carrying the rack to and from the sterilizer. It fits the commonly used Sterno outfit and the ordinary instrument sterilizer. Each rack holds thirty needles of the Vim-Luer, square hub type.

PREPARATION

The sterilization of the syringe and rack differs in no way from that of other instruments.

To maintain asepsis after sterilization, it is necessary to assemble the syringe in part, at least, with sterile forceps. First the spring is slipped on the plunger. The plunger is then inserted in the barrel, the valve attached to the syringe and the rubber tubing to the valve. The assembling is completed by joining the cannula to the other end of the rubber tubing.

A few strokes of the plunger will remove any water present. The cannula is then placed in the vial. With the

syringe held below the level of the fluid, the air is replaced by fluid with a few additional strokes of the plunger.

The operator sits at the side of the table, with the rack base conveniently located at the edge. The vial of immunizing fluid is placed in its base between the rack and the individual to be immunized, so as to avoid contamination of the needles with the rubber tubing.

THE OUTFIT IN USE

After expelling the fluid in injecting the first person, one may proceed in either of two ways:

Hold the plunger down until the used needle has been replaced in the rack and a sterile one secured. Then refill the syringe by releasing the plunger. Or, first release the plunger for refilling and then replace needle from the rack, preferably using both hands.

Holding the plunger down while changing needles becomes tiresome. The object in proceeding this way is that the thumb pressure gives added power in twisting needles on and off.

Not to hold down the plunger is easier, however. In this case using both hands gives maximum speed and power.

With either technic one needle after another is used in rotation. The double stand allows the assistant to have a full vial in place, so that when the one in use is emptied, the cannula may be shifted quickly from one to the other. In like manner, the assistant may exchange a used rack of needles with one freshly sterilized without interrupting the physician. Thus, time is saved for all concerned, but particularly for the physician.

After the last person has been inoculated, the cannula is shifted to hot water. The needles are then rinsed out, using the syringe. Thus, the needles and syringe are rinsed at the same time. Since the needles are of stainless steel, they may be conveniently left in the rack.

The actual use of this syringe has

demonstrated the following advantages:

1. Accurate dosage is automatic.
2. The chance of contamination is reduced to a minimum.
3. The speed of injection is greatly increased.
4. The waste of immunizing fluid is reduced.

The actual use of the rack has demonstrated the following advantages:

1. The chance of contamination is reduced to a minimum.
2. The speed and facility of needle change is increased.
3. The operator's fingers do not get sore from changing tightly secured needles.
4. The needles are protected from injury, thus increasing their life.
5. The beveled side of the needle is always up. (A special advantage for Dick, Schick, and other intra-dermal tests.)
6. It is a convenient place in which to store the needles.
7. The needles may be cleaned with ease and speed.

NOTE: The group immunization outfit is manufactured by the MacGregor Instrument Company, Needham, Mass.

Acknowledgments are due W. H. Brockway, John MacGregor, Arthur D. Weston, Dr. Benjamin White, and others for help and suggestions.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Mortality Experience of the First Six Months of 1928—Health conditions in the industrial populations of the United States and Canada during the first half of 1928 have been somewhat better than the average. They have not been as satisfactory as those prevailing during the corresponding periods of 1927 and 1921. The combined death rate for influenza and pneumonia among Metropolitan industrial policy holders was 19.8 per cent higher than last year's figure. The rate for organic heart disease among white policy holders during the first half of 1928 was 139.5 per 100,000 as compared with 130.0 during the like period of 1927, and there was a corresponding rise of the colored

from 217.4 to 239.7. There was an increase of 7.7 per cent for the colored cancer death rate. Among white policy holders the rate was only slightly higher than for the first half of 1927 or 1926.

The diabetes death rate shows an upward trend, particularly among insured urban negroes, being 19.4 per 100,000 for the first half of 1927 and 21.4 for the corresponding months of 1928. The tuberculosis death rate in the industrial population was 96.9 per 100,000 as compared with the 100.3 of 1927. Among white policy holders there was a reduction of 6.1 per cent in the death rate, but among the negroes there was an increase from 237.6 per 100,000 to 242.5. The typhoid fever death rate was lower

in 1928 than ever before, and the situation with regard to scarlet fever, whooping cough and diphtheria showed little change. The measles death rate rose from 7.1 per 100,000 to 8.6 among the whites and from 3.6 to 8.1 among negroes.

There was a drop in deaths from puerperal septicemia among colored women from 13.4 per 100,000 to 9.2. The death rate from alcoholism declined from 3.4 per 100,000 to 3.1. The record for automobile fatalities shows little change in the death rate as compared with the first half of 1927.—*Stat. Bull., Met. Life Ins. Co.*, 9: 1-5 (July), 1928.

Death Rates among Infants of Wage Earners—Infants of wage earners who are insured in the Industrial Department of the Metropolitan Life Insurance Company show very low death rates. In 1926 the Metropolitan death rate for children under 1 year was only 40 per 1,000 lives exposed to risk in contrast with the rate of 78 for the U. S. Birth Registration Area. Between the ages of 1 week and 1 month the death rate for the Metropolitan infants was 146 and that for the registration area 156. The death rates between 1 and 3 months are distinctly lower for children of the Metropolitan policy holders than for those in the birth registration area. After 3 months of age there is not much difference in the rates, and between 6 months and 1 year the rates for both groups are substantially the same, being 27.9 and 27.8.—*Stat. Bull., Met. Life Ins. Co.*, 9: 5-6 (Aug.), 1928.

Age Distribution of Diseases in Relation to Latitude—Deaths from measles, diphtheria, scarlet fever, whooping cough and poliomyelitis tend to be more concentrated in the early years of life as the aggregation of population is increased. For measles and whooping cough, this tendency seems to be inde-

pendent of climate or latitude. In Rhode Island with an urban population of 97.5 per cent, the index of age distribution of deaths from measles is 26. In Ohio with an urban population of 63.8, the index is 5.53. In Oregon with 49.9 per cent urban population, the index is 2.41. For Mississippi with an urban population of 16.6 per cent the index is 1.25.

The age distribution of deaths for scarlet fever, diphtheria and poliomyelitis has a higher concentration in early childhood in warm than in colder climates. In the northern and western parts of the country the age distribution of deaths from these diseases is related to aggregation of population in nearly the same degree as with measles. But in the southern states, despite the sparse population, the deaths from these diseases are concentrated in the early years of life. Thus in Maine, the median age of death from diphtheria is 4.9 years, and in Louisiana, with nearly the same proportion of urban population, the median age is 2.89 years. The per cent of deaths under 5 years from measles is 93.70 for London, 93.35 for New York, 87.38 for Rio de Janeiro and 86.67 for Manila; whereas death rates from diphtheria are 60.91, 71.58, 80.95 and 91.79, showing the highest indices of age concentration for the smaller tropical cities.—James A. Doull, *Variations in the Age Distribution of Mortality and Morbidity from Diphtheria, Scarlet Fever and Certain Other Diseases in Relation to Latitude*, *Am. J. Hyg.*, 8: 633-647 (July), 1928.

Diabetes—A study of two thousand diabetic cases was made in Cleveland between March, 1921, and November, 1927. The incidence of diabetes among patients admitted to the clinic during this period was 2.28 per cent, 46.8 per cent of the diabetic cases being male and 53.3 per cent female. There was a hereditary history of diabetes in 5.3 per

cent and a familial history in 4.5 per cent of the cases. Glycosuria was found in 159 patients with blood sugar below 180, and in 26 with blood sugar 120 or below. Glycosuria was not found in many patients in the presence of high blood sugar, the highest blood sugar level without glycosuria being 390 mg. per 100 c.c.

The general belief that insulin if once used must always be continued is fallacious. In a number of cases from 4 to 76 years of age where the use of insulin was discontinued from 5 to 72 months, the blood sugar content either remained within normal limits or showed a slight rise. Insulin reactions are not wholly due to hypoglycemia, but are found frequently in the presence of hyperglycemia as noted in a case where the blood sugar at the time of insulin reaction was 467 mg. per 100 c.c. Many normal persons have a blood sugar content as low as from 30 to 40 mg. per 100 c.c. The total number of patients with diabetic coma in the series was 85, or 4.3 per cent. Among 59 of these 81.4 per cent lived and 18.7 per cent died. The incidence of syphilis in the entire series was 2.7 per cent. The total mortality was 131, or 6.55 per cent.—Henry J. John, *Arch. Int. Med.*, 42: 217–247 (Aug.), 1928.

Decline in Tuberculosis Mortality
—Figures show that in those countries where coördinated measures against tuberculosis have been continuously applied throughout a sufficiently prolonged period, there is a striking decline in mortality from tuberculosis. The accelerating drop in the tuberculosis death rate greatly exceeds the drop in mortality from all diseases throughout the same period. During the fifty years between 1871 and 1921 the death rate from tuberculosis in Scotland was re-

duced by two-thirds, while that from all diseases was reduced by less than one-half.

In England a comparison of the death rates for several years shows a drop of 14 per cent between 1871 and 1881; in 1891 the death rate had decreased 15 per cent; in 1901 there was a drop of 19 per cent; in 1911 the rate decreased 21 per cent; and during 1921, 20 per cent. Similarly for Scotland the 1881 death rate shows a drop of 17 per cent; that of 1891 a drop of 21 per cent; and that of 1921 a drop of 31 per cent. In Ireland there was an increased tuberculosis death rate of 6 per cent in 1881; a 2 per cent increase in 1891 and 1901; a decrease of 20 per cent in 1911; and a decrease of 25 per cent in 1921.

In Scotland, the deaths from pulmonary tuberculosis in 1871 constituted 11.8 per cent of deaths from all diseases; in 1901 they were 8.7; and in 1921, 6.2 per cent of deaths from all diseases. Likewise in England the pulmonary tuberculosis deaths in 1871 were 10.5 per cent of deaths from all diseases; they were 7.5 per cent in 1901; and 7.1 per cent in 1921.

There was also a decline in the tuberculosis death rate in other countries. In Denmark the mortality rate for 1901 was 210 per 100,000, and in 1922 it was 95 per 100,000. In New York, taken as a representative of antituberculosis work in the United States, the death rate for 1907 was 238 per 100,000, and in 1921, in spite of an increase of a million and a half in population, the death rate from tuberculosis was 106 per 100,000. In France, before the war the death rate was about 400 but in 1921 at the beginning of the antituberculosis movement it was 286.—Sir Robert Philip, *Causes of the Decline in Tuberculosis Mortality*, *Pub. Health*, 41: 336–344 (Aug.), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Demonstration of Vacuum Degasification Process for Sewage Settling Tanks—Sewage plant troubles, especially with reference to odors and foaming, were discussed at the sewage field conference held in Cleburne, Tex., August 27, called by Dr. F. E. Giesecke, director of sewage research, A. & M. College, College Station, Tex., and Dr. J. C. Anderson, State Health Officer, Austin, Tex. More than fifty towns were represented by the 130 registrants who gathered to discuss and examine the new vacuum degasification process recently installed at the Cleburne sewage disposal plant by T. B. Sims, superintendent of city water and sewage department, and James G. Taylor, city water commissioner.

Ever since the first information was given out about the unusual results from this process, inquiries have been coming in to the engineering division of the State Department of Health from mayors, city managers, sewage plant operators, chemists, engineers, and others interested in the all-absorbing problem of stream pollution and sewage disposal.

The discussions developed, after inspection of the plant, were practically unanimous in favorable comment as to the extensive results accomplished. A cross-section of the opinions expressed gave special attention to:

1. The unusual clarity and excellent physical appearance of the effluent after treatment with the vacuum degasification arrangement

2. Simplicity of the automatic vacuum degasification pumping device in the dosing chambers

3. The daily gravity removal of the sludge from the surface of the Imhoff gas vents, reversing normal withdrawal of the sludge from the bottom of the tanks

4. Hastening of digestion by producing more

favorable conditions for bacterial action through continuous removal of gases as they are formed

5. The noticeable absence of offensive odors from units in the plant, more especially the lagoons, containing the sludge removed from the surface of the Imhoff tank

Generally it was agreed that the process is accomplishing some improvement. However, it was also evident that the biggest task is to extend studies in determining physical and biochemical reactions in the tank created by the constant vacuum, all of which is necessary to determine the design, shape, and size of tanks more workable for this process. Work has already been started at the A. & M. College sewage experiment station under the direction of Professors F. E. Giesecke and E. W. Steel for extending these studies in coöperation with the engineering staff of the State Department of Health. Assurance has also been given, through Dr. E. P. Schoch, of the University of Texas extending research work in perfecting this process.—State-wide Sewage Field Conference Held at Cleburne, Tex., Aug. 27, 1928.

River Pollution—In the January, 1928, issue of the *JOURNAL* (p. 71), there appeared an editorial on the sanitation of waterways, in which was mentioned the desirability of further coordinating efforts to solve the rivers pollution problem in England through the appointment of a joint administrative advisory committee and of a research board. In the September 20, 1928, issue of *Water and Water Engineering* the first report of the joint advisory committee is given.

This joint committee, which is reporting to the minister of Health and the

minister of Agriculture and Fisheries, undertook its task by first considering the question of "the machinery best suited to administer the law with regard to the pollution of rivers and streams." A review of the acts which convey authority to enforcing agents for the abatement of river pollution is then given. The authority seems to be ample, but pollution of waterways continues.

The committee has received evidence to the effect that to prevent pollution "a body specially charged with the administration of the Acts and acting throughout the whole or the greater part of a river basin is far more effective than a body operating in a limited area and occupied with a large variety of other work." Further, proper administration can be secured only when the body in authority has supervision over a river as a whole, including its tributaries. Another conclusion of interest is that the area under jurisdiction of any rivers board should be sufficiently large to permit the employment of skilled officers, but still not so large as to make it impossible for the chief officers to keep themselves informed as to the existence of any pollution.

Effect of Salt on Sludge Digestion

—This paper treats of the effect of increasing amounts of sodium chloride upon the rate of organic decomposition in sewage sludge by bacteria and shows that it is, progressively, (a) indifferent, (b) stimulating, (c) retarding, and (d) toxic.

The author gives tables and charts showing the effect of sodium chloride on domestic sewage sludge in mixtures of 2, 5, 10, and 20 gm. per liter of sludge containing 1 part of ripe sludge to 2.3 parts of fresh solids. He concludes that the effect of salt upon the rate of decomposition of sewage sludge is only slightly noticeable with the addition of 5 gm. per liter of sludge, but with larger amounts the destruction of volatile mat-

ter and total gas production decrease markedly. The composition of the gas changes greatly with the addition of salt; with the larger quantities of salt practically no methane is produced. Mixtures of salt and sulphates appear to be somewhat stimulating.—Willem Rudolfs, *Pub. Health Rep.*, 43: 874–881, 15 (Apr.), 1928. Abstr. O. C. Hopkins.

Treatment of Slaughterhouse Waste in Holland—The important features of the plant which treats a small quantity, 30,400 gallons, of strong slaughterhouse wastes are: (a) surface aeration produced by revolving street brushes which are submerged from $\frac{1}{4}$ to $\frac{1}{2}$ inch in the liquid. Submerged wooden paddles keep currents moving; (b) great reduction in volatile matter, oxygen consumed and alkalinity and considerable formation of nitrates. Reduction in alkalinity is 68 per cent. American results taken from *Public Health Bulletin No. 132* range from 19.5 per cent to 27.5 per cent reduction for domestic sewage; (c) flexibility of operation; aeration can be increased by dipping the brushes a little deeper; and (d) low construction and operation costs are claimed.—Willem Rudolfs and H. Kessener, *Pub. Works*, 59, 4: 151–154 (Apr.), 1928. Abstr. L. M. Fisher.

The Relation of the Type of Soils of Alabama to the Distribution of Hookworm Disease—Earlier experimentation with soils in Porto Rico and Maryland had demonstrated distinct differences in the percentage of hookworm ova that develop to infective larvae in humus, sand, loam and clay. With this as a clue, soils representative of the different soil belts in Alabama were tested in the laboratory to determine their effectiveness in rearing larvae. Typical sandy soils permitted a yield of infective hookworm larvae averaging 43 per cent of the ova introduced, whereas for clay soil the average was closer to 5

per cent, the degree of efficiency of the soils being "directly related to their textures." Hookworm surveys on children from different parts of Alabama showed that the incidence is greatest in the two sandy provinces, the Upper and Lower Coastal Plains, and that hookworm disease is largely limited to the latter. Light infestations were constantly encountered among children who had lived all or nearly all their lives in soil provinces in which fine, heavy clay soils predominate, but in no instance did these children have heavy infestations.—D. L. Augustine and W. G. Smillie, *Am. J. Hyg.*, 6: 36-62 (Mar. supplement), 1926. Abstr. N. R. Stoll.

Treatment of Vegetable Refuse: A New Process—Incoming vegetable matter is first pulverized; the pulped mass is delivered continuously to a separator where heavy foreign matter, such as glass, settles out in agitated water. The vegetable matter is then drained on moving copper gauze, which conveys it to heavy rolls for complete crushing. A second pair of rolls removes the free water, leaving the material comparatively dry. A readily salable and hygienic product forming a valuable addition to agricultural economics is produced.—Anon., *Surveyor*, 73, 1885: 297 (Mar.), 1928. Abstr. W. M. Olson.

Town Planning in Sweden—Although there are only some 120 towns in Sweden, fixed plans have been in use since the beginning of the 16th century. Perhaps the first building and town planning law applicable to an entire country was the law passed in Sweden in 1874 which "embraced only the technical regulation for the planning and building of towns in conformity with the requirements of hygiene, comfort, communication and protection from fire." Some 4,000 plans have been made since the passage of this law.

The town plan was adopted by town authority, with final approval except in minor cases resting with the King. The plan was usually drawn on a scale of one-two thousandth part of the actual dimension and included a topographical map. General building regulations such as building height, zoning, financing, and law enforcement were definitely provided in law of 1907, which influenced to some extent the English Town Planning Act of 1909.—A. Lilienberg, *Surveyor*, 73, 1892: 465-466 (Apr.), 1928. Abstr. F. J. Lavery.

Industrial Waste Work of the Sanitary District of Chicago—This article sums up the results and recommendations of studies and tests made on the three major industrial wastes produced in the Sanitary District. These wastes are classified as packing house, tannery and corn products. Chemical industrial wastes from the Sherwin-Williams Paint Company are discussed also.

The Stockyards Testing Station was operated from 1912 to 1918. Studies were made of fine screening, sedimentation, chemical precipitation, trickling filters and activated sludge. Best results were obtained by activated sludge treatment. An aeration period of 9 hours and 3.5 cu. ft. of air per gal. were required. Activated sludge was filter-pressed in a recessed-plate press.

The Tannery Testing Station was built in 1920 and operated several years, and included tanks and filters for studying fine screening, sedimentation, activated sludge treatment, cinder and sand filters and filter pressing of sludge. Results tend to show that biological treatment would be uneconomical and inadvisable for the 30 tanneries on the North Branch, but screening and sedimentation should be accomplished at most of the individual houses. Further study on the use of alum as an aid to sedimentation is being made.

The Corn Products Testing Station

was built at Argo in 1920 and operated to 1926. Sedimentation tests were made in an Imhoff tank, but the removal of suspended matter was practically negligible, and settling did not seem to be of any benefit for further treatment biologically. The activated sludge process was not satisfactory. A trickling filter 7.5 feet deep gave satisfactory effluents at rates of 700,000 gallons per acre per day, and stood overloads in concentration more successfully than the activated sludge process. Trickling filters were recommended as the most successful type of treatment.

Attention was also given to the possibility of recovery of some of the waste products in the factory. A remarkable reduction of wastes occurred in 1926 when all of the waste waters from the starch and gluten settlers were returned to the process, recirculated and finally removed as a valuable feed. This recovery of wastes has reduced the treatment problem to 18 per cent of its original size.—F. W. Mohlman, *Water Works*, 67, 4: 163-166 (Apr.), 1928. Abstr. R. J. Faust.

Removal of Phenol Wastes from Gas Plants—The Rochester Gas and Electric Corporation cooperating with the City of Rochester, N. Y., and the State Department of Health experimented with the addition of phenol-bearing wastes from ammonia stills to city sewage. One part of waste was diluted with 1,000 parts of sewage. The mixture was circulated for 3 hours in a closed system, to simulate the flow through a sewer. A reduction from 5.3 p.p.m. to 5.0 p.p.m. of phenol occurred, indicating that the destruction or absorption of phenol by the raw sewage was slight. The alkalinity, pH and bacterial flora were virtually unchanged.

A mixture of the same proportions was treated in the one-half million gallon Imhoff tank disposal plant at Char-

lotte for 10 weeks. A well digested sludge, easily dewatered, was obtained. The pH was constant, free ammonia increased, number of bacteria increased, and grease and sulphur trioxide decreased in the sludge. It is concluded that "the addition of the ammonia still waste to sanitary sewage in the rate of 1-1,000, thereby adding about 2.2 p.p.m. of phenol, can be carried on successfully with no deleterious effect upon the sludge digestion and plant operation of Imhoff tanks." The absorption of phenol in the Imhoff tank is negligible.

The amount of phenol removed by trickling filters and by both Imhoff tanks and trickling filters was found to vary with the concentration of phenol. The following table summarizes the data presented:

TRICKLING FILTERS

(Sanitary sewage normally having 3.0 p.p.m. phenol)

Ratio of waste to sewage	none	1-210	1-420	1-880
% phenol reduction	26.7	24.3	38.3	28.9

IMHOFF TANKS AND TRICKLING FILTERS

(Sanitary sewage normally having 3.6 p.p.m. phenol)

Ratio of waste to sewage	none	1-210	1-420	1-850
% phenol reduction	42.9	35.1	42.7	31.1

Conclusions: In large Imhoff tank plant operations, ammonia still wastes may be added to sewage at a ratio of 1-2,000 with no ill effects upon operation, but only a relatively small amount of phenol, if any, is destroyed. Those treatments employing oxidation, such as trickling filters, produce a varying amount of phenol destruction.—Louis Shnidman and Linn B. Bowman, *Gas Age-Record*, 61, 18: 626-628 and 634 (May), 1928. Abstr. J. I. Connolly.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

The Lessening Menace of Benzol Poisoning in American Industry— This contribution presents a very interesting résumé of the present status of the use of benzol in industry. Dr. Hamilton reviews the practice in those industries which was regarded as being the chief users of benzol, namely, rubber, artificial leather, sanitary can manufacture, dry cleansing and the paint industries. It is pointed out that in the rubber industry benzol cement is being largely replaced by rubber latex, that is, the uncoagulated juice of the rubber tree. In the artificial leather industry toluol has, to a very large extent, replaced benzol, while in the making of sanitary cans rubber latex is used in order to render the cans air-tight. In the dry cleaning industry "Stoddard's Solvent," as well as ordinary naphtha, has come into use, while in the paint industry toluol is largely substituted for benzol. It is, of course, not to be understood that benzol is exclusively eliminated from the previously mentioned industries.

Dr. Hamilton points out that it is the belief of many insurance and industrial officials that benzol will be replaced eventually by other non-injurious materials.—Alice Hamilton, *J. Indust. Hyg.*, X, 7: 227 (Sept.), 1928. L. G.

A Case of Hematuria from Shoe Dye Poisoning—Shoe dyes have been the causative agent of blood pathology. In a recent article, Haft (*J. A. M. A.*, March 10, 1928) notes some 61 cases reported in the literature. The present report deals with a case of shoe dye poisoning complicated with hematuria. This case occurred in a student, aged 17,

who wore freshly dyed shoes but seven hours. Cyanosis and headache were the chief symptoms. The following day the urine presented a clear, dark, amber appearance, changing two days later so that it then presented a completely bloody picture. At the end of five days of treatment no red blood cells could be found microscopically in the urine. Analysis of the shoe dye revealed aniline to be the source of the poisoning.—O. J. Schmitt, *J. A. M. A.*, 91, 10: 726 (Sept. 8), 1928. L. G.

Effect of Antiseptic Sprays on the Bacterial Content of Air—In the series of studies here reported *B. coli communis* was used as a test organism. The bacteria were grown in large quantities and then made into a homogeneous emulsion with 4 parts of saline to 1 part of culture. Measured portions of this emulsion were sprayed into a room of approximately 5,000 cu. ft. content, the windows and doors being closed throughout the studies. The spray was directed into the blast of a powerful electric fan and so dispersed throughout the room. Ten minutes after the onset of spraying, that is, about 9 minutes after spraying was completed, agar plates were exposed for a period of 2 minutes at various locations in the room. When antiseptics were being tested these were sprayed during two periods of a duration of 1 minute each in the interval between bacterial dissemination and plate exposure.

It was found as a result of these experiments that the two antiseptics tested exerted a real bactericidal effect. In general, it was found that this effect depended upon many factors, the most important of which were the antiseptics

used, the degree of dilution, and "the age, exposure, etc., of the antiseptic."

It is pointed out in conclusion that the use of antiseptic sprays in crowded workrooms is justified but that the experimental conditions utilized in this study must be borne in mind in a consideration of this problem.—S. R. Douglas, Leonard Hill, and Wilson Smith, *J. Indust. Hyg.*, X, 7: 219 (Sept.), 1928. L. G.

Moffat Tunnel Ventilation for Steam Locomotives (See paper entitled "Ventilation Experiments in the Moffat Tunnel," by McElroy and Betts, *Engineering News-Record*, Vol. 99, No. 24, December 15, 1927)—The Moffat Tunnel on the Denver and Salt Lake Railway is approximately six miles long. It was found necessary to provide ventilation in order to reduce the temperature and smoke content of the tube while in use. Two fans are provided, one as a reserve unit. These are located in the east portal of the tunnel. The design provides for a current of air, moving at a velocity of 10 to 14 M.P.H. in a direction opposite to that of the motion of the train. A unique portion of the equipment is the arrangement of dampers so as to yield an east or west bound air current as desired. This is accomplished by means of gates, 16x24 ft., operated by 3 H.P. motors, geared to an operating pinion which engages a curved rack on the gate frame. By the proper opening and closing of these gates it is possible to effect either an east bound or west bound air current as desired. It is to be noted that with such a scheme as this the smoke is carried along the full length of the train, instead of being blown or drawn ahead of the locomotive. With the present equipment it would, of course, be necessary to keep the train speed from 10 to 14 M.P.H., in order to avoid this. Such a slow speed is undesirable. On the other hand, to increase the velocity of the air

current to 20 M.P.H., in order to permit a train speed of 15 to 18 M.P.H., would require a power plant of more than 4,000 H.P., which would be far from economical.—*Eng. News Rec.*, 100, 26: 994-995 (June 28), 1928. L. G.

The New Factories Bill—This contribution discussed briefly some of the provisions of the new Factories Bill which is expected to come before the next session of the British Parliament. It is expected that the provisions of this bill will make conditions in British factories more congenial, and solve to some extent the strained relations between capital and labor. In general, according to the author of this paper, it seeks to remove from the control of the local authority much work which he has conducted since 1901.

The local authorities will continue to exercise certain rights of entry, and in particular in the preparation, manufacture and packing of food the responsibility rests largely with the local authorities. It is to be noted, however, that if this bill becomes law it will be the first piece of legislation which has removed any premises except crown buildings from the control of the local authorities.

One section of the bill deals with the amount of cubic space required per worker and increases the requirements from 250 to 400 cu. ft. It also provides that only 14 ft. of ceiling may be considered in making this computation.

The heating standard required by the new legislation is 60° F. The installation of thermometers is a requirement of the law. Ventilation is dealt with by the requirement that "a constant supply of fresh air must be provided in each workroom." Lighting is discussed in one section of the new law, not quoted except that it is required that windows and skylights be kept clean.

It would appear that there is considerable overlapping of the work of the fac-

tory inspector and the sanitary inspector, a fact emphasized by Mr. Raimes.

It seems obvious, also, from the contents of this paper, that certain of the items in the legislation might with advantage be more clearly defined, such as, for example, "sufficiently lighted and ventilated" and "conveniently accessible."—C. Raimes, *J. Roy. San. Inst.*, XLVIII, 10: 577–580 (Apr.), 1928.

L. G.

Method of Action of Silica Dust in the Lungs—After a review of the literature bearing on this subject, the authors of this paper conclude that silica is a constituent of many plant and animal tissues and that the silica ion is not toxic to animals. Moreover, silica in stable combination and crystalline silica appear to be harmless. It is colloidal silica which is harmful, and the opinion of the writers of this contribution is that silica is harmful chiefly because of its powerful colloidal properties.—P. Heffernan and A. T. Green, *J. Indust. Hyg.*, 10, 8: 272–278 (Oct.), 1928.

L. G.

Inhalation Experiments with Certain Lacquer Solvents—This paper presents the results of studies on the effects of various solvents used in paints and lacquers on the test animals exposed to them. The substances studied were toluol, xylol, gasoline, ethyl acetate, butyl acetate, amyl acetate, ethyl alcohol, butyl alcohol, steam distilled turpentine, and spraying lacquer distillate. Guinea pigs were used as the test animals. They were exposed in the gassing device by means of which known concentrations of gas could be continuously fed to the chamber. Observations and studies were made on the weight of the animals, their blood characteristics, and the urine. As a result of this study the

authors have divided the substances tested into three groups as follows:

1. Those usable with safety in concentrations usually employed or possibly in somewhat higher concentrations as ingredients of brushing or spraying lacquers. Ethyl acetate and amyl acetate, and possibly butyl acetate, would be placed in this class.

2. Those usable with safety in present concentrations but to be increased with caution as possibly harmful if increased materially. Here would be listed gasoline, turpentine, and xylol.

3. Those for which the present practice probably represents nearly the upper limit of safety in use as spraying lacquer constituents. In this group are toluol and butyl alcohol.—H. F. Smyth and H. F. Smyth, Jr., *J. Indust. Hyg.*, 10, 8: 261–271 (Oct.), 1928.

L. G.

The Gravimetric Determination of Dust Inhaled by Workmen—In the making of determinations of the dust content of the atmosphere of work places, the sampling apparatus is usually set up at the proper point, and by means of a fan or suction device the room air is continuously drawn through the appropriate dust filter. To the author of the present paper this seems to be a fallacious procedure, chiefly for the reasons that the human being inspires and expires in an orderly sequence. The sampling instruments do not therefore simulate actual conditions. Further, the position of the sampling tube and the direction of the flow of air constitute important considerations in his mind. For these reasons he has devised the instrument described in this article. The instrument is so arranged that it may be attached to a person's head. Two tubes are placed in the nostrils, and the inhalation of the air filters it through the cotton or glass wool which constitutes the filtering medium.—A. I. Burstein, *J. Indust. Hyg.*, 10, 8: 279–291 (Oct.), 1928.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Destruction of Botulinum Toxin by Milk Bacteria—Attention is directed to the fact that botulism is very rarely attributed to the consumption of milk and milk products contaminated with *Cl. botulinum*. Although fresh milk may ordinarily be used before bacterial growth has been sufficiently extensive to be dangerous from the standpoint of botulinum poisoning, such is not the case with cheese and certain other milk products. The exclusion of cheese as an agent in the dissemination of botulism cannot be explained by the inability of *Cl. botulinum* to grow in the product because of its acidity, since in many types of cheese the reaction is not sufficiently acid to inhibit the growth of this organism. In this paper it is shown that botulinum toxin is destroyed by *S. lactis*, *Lactobacillus casei* and *Proteus vulgaris*, which are organisms occurring in milk and milk products. The authors here previously demonstrated that *B. coli*, *B. communior*, *B. aerogenes* bring about destruction of botulinum toxin. It is believed that these results explain in part the fact that milk and dairy products are seldom if ever agents in the dissemination of botulism.—J. M. Sherman, C. N. Stark, and Pauline Stark, *J. Dairy Sci.*, 11: 352 (Sept.), 1928.

The Bacterial Content of Orange Sherbet—Ices or sherbet mixes, which have been made from high-grade products, should contain very few bacteria before processing. If processed in clean equipment and carefully aged at low temperatures, the bacterial content of the finished product should also be relatively low. If the bacterial content

of a sherbet or a water ice is high, the most likely sources of contamination are poorly washed utensils, improper aging temperature, or, in case of a sherbet, the addition of ice cream mix or dairy products of poor quality. In this paper results are given to show the bacterial content of 21 samples of orange sherbet manufactured in Kansas, Missouri and Nebraska and representative of the product sold in the middle west. The plate counts per gram of sherbet ranged from 80 to 1,100,000. Only 2 samples contained bacteria in excess of 100,000 per gm. and 13 samples contained less than 10,000 bacteria per gm. The 6 remaining samples contained between 15,000 per gm. and 64,000 per gm. In view of the limited information at hand, it would not be feasible to suggest any definite figure as a basis for judging the bacterial content of sherbets. The relatively low bacterial content of a water ice or sherbet enables the detection of equipment contamination of lesser magnitude than would be possible with other products such as ice cream or milk. In regard to pasteurization of water ice or sherbet mix the author states that, although the pasteurization of these products may not be so imperative as it is for ice cream mix, the process is sufficiently advantageous to more than justify its adoption.—A. C. Fay, *J. Dairy Sci.*, 11: 404 (Sept.), 1928.

A Defect in Milk Due to Light—It has been observed that an "off" flavor develops in milk which has been kept in an outdoor icebox, frequently an open box, or directly exposed to sun-

light and daylight on a windowsill. Previous investigators having reported the production of a "tallowy" flavor on exposure of milk to direct sunlight, this investigation was conducted using diffused light to determine to what extent this produced in milk the "tallowy" or "cardboard" flavor. Duplicate samples were employed, kept in flasks or bottles stoppered with cotton or covered with paper, one sample being kept in the dark during the experiment. Temperatures employed were just above freezing. Characteristic cardboard flavor developed in samples exposed to daylight for 8 to 26 hours. No flavor developed in the sample kept dark. Skim milk in contrast to whole milk or cream does not develop the "off" flavor. Pasteurized samples developed the objectionable flavor more rapidly than raw milk. The reaction which develops without the aid of enzymes or bacteria appears to be due to the catalytic action of light.—William C. Frazier, *J. Dairy Sci.*, 11: 375 (Sept.), 1928.

The Effect of Ethylene upon the Vitamin B Content of Celery—In this experiment young rats of the same litter were paired closely as to weight and placed on a vitamin-B-free diet. Ethylene treated and board-blanching celery were fed in known quantities and check animals from each litter maintained. The results did not indicate that either method is superior in conserving food value although it was shown that ethylene is not injurious to the vitamin B content of celery. This work is interesting in view of its bearing on the commercial use of ethylene gas to effect the ripening of tomatoes and other fruits and vegetables.—M. F. Babb, *Science*, 68: 231 (Sept. 7), 1928.

The Copper Content of Milk—The varying amounts of copper found in milk by investigators in different lo-

calities has suggested the possibility of the influence of the copper content of native feeds. Milk was collected from 4 states—Iowa, Montana, South Dakota, and Kentucky—and analyzed, the copper content varying from 0.26 to 0.52 mg. per liter. The copper content of milk from a herd of Toggenburg goats was found much lower than cow's milk, ranging from 0.19 to 0.25 mg. per liter, while sheep milk was found to contain about the same amount of copper as cow's milk, 0.45 to 0.50 mg. per liter. Four common brands of condensed or evaporated milk were found to contain copper in greater amounts than probably occurred in the original raw material. This variation can be traced to the amount of copper surface exposed to the milk product. The possibility of contamination with copper during analysis was always checked by means of equivalent quantities of copper-free water which were treated in the same manner as the milk, and copper was determined by the xanthate colorimetric method as modified by Supplee and Bellis (*J. Dairy Sci.*, 1922, v. 455). It is apparent that the variation in copper content of native feeds, such as the grass in Kentucky, has little or no effect.—G. N. Quam and Arthur Hellwig, *J. Biol. Chem.*, 78: 681 (Aug.), 1928.

The Influence of the Administration of Aluminum upon the Aluminum Content of the Tissues, and upon the Growth and Reproduction of Rats—Rats on adequate normal diet were fed 2 mg. aluminum as potassium aluminum sulphate per rat per day in biscuit for 100 days. The rats were killed and the organs analyzed by a colorimetric method devised by the authors (*J. Biol. Chem.*, 78: 595 (Aug.), 1928). Control rats showed small amounts of aluminum in the organs which were but slightly increased in those rats which were re-

ceiving daily doses of the aluminum compound. The difference is most apparent in the liver and brain tissues. The intraperitoneal injection of 4 mg. of aluminum had no ill effect on the rats and the analyses of their tissues showed marked increase in the aluminum content of the liver. Rats on a diet made as free from aluminum as possible were analyzed, results showing small amounts of aluminum still present. The administration of 2 mg. of aluminum covered four generations of rats during which time the growth and reproduction curves compared well with controls, indicating that the addition of aluminum to the diet had little influence.—V. C. Myers and James W. Mull, *J. Biol. Chem.*, 78: 605 (Aug.), 1928.

A Comparison of Certain Methods for Determining the Sanitary Quality of Ice Cream—It is pointed out in this article that there are three bacteriological tests available for determining the sanitary quality of ice cream: (a) total count of bacteria; (b) colon group test; and (c) anaerobic spore test. A comparative study of the three methods is reported. A total of 124 samples of commercial ice cream was obtained from producers and retailers in Seattle, Wash., and examined by these three bacteriological methods. The factory samples (24) gave low counts, 87 per cent under 100,000 and 100 per cent of them under 500,000. Of the dispensers' samples (100) only 31 per cent fell below 500,000, while 69 per cent were above. Since most of the ice cream dispensed was produced in the factories considered, and since 94 per cent of the samples were pasteurized, it appears obvious that there was a tremendous increase after the product left the factories, due either to multiplication or contamination, or both. The total count reveals the results of contamination and of subsequent multiplication of the bacteria introduced, but

it does not distinguish between the two. It was found that 92 per cent of the factory samples contained less than 10,000 organisms of the colon group per c.c. while only 68 per cent of the dispensers' samples contained less than 10,000 per c.c. The colon group test functions like the total count, but it is somewhat more specific in indicating insanitary conditions. It was found that 4 per cent of the factory samples and 14 per cent of those from dispensers contained anaerobic spores in 3 out of 5 tubes inoculated with 1 c.c. of ice cream. The anaerobic spore test shows insanitary conditions only but in the case of ice cream it fails to distinguish between the spores introduced through insanitary conditions and those added with the sugar. For freshly pasteurized products the first two methods are useless except for controlling pasteurizing efficiency; they have distinct value for testing subsequent contamination; the last method reveals contamination in both pasteurized and unpasteurized products.—John Weinzirl and L. S. Harris, *J. Dairy Sci.*, 11: 284 (July), 1928.

The Influence of the Administration of Aluminum upon the Aluminum Content of the Tissues of the Dog—Dogs on a normal diet were found to contain small amounts of aluminum distributed in the liver, heart, kidney and spleen. Dogs administered 230 mg. of aluminum daily for 90 days were killed and the tissues analyzed. Figures showed little difference in the aluminum content over those on the normal diet and these experiments included two dogs which had been fed 7 gm. of aluminum phosphate daily. The most notable increase in aluminum was in the case of the liver, an average of 0.27 mg. aluminum per 100 gm. against an average of 0.15 mg. for the control. Seventy mg. of aluminum administered intravenously and intra-

peritoneally in 5 mg. daily portions remained in the tissue for a long time, a marked increase in aluminum content being found in 8 and 34 days after the last administration. It is concluded that when aluminum is present in the tissues it is slowly excreted and that when aluminum compound is administered orally to dogs the absorption of aluminum is very slight.—V. C. Myers and Dempsey B. Morrison, *J. Biol. Chem.*, 78: 615 (Aug.), 1928.

The Solubility in the Stomach and Duodenum of Aluminum Compounds Found in Baking Powder Residues—To answer the question as to whether the residues in biscuits made from aluminum baking powder are dissolved in the human subject, experi-

ments were undertaken in which test biscuits composed of 100 gm. of aluminum baking powder biscuit with 400 c.c. of water were given. Eighteen subjects were studied in which it was found that the gastric contents in soluble form contained from 2 to 20 per cent of the aluminum administered. In 6 of the subjects the total aluminum was determined and the soluble aluminum on an average was found to be 25 per cent of that administered. The duodenal contents of 4 subjects were examined, indicating solubilities of 10.7 to 29.9 per cent. Figures led to the conclusion that if aluminum is absorbed this absorption probably does not take place in the stomach.—V. C. Myers and John A. Killian, *J. Biol. Chem.*, 78: 591 (Aug.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M. D.

Special Supervision for Non-gainers—In an institutional group of underweight children usually there are a certain number who refuse to gain despite the regular routine under which the majority gain. With such a group as this, at the Ridge Farm Preventorium, intensive study was carried on to find out, if possible, the causes of failure to gain; methods of changing diet and activities to cause a gain; and, lastly, to formulate suggestions for the preventorium to carry out for further treatment of similar cases.

Of the 10 children studied, 8 had physical defects of some description which might handicap their gaining. Since these could not be corrected at this time, methods of diet and hygiene were planned. The 10 girls were not eating a sufficiency of foods principally because of an inconsistent intake.

Over a period of days, the amount of food eaten varied considerably from day to day. Sleep was inadequate, not because of the plans of the preventorium but rather because the children were not actually sleeping during the allotted number of hours.

With these conditions apparent, the caloric value of food eaten was increased, not only by quantity of servings, but also by the use of concentrated foods. The intake was so regulated that the daily amount necessary was furnished. More relaxation and more hours of sleep were planned. Under such a program, the children made at least double the expected gain, except in one case. Through this type of study with difficult gainers, it is evident that direct supervision over this group is of great value. Remembering that most of the children had physical

handicaps and that these might be a factor in their resistance to gains, it is advisable to require correction of physical defects before admittance to a preventorium. If this provision is not made, it would be economical for the institution to employ a special worker to supervise the group of those not "free to gain."—Nellie Hord and Lydia J. Roberts, Ph.D., Results of Dietary and Hygiene Control of Ten Non-Gaining Preventorium Children, *J. Am. Dietetic Assn.*, IV, 2 (Sept.), 1928.

Maintaining a Clean Mouth—

Few people use the toothbrush conscientiously; that is, their thoughts are not concentrated upon what they are doing, but are far away planning their day's work, and they brush energetically only those areas which are most accessible. The length of time consumed in the toilet of the mouth also depends entirely upon how early the individual has arisen; if he is in a hurry, the brushing of the teeth is that part of the morning toilet which will be shortened to make up for lost time.

The unconscious manner and even slipshod method employed by the majority of patients in cleaning their teeth are responsible for the unsanitary and diseased condition of the mouth so often encountered. We should tell our patients that they must consult a mirror after or even while brushing their teeth in order to be certain that they have removed all the white deposits or plaques from even the most inaccessible areas. When they manicure their nails, they do not gaze up into the sky but concentrate their attention upon what they are doing, and their teeth are surely worthy of a similar effort.

The value of dental cosmetics in the form of tooth-pastes, powders or mouth washes is greatly exaggerated in the minds of the public. Many believe implicitly in the advertisements of the manufacturers and are often surprised that these remedies do not fulfil their promises. They frequently regard the toothbrush merely as an instrument to spread the tooth-paste or powder upon their teeth, forgetting that the principal function of the toothbrush is to remove the bacterial plaques and food debris.

It is perfectly natural for the patient to believe that when the gum bleeds he has injured it, and therefore he exercises greater care in the use of the toothbrush. He procures softer and softer brushes, some patients even going to the extreme of believing it to be

impossible to use a toothbrush and attempting to clean the teeth with a handkerchief or cotton. This leads to extremely unsanitary and pathological conditions. Therefore, impress the fact upon the patients that those areas in which the tissues are inflamed and bleed readily need more, not less, brushing; that they need more massage, and that only in this way can they hope to retain their mouths in a physiologically clean condition.

Charles F. Bodecker, D.D.S., F.A.C.D., *The Dental Digest* (Sept.), 1928.

Factors in the Decay of Teeth—

In the annual inspection of the school children of Rochester, a high incidence of dental caries was found. This corresponds roughly to observations elsewhere in the northern states. In order to evaluate the possible etiologic factors, two groups of children were selected for comparison: 25 with perfect or nearly perfect teeth and 25 with marked dental caries. It seemed probable that the differences would be most striking if extremes were chosen.

The difference in the data obtained in the two groups is not so striking as one would expect. The only feature that seems to be of definite etiologic significance in preventing decay of teeth is a diet composed largely of fruits and vegetables. Heredity, infectious diseases and care of the teeth appear to be of little, if any, significance.

Louise O. Kappes, M.D., *Am. J. Dis. Child.*, Aug., 1928.

School Strain and the Underweight Child—In the school studied during November, 1927, 67 per cent of the pupils were underweight. This condition was assumed to be due to strain induced by school work and the problem was approached on that basis.

The community served by the school was composed of agricultural and industrial classes. The children were transported to school in busses and were obliged to remain in school until 3.10 P.M.

As a demonstration two groups of 8 children each were formed—the test group and the control group. The control group continued their school work in the usual manner, save that they were weighed and measured weekly.

Tuberculosis among Young Women—Analysis of tuberculosis mortality during the last decade by age periods shows the following:

DECLINE IN TUBERCULOSIS MORTALITY

Age	Per Cent
5 years	over 50
5-14	41
15-25	18
25-44	42
65 and over	31
In general	36

The one age group from 15-25 has made the least progress. Considering this group, we find great disparity between the male and female, the death rate for girls of ages 15-19 being 75 per cent higher than for boys, and in the age group of 20-24 the death rate for women being 20-25 per cent higher than for men.

The Metropolitan Life Insurance Company's experience has shown this same lack of decrease since 1915. They say: "Contemporaneous with a declining death rate, something has occurred within the past 15 years to cause the mortality among the young white women to be higher than that of young white men." This experience has not been true in England and Wales, where the greatest reduction has been among young women of the age group 15-25 years.

The article continues:

What is the answer? Nobody knows. Various causes are adduced by many writers. The increased industrialization of women which took place during the war years, the extra curriculum activities of high school and college students, a different and more virulent type of disease at the younger ages, jazz parties, late hours, the scanty clothing of present-day young women, the physiological changes following the adolescent period, the dieting fad—all these in varying degree may have their part in the result.

Whatever the cause, or causes, the situation is with us and is perhaps the most important phase of the tuberculosis problem in the United States today.

The nursing profession is one that must assist in coping with this situation, since they

recruit their ranks from young women at these very ages. They must recognize, therefore, that they are dealing with a segregated group which have the highest mortality from tuberculosis in the entire population, and should make provision for reducing that menace to a minimum.

The few studies made on the incidence of tuberculosis among nurses in training show that the rate is much higher among them than among young women of the same ages in the general population. Of the nurses receiving aid from the Relief Fund of the American Nurses Association, 54 per cent have tuberculosis, these cases falling largely among the younger women from 21-30 years of age.

The remedy suggested is:

First, the recognition on the part of everybody connected with nurses' training that tuberculosis among them is a very real and ever present problem. Second, a very careful physical examination of all applicants for training, with X-ray or fluoroscope readings and a tuberculin test; repeated thorough examinations at regular intervals, preferably every six months. Third, a regulation of the hours of work so that each trainee should have sufficient time for recreation and rest. Fourth, provision of recreation facilities and opportunities for physical exercise. Fifth, teaching of the fundamental facts about tuberculosis, its prevention and treatment, to trainees, and the encouragement of a desire on their part for positive health.

Everyone interested in training schools for nurses would do well to read and ponder on Miss Whitney's article.—Jessamine S. Whitney, *Tuberculosis among Young Women with Special Reference to Tuberculosis among Nurses*, *Am. J. Nurs.*, 28, 8: 766 (Aug.), 1928.
K. F.

Iceland and Its Nursing Service—The real organization of public health work in Iceland may be traced to the efforts of Bjarni Pálsson, the first recognized medical man in Iceland. He studied in Denmark and was appointed by the government in 1760 as their representative for medical affairs. One of his chief duties was to teach the public

elementary hygiene. He also trained young men to help him in his medical work and instructed, supervised, and advised the women who practiced midwifery.

The fight against leprosy is responsible for the beginning of nursing work in Iceland. In 1897, the Danish Free Masons built a hospital for lepers in Iceland. One condition in the gift of deed was that the hospital should employ a Danish trained nurse. The act meant the dawning of nursing in Iceland. As time went on, an increasing number of young women went to Denmark for their training. But for a long time, the word "nurse" meant to the Icelander the Danish trained nurse at the leper hospital.

The increasing communication facilities slowly woke Iceland to its health needs. Now there are 47 district medical officers holding their appointments under the Chief Medical Officer at Reykjavik, the capital. A mental hospital, two tuberculosis sanatoria, and several general hospitals have been built. A state hospital is now being constructed, which will be connected with schools for the medical, nursing, and midwifery professions in Iceland.

There are two Visiting Nurse Associations at the capital, which provide nurses for visiting and hourly nursing and for private duty.

In the year 1920, the Icelandic Nursing Association was formed, made up of Icelandic nurses and some Danish colleagues living in Iceland. There were 12 members. At the present time the organization has 37 active members and 23 associate members, the latter group being made up of student nurses.—From an abstract of Iceland and Its Nursing Service, *Pub. Health Nurse*, 20, 9: 479 (Sept.), 1928.

EDITOR'S NOTE: We can picture better the problems confronting a health worker in Iceland when we recall that it is a mountainous island of some 39,700

square miles, of which only about 2,800 square miles are meadowland. The interior of the island is made up of uninhabitable volcanoes, lava fields, and glaciers. The population of about 91,900 is widely scattered through the mountains for the most part. The mean temperature in February is 27° and in July 54°.

Indian Nursing Service—The 350,000 American Indians existing in this country constitute a Federal Group which offers many difficult health problems not controllable by state health services.

Aside from the ordinary problems of nutrition, housing, quarantine, and isolation, are those of dealing with extreme sparsity of population, differences in type of country, and the varied superstitions of each tribe.

Recently the Indian Bureau has been discouraging the nomadic habits of the Indians by granting individual property rights, encouraging the building of permanent dwellings and supplying field workers to instruct these people in sanitation and hygienic living.

In the last few years adult education has been carried on through encouraging better management of agricultural opportunities, farming and stock-raising with the men, cooking and food preserving with women. Children have been organized into clubs to compete in the same sort of projects.

The field work of the Indian Nursing Service has been organized only since 1924, and has rightly been termed a pioneer service, since it deals with a new service among primitive superstitious people in a sparsely settled country, having only poor roads. At present most of the maternity and infant work is being done with the adult population, but the problem is also being approached in schools along with the other forms of health teaching.

The main disease problems of tra-

choma and tuberculosis are being handled by traveling specialists, and by hospitals located on each reservation. Sanatorium treatment is given for early cases of tuberculosis, and before long diagnostic clinics will be established for the detection of cases in the very early stages of the disease.

In rendering this service, the federal government is not only aiding the Indian to approach the status of his white neighbor, but it is also contributing toward the solution of state problems of rural health.—Elinor Gregg, Nursing Service to the North American Indian, *International Council of Nurses*, 3, 2: 137 (Apr.), 1928. C. F. E.

Strength in Unity—Public health nursing services in Ohio have proved again the value of unity for increased efficiency of service.

Of the 828 public health nurses employed in this state, 138 find their work in the rural districts, 69 of the 88 counties having county nursing service. To prevent duplication of service and to decrease the amount of time spent in travel, every effort is made by private agencies to strengthen official health machinery. While many of these nurses are employed by county boards of health, it is not an uncommon event to have a nurse employed jointly by the county board of health, the board of education, the county commissioner, and a private agency.

Of the 690 public health nurses serving the urban population, 251 are financed by 38 city boards of health; 78 by boards of health and private agencies jointly; 116 by 47 boards of education; and 245 by 63 private agencies.

Light instead of Darkness—Most of us have experienced the darkness which used to be imposed upon those

children who had that popular disease of childhood, the measles. Now, modern teaching is coming to the rescue of the future victims of the disease. Fresh air and good light are necessary in measles. If these are absent, a favorable condition for the growth of undesirable germs is created, for many germs grow best in darkness or semi-darkness.

However, the eyes deserve consideration. Little pledgets of cotton, dipped in cool water, placed for a few minutes on the inflamed eyes in the early stages of the disease, are comforting. If pus is present, very careful cleansing is advised. The eyes may be protected further by turning the head of the bed toward the window. If the light is still too intense, a simple eye shade worn on the forehead may be used to soften it.

Measles is not a cause of crossed eyes. If, during or after any illness, the eyes are used incorrectly (at too close range and for long periods of time) while the muscles are soft, they may become crossed.—B. Franklin Royer, M.D., *Don't Keep Them in the Dark, Hygeia*, 6, 7: 497-499 (Sept.), 1928.

Calendar for 1929—The National League of Nursing Education has just published the 1929 calendar which contains reproductions of historic hospitals of Europe. A picture of the St. Jean Hospital in Bruges appears on the cover of the calendar, reproduced in beautiful soft colorings. With each picture is a brief historical description. A picturesque map is included.

Orders may be sent to headquarters—370 Seventh Avenue, New York, N. Y. The calendar is sold for the benefit of the work of the League and is widely used as a Christmas gift. It costs \$1.00, or if ordered in lots of 50 or more—75 cents apiece.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

CONVENTIONS

"Publicity Clinic—A School for Advertising," was a feature of the Mississippi Valley Conference of Tuberculosis. "Samples of material and actual speeches were dissected by the audience." Conducted by two university professors.

At the same meeting Marguerite Breen, Minnesota Public Health Assn., presented "Viewing Our Publicity Work with an Analytical Eye."

Topics and suggestions for convention programs will be supplied by the Public Health Education Section. The section is ready to plan or to conduct education-publicity institutes, where adequate interest is assured.

As a matter of record it is good to note the following array of topics on health education and publicity at the Chicago meeting of the A. P. H. A.: How to Use Effectively Civic Groups in Promoting Health Programs (General Session); A County Wide Screening Campaign (Public Health Engineering); How Employee Magazines Can Be Used to Promote Health (Industrial Hygiene); Health Education in an Industrial Plant (Industrial Hygiene); What We Should Strive for in Food Advertising (Food, Drugs and Nutrition); Dental Hygiene session (Child Hygiene), and Health Education Division, American Child Health Association, devoted to classroom education; Sex Education, One-day Institute conducted by Illinois Social Hygiene Association; and the various sessions of Public Health Education Section. Moral: "I will

make a special effort to attend the 1929 convention, and I will try to interest at least one other health worker to do likewise."

SLIDES AND FILM SLIDES

"One of the latest devices for visualizing health is the film strip or film slide. This is a series of pictures printed together on a strip of film instead of on individual glass slides. There are several projectors on the market for showing film strips. They can also be used in an ordinary stereopticon machine with a special attachment."

The Metropolitan Life Insurance Company now has available for free distribution the following film strips:

"How to Live Long," "No More Diphtheria," "One Scar or Many?" "Pasteur" (especially for junior and senior high schools), and "Working for Dear Life."

A new "still" film showing the various affections of the heart has just been made available through the generosity of Dr. Emanuel Libman to the American Heart Association. It represents a collection of pathologic specimens secured over a period of about twenty years by Dr. Libman and his associate, Dr. Benjamin Sacks. The captions are sufficiently explanatory and the film should appeal to physicians interested in the pathology of the various types of heart disease. It is not for popular education, but for medical societies primarily.

THE POST OFFICE

Careful study of the new postal regulations may reveal opportunities for saving money—or new helps in making

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

use of the mails. Because of the many new practices and the possibilities of varying local interpretations, always consult the local post office before making use of the new regulations. And send your questions to the editor.

MOTION PICTURES

Health Films and Minute Movies, Metropolitan Life Insurance Co., New York, N. Y., or Ottawa, Can. Descriptive catalog of motion pictures and film strips.

Overweight is no laughing matter; it is a serious health menace. This, in a sentence, is the theme of the new moving picture "Too Many Pounds," released by the Metropolitan Life Insurance Company. The picture shows how present-day lack of exercise, and the ease of living made possible by machinery, have helped to create a very general problem of overweight. This fact is made vivid by a series of contrasting pictures showing the difference between pioneer days and the present. Having stated the problem, the picture shows what one can do about "too many pounds" through exercise and diet under the doctor's direction.

A folder, "What Do the Scales Tell You?" is a collection of weight-for-height tables. This is suitable for distribution at a showing of "Too Many Pounds." To those individuals who are particularly interested in the subject, the Metropolitan Life Insurance Co. can supply their regular pamphlet on "Overweight." Picture free of charge except for transportation expenses.

"See a Movie and Live Longer," by Kathleen Crowley. *Survey*, 112 East 19th St., New York, N. Y., June 15, 1928. 25 cents. The Waterbury Girls' Club gives health movies to the community.

A new one-reel film entitled "The Best-Fed Baby" has been issued by the Children's Bureau, U. S. Department of Labor, Washington, D. C. Its purpose is to advise mothers against the practice of early weaning. The story is about two children, Jack and Jill, and

their young mothers. It shows that a mother's ability to nurse her baby is a matter that lies largely in her own hands, and that much unnecessary weaning can be prevented by simple and natural care.

"Beware the Pitfalls"—an 8-minute animated cartoon statistical picture directed by Iago Galdston, M.D. Detailed synopsis in reprint from *Long Island Medical Journal*. Free of New York Tuberculosis and Health Assn., 244 Madison Ave., New York, N. Y.

EXHIBITS

Why not a window or empty store-room display of fresh air devices? Consult architects, hardware dealers and others to locate practicable devices for windows. Search for home-made expedients. This seems to provide an opening to enlist a committee of architects and others. After this exhibit has opened the subject the committee may be interested in going further into it in preparing for a more elaborate display in the future.

"Window Dressing for Health," by Mary L. Gardner. *Survey*, 112 East 19th St., New York, N. Y., June 15, 1928. 25 cents. The Eastchester Neighborhood Assn. does store window propaganda.

"Will you please send me information concerning exhibits, especially any publications you may have."—From a state college of agriculture specialist in nutrition. What kind of exhibits for what purpose at what time and where and at what cost—what *would* you try to tell this specialist?

EDUCATIONAL MATERIAL

Cancer. 16 p. pamphlet. John Hancock Mutual Life Ins. Co., Boston, Mass. Prepared in coöperation with American Society for Control of Cancer. Free.

Malaria. 8 p. pamphlet with illus.

Metropolitan Life Ins. Co., New York, N. Y. *Free*.

A series of pamphlets on "the teeth and their care prepared for the information of the public." Educational Dept., American Dental Assn., 58 East Washington St., Chicago, Ill.

A group of posters and posterettes (stickers) "intended for use in classrooms, the posterettes serving as a supplementary educational instrument to be used in routine classroom work, such as composition, free-hand drawing, home economics, and hygiene." By New York Tuberculosis and Health Assn. Distributed by National Tuberculosis Assn. Open windows, clean mouth and body, milk and vegetables, etc. White silhouettes on red. Well done.

CONTESTS

After one has struggled with wording a diphtheria poster to make it scientifically accurate, popular and action-compelling—what can he say about turning loose a lot of high school art students to concoct phrases on posters that will satisfy the public health specialists? One way out is to submit as a part of the contest material a selection of phrases stating the scientific facts. (More contest suggestions to follow this.)

A contest to emphasize the various ways of putting milk in the diet is being promoted by the Evaporated Milk Assn., 231 South La Salle St., Chicago, Ill. Particulars upon request. The University of Chicago, Good House-keeping Institute, and the American Child Health Assn. are represented on the jury which will award the \$10,000 in prizes.

"Posterizing Diphtheria Prevention," in *The Poster*, Chicago, Ill. (Aug., 1928). An illustrated account of the New York poster contest.

A "State Diphtheria Poster Contest Number," *S. C. A. A. News* (105 East 22d St., New York, N. Y.), reproduces

20 of the posters in black and white. *Free*. 1,000 copies for \$9.00.

A book store, according to *Publishers' Weekly*, aroused much interest through offering a prize for the oldest and most valuable book owned in the community. Try a contest for the oldest "health book" or pamphlet. Phrase the offer to bring out the "home doctor books." When the award is announced give out the report of a committee on the general good and bad features of the entries. Display a selection of the old books in contrast with some new and accepted books and pamphlets in a book store window.

In the prize playwriting contests for high school students, Atlanta, Ga., won first and third place, the second prize going to Fall River, Mass. Details in *Bulletin*, National Tuberculosis Assn., 370 Seventh Ave., New York, N. Y., Aug., 1928.

Nearly 7,000 spectators at city-wide first aid competition in Chicago. See *Red Cross Courier*, Washington, July 2, 1928.

Three prize stories in the contest conducted by the *Public Health Nurse* were published in the March, April and May issues of that magazine.

For results of the state diphtheria poster contest see *S. C. A. A. News*, 105 East 22d St., New York, N. Y., July, 1928. *Free*.

HONORABLE MENTION

To East Harlem Nursing and Health Demonstration (354 East 116th St., New York, N. Y.): For the Maternity Service Report—with table of contents and easy to find facts (date, price, cover page, one-sentence summary of scope of the report).

To American Public Health Assn.: For an *Appraisal of Public Health Activities in Cincinnati, Ohio*—with a title page including well-arranged material desirable in a survey report, and a detailed table of contents.

SLOGANS AND PHRASES

"According to all the signs, September is a good month in which to be careful."—*The Anode*, Butte, Mont.

"Better Children for our Nation—A Better Nation for our Children"—Cover page of *The Story of May Day*.

"Syracuse Wishes You Well"—*Better Health*, Syracuse, N. Y.

"Too Many and Too Young"—*Racine Weekly Health Review*. Too many early deaths.

"It is not the Babies Born, but the Babies Saved that count."—Ill. State Tuberculosis Assn.

"Accidents do not happen—they are caused."—*The Foreman*, Wausau, Wis.

REQUESTS

Who publishes a small 4-page folder entitled Sun Baths (for small children)? And why, please, is no publisher given?

A Texas county public health committee wanted "suggestions on how to make posters." They were referred to The Amateur Poster Maker (Pilgrim Press, Boston, Mass. \$1.00) and to Posters and Poster Making (Student Volunteer Movement, 25 Madison Ave., New York, N. Y. 25 cents). Any other suggestions?

Wanted: Photographs showing scales being used by staff or citizens.

Wanted: Photographs of many types of health service—by several book publishers. A chance to serve and gain fame. What have you? Have they been used anywhere?

BULLETINS

An attractively illustrated envelope is used for the *Health Bulletin* of the Health Conservation Assn., Hall Bldg., Kansas City, Mo. Sample free.

If you mail marked copies of your bulletin or house organ to persons and agencies mentioned in it in any fashion

you may strengthen friendships. Even those who are on the mailing list may overlook the item if not marked—and some of your readers will appreciate having an extra copy.

For a list of humorous cuts for multi-graphed or printed bulletins write "171" on your business card, or on a 3 x 5 card, with your full address—and send to the editor.

Bulletin, St. Louis Health Dept., May, 1928, is a social hygiene number, prepared by the Missouri Social Hygiene Assn. It contains some interesting copy, and is a good example of co-operation between official and unofficial agencies.

"Some Human Interest Stories" is a new heading in *Monthly Bulletin*, Indiana State Board of Health. Visiting nurses are contributing the stories.

REGRETTABLE—BUT TRUE

The annual report of a state tuberculosis association: Rather good cover page; then a blank page; then comes "Report of Executive Office." Why should anyone except the executive secretary and some of the board members care to read a "report of the executive office"? Much the same material would stand a better chance of getting a reading if that report could be labelled to suggest a real common interest.

Thanks for "Attention Calling"—Many of the best bits for this department are not reported by the health department or health association responsible for them—but happily several of our readers recognize the common right to the good idea wherever it may sprout. Two of the most consistent "attention callers" are Ray H. Everett and James A. Tobey. We thank you! And hope for more of your kind.

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

The Next Step in Public Health— Sanitarians have long been agreed that one of the necessary next steps in public health progress is the more effective co-ordination of federal health activities. Louis I. Harris, M.D., as chairman of the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association, discussed the matter in an able manner last June in his chairman's address, which has been printed in the *Journal of the American Medical Association* for August 25, 1928.

"Federal legislation is needed to establish an independent federal department to guide and coördinate public health activities, be they of an administrative or of a research character," writes Dr. Harris, and he properly points that "This is long overdue." He suggests that, without invading state rights, such a federal department might establish standards in public health, analogous to the service of the U. S. Bureau of Standards. Among standards which he mentions as possible are those pertaining to budgets for official health work, qualifications for those who practice public health, and tenure of office. He says:

When economy seems to be so large a claim to distinction of the arbiters of our national affairs, it is amazing that the bureaus, divisions and laboratories having health functions dispersed among the various departments of the federal government have not been united for the sake of economy of money and effort and of the strength that makes for unity.

It is, indeed, amazing.

A much less definite scheme is advocated by Dr. C. L. Ferguson writing on "Health in Industry" in the *Journal of the A. M. A.* for September 22, 1928.

He writes: "To have a health program function for the public as it does for the workers in a well organized industry would require national, state and local organizations." The author is evidently oblivious of the fact that these already exist. "The President of the United States would be responsible for the national health," he continues; "this responsibility would be delegated down through the states to the various physicians in each community or county."

When the 71st Congress convenes in December, it is to be hoped that practical legislation for federal health correlation will be considered, as it was in the 70th Congress, and that if passed, as it also was, there will be a broad-minded President who will approve the measure, and not veto it; as unfortunately happened.

School Medical Inspection Laws—

Forty-two states now have school medical inspection laws of some kind, according to the September, 1928, number of *School Life* of the U. S. Bureau of Education, in the Division of School Hygiene of which James F. Rogers, M.D., is director. In 16 states medical examination is mandatory for pupils in all school districts. Examinations are given in 23 states by specially trained persons—physicians or nurses, physical directors, dentists, or some combination of these. In 13 states examinations may be given by the teacher; in 2 states by the superintendent, principal or teacher.

Going Too Far—A milk ordinance of the City of Bartow, Fla., which imposed a charge of \$25 a day for an in-

spection of dairies more than five miles beyond the city limits, and no such extortion against dairies nearer the city, has very properly been held unreasonable and void by the Supreme Court of Florida, *Root v. Mizel*, 117 So. 380.

Tuberculin Test Upheld—In at least a dozen states the courts of last resort have sustained laws requiring the tuberculin testing of cattle. These decisions have been handed down in Iowa, Kentucky, Louisiana, Maryland, Minnesota, Mississippi, Missouri, Nebraska, New Jersey, New York, Tennessee and Wisconsin. In a recent and able opinion, the Court of Appeals of New York has affirmed a decision of the Appellate Division of the New York Supreme Court upholding the tuberculin testing law of that state. *People v. Teuscher*, 248 N. Y. 454.

In New York the Agriculture and Markets Law states, among other things, that whenever 90 per cent of the cattle in any town have been subjected to the tuberculin test and the owner of any untested herd refuses or neglects to have his herd tested, the Commissioner of Farms and Markets may order his farm quarantined, so that no animal and no product may be removed from it. Such an order was issued against Teuscher, a farmer of Rome Township. He refused to obey and assailed the statute as an unconstitutional interference with liberty and property and a denial of the equal protection of the laws.

The court held, however, that the statute was valid and that the area plan violated no constitutional requirements. "Legislation is not void because it hits the evil that is uppermost," said the court. "Equally it is not void because it hits the evil that is nearest." It was also pointed out that similar legislation exists in Iowa, Minnesota, New Jersey, Vermont, Massachusetts, California, Illinois, Idaho, Indiana, Missouri, Wisconsin, Ohio, Tennessee, and Washington,

and that "an evil prevalent far and wide has evoked far and wide the reaction of a like response."

The command of the executive charged with enforcing this New York law was held to be neither a denial of equal laws nor an illegitimate delegation of legislative power. A notable statement in the opinion is the following:

Small use would there be in stimulating the many within a township to a care of the public health, if one or a few wisecracks or obstructionists could make the labor vain. More and more, in its social engineering, the law is looking to coöperative effort by those within an industry as a force for social good. . . . We see this in the very statutes, already quoted, with their attempt to check tuberculosis by coöperative effort.

Septic Tank as a Nuisance—A person can maintain a suit against a city for having a septic tank in operation near her residence, but to recover damages it must be alleged and proved that the plaintiff suffered special injuries different from those suffered by the public generally, according to a recent Missouri decision, *Newman v. City of Marceline*, 6 S. W. (2d) 659.

In Texas the erection of a slaughterhouse was enjoined on the ground that a nuisance would be created. *Huff v. Letsinger et al.*, 7 S. W. (2d) 181.

Physical Examinations for Occupational Diseases—In 5 states laws require monthly physical examinations of certain industrial employes, according to an item in the *Monthly Labor Review* of the U. S. Department of Labor for September, 1928. The Ohio, Pennsylvania, and New Jersey acts are said to be aimed chiefly at the lead hazard, while the Illinois and Missouri laws "cover a great number of diseases."

In 15 states there are laws which make it the duty of retained physicians having knowledge of persons believed to be suffering from certain occupational diseases contracted in employment to report them to departments of health or

labor. The states having such laws are said to be: Connecticut, Illinois, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, New Hampshire, New Jersey, New York, Ohio, Pennsylvania, Rhode Island and Wisconsin.

The Quinine Monopoly—Of importance to public health and medical science is the announcement of the U. S. Department of Justice, dated September 20, that a consent decree had been entered by the Federal District Court in New York, permanently enjoining further violations of the anti-trust laws by foreign interests who control the world's supply of quinine. This action followed the seizure by the government of about \$100,000 worth of quinine in warehouses in New York.

Ninety per cent of the world's quinine originates in Java in the Dutch East Indies, and a syndicate of Dutch, German, French, English, and American manufacturers has absolutely controlled production, distribution and prices. This monopoly has been "about as effective as there is anywhere," according to the U. S. Department of Commerce, which has coöperated in teaching this syndicate a lesson.

By the terms of the decree all manufacturers of quinine will henceforth be restrained from:

1. Imposing restrictions on the resale of quinine in the United States.
2. Hindering the shipment in, into, or from the United States of cinchona bark or quinine derivatives.
3. Participating in any arrangement for pool-

ing or division of profits or territory with reference to sales made within the United States.

4. Discriminating between purchasers located within the United States.

5. Selling on the condition that the purchaser will not deal with a competitor of the seller.

Miscellaneous Items—The Indiana decision requiring a city to pay damages for stream pollution, *City of Frankfort v. Slipper*, which was discussed in the September JOURNAL, may be found in Volume 162, *Northeastern Reporter*, page 241.

A bulletin on Mosquito Remedies and Preventives (*Farmers Bulletin No. 1570*) has been issued by the U. S. Department of Agriculture. On September 20, 1928, the Bureau of Entomology of this department gave out a statement that Paris green is valuable to dust pools of water where mosquitoes breed and thus prevent the breeding. It works especially well in the case of the anopheles, say Drs. L. O. Howard and F. C. Bishopp of the bureau.

Reindeer meat is extolled in a statement from the U. S. Department of the Interior, issued on September 21, 1928. This meat is said to be highly nutritious.

Still another department of the federal government has recently given out information of a health character. The Bureau of Standards tells us that batiste or nainsook cotton, linen, and certain kinds of rayon are more transparent to ultra-violet rays than are pure silk or wool. This may have a practical application in the clothing of children.

because of limitations of space and of pertinacy, and of relative completeness of the available information, the subject matter is restricted to mammalian cells, historical discussions are largely excluded, and the developmental and embryological phases minimized.

Although the title expressly states that the scope of the work is the cell "in health and disease," there is a disappointingly small amount of information on the pathological phases of the various cellular types treated in the 37 chapters of the work.

The editor and his collaborators are to be congratulated on the uniformly high order of excellence, the well balanced proportions in the treatment of the various parts, and the scholarly thoroughness which combine to give a unity to the ensemble. The illustrations are less well coördinated.

Cowdry's *Special Cytology* is a companion work to the *General Cytology*, prepared by a comparable group of collaborators. This later work will appeal to a larger group of persons, especially to students of medicine. It is indispensable to every student of histology and all students and investigators in most fields of biology will find it invaluable as an authoritative work of reference. CHARLES A. KOFROID

Dictionary of American Medical Biography—By Howard A. Kelly, M.D., LL.D., and Walter L. Burrage, M.D. New York: Appleton, 1928. 1,364 pp. Price, \$12.00.

This is essentially the second edition of *American Medical Biographies*, and will be welcomed by all interested in history as well as in medicine. There are 2,049 biographies given, some 300 of which are new, certain others having been removed, leaving a total of 101 sketches over the previous volume. The men selected for notice are apparently wisely chosen, and on the whole the book is remarkably accurate,

though certain errors have crept in which should have been corrected.

The writer believes that the present generation pays too little attention to those who have brought medicine in the United States to its present high position. Too great honor cannot be paid to the pioneers, who worked under great difficulties and depended upon the training of their senses and observation for facts which are now derived from the laboratory. There are few studies of more importance than the lives of those who have gone before, and contemplation of their attainments will do much to keep the reader in accord with the Apostolic injunction "Not to think more highly of himself than he ought to think."

The authors state that the present volume is the final form of twenty years of labor—"years of delightful occupation." It shows intensive study and much digging into the records of the past. The medical profession particularly owes a debt of gratitude to the authors for their work.

The printing and make-up of the book are excellent. M. P. RAVENEL

Folklore of the Teeth—By Leo Kanner, M.D. New York: Macmillan, 1928. 316 pp. Price, \$4.00.

That modern Hindus look with disgust upon our unsanitary toothbrush, following the undeniably superior practice of daily use of a fresh fibrous twig, is interesting reading just now—in the day of *Mother India*. This is only one item of 300-odd pages of interesting reading, a fascinating jumble of folklore and history relating to all things dental thrown together kaleidoscopically by Dr. Leo Kanner, of the Yankton State Hospital, Yankton, S. D.

Tracing dental custom through the maze of historic and present-day tribal reference leads us surprisingly far back and far afield. Through these sketchy references gleaned from a vast read-

ing, one sees in the superstitious and religious practices of present-day primitive peoples glimpses of similar beginnings scattered along historical chronology.

That "cleanliness is next to godliness" is by no means a modern conception—"You shall clean your mouths, for this is a means of praising God," was the dictum of the Prophet, set down in a compilation of Mohammedan writers in 900 A.D. Before that (in 632 A.D.), Abu the Truthful said, "My father told me (he knew it from Ibn Abi Shaiba, he from Abd Allah b. Idris, he from Muhammed b. Ishaq, he from Abd Allah b. Abi Bekr, he from Omar, he from Aisha, Muhammed's favorite wife) that the Prophet said this: 'The siwak is an implement for the cleansing of teeth and a pleasure to God.'"

We learn that artificial dentures were common in Talmudic times and came by way of the Greeks and Etruscans to Rome at the time of the Emperors, but all as a means of feminine adornment. He quotes from Martial who says of one of the Roman ladies: "Laicania has white teeth, Thais brown. How comes it? One has false teeth, one her own."

It is interesting to read that the tooth pick along with the ear spoon and head scratcher and other toilet articles has been frequently found by archeologists in ancient graves.

Also, care of the removal of food from the teeth after eating is so early and so widespread a custom that its survival would seem to indicate a hygienic value, although the writer's assumption of causal relationship between the dirtiness of the teeth of certain South African and South American tribes and their carious condition leaves out of consideration his own implication of dietary deficiency in the statement that "their food consists principally of flour." Again, the discussion of mastic,

betel and gambir is concluded by the somewhat questionable statement, "all this must prevent the development of caries." While it is clear, in reading the book, that the writer assumes that the reader will read from his own background of information, this is the only caution to be sounded in connection with the use of this delightful book, that it is literature and folklore—not intended by the author to be in any degree a treatise on modern dental science.

The book will be of interest to a great variety of readers—the dentist, to trace the development of modern dentistry; the student of social science who finds in many of the customs described interest more fundamental than dental; and the teacher in high school or college who is hard put to it to find something to give the saving touch of humor to his classroom lecture on a very resistant subject. MAUD A. BROWN

A Short Manual of Industrial Hygiene—By Leonard P. Lockhart.
London: John Murray, 1927. 114 pp. Price, \$1.00.

The chief aim of this small volume, according to its author, is to interest industrial supervisors in the general problems of industrial health, and to show how in these matters the interests of both employers and employes are inextricably interwoven. To one experienced in the field of industrial hygiene the need for such a book as the present one is evident. Factory managers, foremen and supervisors continually ask questions concerning industrial hygiene which are answered by this small volume. In all comprising 7 chapters and of slightly over 100 pages, this volume deals with questions of ventilation, illumination, washing facilities, personal hygiene, common communicable diseases, accidents, fatigue, seating, and a discussion of adolescence and the youthful employe. The reader of this book

must bear in mind the intent of the author. The factory supervisor and official will do well to have copies of this book available for the use of foremen and overseers.

LEONARD GREENBURG

Mouth Hygiene—By *Alfred C. Fones, D.D.S. (3d ed., rev.) Philadelphia: Lea & Febiger, 1927. 348 pp. Price, \$5.00.*

This is a textbook for dental hygienists. It gives in clear and simple language an excellent picture of the anatomy of the various parts of the head, including the circulation and nerve supply. It has a long chapter on malocclusion, and stresses, perhaps unduly, its relation to dental disease. It outlines clearly and in great detail the work and duties of the dental hygienist in the practice of her profession.

In discussing the subjects of deposits and accretions on the teeth, pyorrhea alveolaris and dental caries, great emphasis is placed on the influence of external causes in distinction from physiological causes. It is apparently the unanimous opinion of the authors who contribute to the text that mechanical irritation resulting from deposits on the teeth, the chemistry of the saliva, and lack of mouth cleanliness are the major factors in causing dental decay and infections relating to the teeth. In some respects the book seems to be a defense for that theory; at any rate it gives much more space and lays greater emphasis on the mechanical than on the physiological phases of this problem. One of the authors in speaking of dental caries and pyorrhea states: "The first of these can be reduced appreciably by oral hygiene; the second can be almost entirely prevented by the same method."

Comparatively little is said about the importance of early filling of small cavities and developmental pits and fissures in early child life. One chapter is de-

voted to the subject of foods and another to the history of the dental hygienist movement. The technic of "Prophylactic Treatments" is given in lengthy and minute detail.

The book gives in a very clear manner the views of the authors on the subject of dental hygiene. It fails, however, to give a comprehensive and well balanced picture of the present status of the mouth hygiene movement. The student who studies this text is liable to become prejudiced in his views and practices in the field.

WILLIAM DE KLEINE

Bacteriology for Nurses—By *Charles F. Carter, M.D. St. Louis: Mosby, 1928. 213 pp. Price, \$2.25.*

This book gives a clear exposition of the science of bacteriology and its various applications to medicine. The practical side is emphasized throughout. There are a number of illustrations, most of which are good, but some very poor. Each chapter ends with "Questions for Review."

We know of no more practical book for the use of nurses than this. The printing and make-up are good.

M. P. RAVENEL

Syphilis, A Treatise on Etiology, Pathology, Symptomatology, Diagnosis, Prognosis, Prophylaxis, and Treatment—By *Henry H. Hazen, M.D. (2d ed.) St. Louis: Mosby, 1928. 643 pp. Price, \$10.00.*

The first edition of this book was favorably received. The present work has been entirely revised and partly rewritten. The bibliography has been brought up to date. The illustrations are plentiful and good.

The printing and make-up of the book are excellent, though we wish that a lighter paper had been used. It will doubtless hold its place as a standard text on this most important subject.

M. P. RAVENEL

Diabetic Manual for Patients—*By Henry J. John, M.D., F.A.C.P., Maj. M.R.C. St. Louis: Mosby, 1928. 202 pp. Price, \$2.00.*

This book is written for the guidance of persons suffering from diabetes. It gives simple explanations of the cause of the disease and directions for treatment. The care of medical supervision throughout is emphasized.

Appendices give charts of foods with their relative values in carbohydrates, proteins and fats, and suitable diets and recipes. It is non-technical and can be recommended for the purpose for which it is written.

M. P. RAVENEL

The Opium Problem—*By Charles E. Terry, M.D., and Mildred Pellens, for the Committee on Drug Addictions in collaboration with The Bureau of Social Hygiene, Inc. New York, 1928. 1042 pp. Price, \$5.00.*

Even the alcohol problem has not led to more heated or prolonged controversies than the matter of drug addictions. In 1921, the Committee on Drug Addictions was formed, with Katharine Bement Davis as Chairman, Charles E. Terry, M.D., Executive, and Mildred Pellens, Associate Executive.

The first task was to determine the actual conditions. This involved an enormous amount of work, including correspondence and study of literature. In 1925 the material collected was put into form as a report to the committee, and for the first time there was brought into one volume a compilation of the views of many authorities as well as abstracts of current literature on the subject. The present volume contains the substance of this report, with some condensation. Though the study has been confined to the chronic use of opium and its derivatives, it contains much information about other habit

forming drugs, the laws concerning them, methods of distribution, etc.

The work shows conscientious study, expert compilation and sound judgment, in addition to which its arrangement and wording make it easily available not only to the expert student, but to the social worker or layman who desires information on this most important subject.

There are 9 appendices, 3 of which give the agreements signed at Geneva in 1912 and 1925; others give national and state laws, and the last a digest of editorial literature on the Harrison Act. A well selected bibliography and good index close the volume.

One is tempted to discuss many points, but the *Résumé* by the authors gives an excellent summary which all who have studied the question can accept. There is need of further study and exact experimentation, and until facts can be established, dogmatic statements and half-baked regulatory laws can only lead to injustice, and further confuse a situation which in many respects is far from clear.

It can be said without hesitation that it is the most important contribution to the problem extant, and it can be commended to all classes of readers. The make-up of the book is good.

M. P. RAVENEL

Growing Up—*By Karl de Schweinitz. New York: Macmillan Co., 1928. 104 pp. Price, \$1.75.*

Parents and teachers who are searching for a book that presents the facts of reproduction comprehensible to children between 6 and 12 years of age will find this helpful. The story is told in a simple, straightforward way and the illustrations have been selected with discrimination as well as from the art viewpoint.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

The Question of Vaccination—Excellent editorial comment on the Report of the Committee on Vaccination (Great Britain) which presents positive answers to questions about the relative dangers of vaccinia and mild smallpox, and the possibility of encephalitis following vaccination.

ANON. The Committee on Vaccination. Med. Off., 40: 9 (Sept.), 1928.

Medical Guidance—A valuable presentation of the need of public medical guidance, suggesting the extension of the plan of the Kings County Medical Society. Inquirers are referred to appropriate lists of member general practitioners or specialists.

ARMSTRONG, D. B. Organized Medicine and Individual Health and Medical Guidance. J. A. M. A., 91: 9 (Sept. 1), 1928.

Chromium Plating Hazards—All but 2 of 23 workers in chromium plating plants whose occupational history was known showed some inflammation of the nasal tissue, but no damage to the remainder of the respiratory tract was evident.

BLOOMFIELD, J. J., and BLUM, W. Health Hazards in Chromium Plating. Pub. Health Rep., 43: 36 (Sept. 7), 1928.

Antiseptic Efficiency of Sprays—The record of experiments indicating that antiseptic sprays exert a bactericidal effect upon *B. coli* suspended in air.

DOUGLAS, S. R., et al. Effect of Antiseptic Sprays on the Bacterial Content of Air. J. Indust. Hyg., 10: 7 (Sept.), 1928.

Age Distribution of Children's Diseases—Density of population affects the age distribution of children's diseases. The risk of attack is in the

early ages in cities and in the later age groups in rural communities.

FALES, W. T. The Age Distribution of Whooping Cough, Measles, Chickenpox, Scarlet Fever and Diphtheria in Various Areas of the United States. Am. J. Hyg., 8: 5 (Sept.), 1928.

Lessening the Benzol Hazard—A survey indicating a marked decrease in the use of benzol in industry. Substitutes are rapidly being utilized.

HAMILTON, A. The Lessening Menace of Benzol Poisoning in American Industry. J. Indust. Hyg., 10: 7 (Sept.), 1928.

Malta Fever—In addition to the drinking of infected milk, the handling of diseased animal carcasses appears to be a not unusual source of infection with undulant or Malta fever.

HARDY, A. V. The Epidemiology of Undulant (Malta) Fever in Iowa. Pub. Health Rep., 43: 38 (Sept. 21), 1928.

Rickets Preventives—Clinical studies are reported which indicate that irradiated ergosterol is the most potent antirachitic agent.

HESS, A. F., and LEWIS, J. M. Clinical Experience with Irradiated Ergosterol. J. A. M. A., 91: 11 (Sept. 15), 1928.

Causes of Tooth Decay—A study of two groups of children with good and bad teeth in which the most significant difference was the diet. Heredity, infectious diseases, and care of the teeth appeared to have little if any effect.

KAPPES, L. O. Factors in the Decay of Teeth. Am. J. Dis. Child., 36: 2 (Aug.), 1928.

The Health Officer's Value—The health officer not only saves the public from contagion, but promotes hygienic habits. His preventive medical activi-

ties do not interfere with curative medicine but tend to make people live to need treatment during a longer life.

KNIGHT, I. W. What is the Value of the Health Officer? *J. M. Soc. New Jersey*, 25: 9 (Sept.), 1928.

Calcium Assimilation—Children fed raw milk maintained a better calcium balance than when on pasteurized, evaporated or dried milk. No noticeable difference was observed in adults.

KRAMER, M. M., *et al.* A Comparison of Raw, Pasteurized, Evaporated, and Dried Milk as Sources of Calcium and Phosphorus for the Human Subject. *J. Biol. Chem.*, 79: 1 (Sept.), 1928.

Typhoid Fever Outbreaks—A detailed account of water-borne typhoid fever outbreaks indicating anew the need for adequate water treatment and the examination of convalescents and food handlers.

KENDALL, C. F. The Epidemiology of Typhoid. *J. A. M. A.*, 91: 11 (Sept. 15), 1928.

Uses of Occupational Therapy—The rehabilitation of the disabled soldier by occupational therapy has been so successful that the same methods should be applied generally to chronically disabled civilian cases.

MOCK, H. E., and ABBEY, M. L. Occupational Therapy. *J. A. M. A.*, 91: 11 (Sept. 15), 1928.

Training Health Officers—The plan of providing practical experience in the field together with a short course of instruction at a University is offered as a practical method of training prospective health officers.

MOUNTIN, J. W. A Plan for Training County Health Officers. *J. A. M. A.*, 91: 10 (Sept. 8), 1928.

Health Supervision—A record of experience in the health supervision of industrial executives, in which the men are found to cooperate, follow hygienic

advice, and correct more than half their defects. The need of exercise in winter is stressed.

MURRAY, H. G. Health Supervision of Executives in Industry. *J. A. M. A.*, 91: 9 (Sept. 1), 1928.

Better Midwifery—A plea for better antenatal care, closer cooperation between midwife and general practitioner, and an earlier admission of abnormal cases to the hospital.

OXLEY, W. H. F. Prophylaxis in Midwifery. *Med. Off.*, 40: 8 (Aug. 25), 1928.

Etiology of Rickets—Two lectures showing that rickets is a disorder of calcium and phosphorus salt metabolism, usually the result of defective absorption from the bowel, due either to deficiency in the supply of the salts or of Vitamin D.

PARSONS, L. G. Some Recent Advances in Our Knowledge of Rickets and Allied Diseases. *Lancet*, 2: 9-10 (Sept. 1-8), 1928.

Significance of Oyster Scores—Although the general tendency of shell oyster scores (bacteriologic) is to increase with the contamination of the water, no fixed ratio can be established. This is one conclusion of an exhaustive study of this important question.

PERRY, C. A. Studies Relative to the Significance of the Present Oyster Score. *Am. J. Hyg.*, 8: 5 (Sept.), 1928.

"Filtrable" Tubercle Bacilli—The authors are of the opinion that there is no such animal and they tell convincingly the reasons for their belief.

PETROFF, S. A., and COOPER, F. B. "Filtrable Forms" of the Tubercle Bacillus. *J. Infect. Dis.*, 43: 3 (Sept.), 1928.

Oyster-Borne Typhoid Fever—A detailed account of the epidemiologic study of a Maryland outbreak of typhoid fever caused by oysters removed from unprotected waters in Virginia.

RAMSEY, G. H., *et al.* An Outbreak of Ty-

phoid Fever and Gastroenteritis Attributed to the Consumption of Raw Oysters. Pub. Health Rep., 43: 37 (Sept. 14), 1928.

Skin Disinfectants—A culture of *Staphylococcus aureus* applied to the skin in concentrations fifty times that found on dirty human skin was followed 24 hours later by applications of mercurochrome and iodine. Under these conditions the aqueous-alcohol-acetone solution of mercurochrome was found equal to iodine in disinfection qualities.

REDDISH, G. F., and DRAKE, W. E. Mercurochrome 220 Soluble and U S P. Tincture of Iodine. J. A. M. A., 91: 10 (Sept. 8), 1928.

School Nursing—A symposium on the purposes and methods of school hygiene in the elementary and secondary grades.

ROOD, E., *et al.* The School Nurse and Health Instruction. Pub. Health Nurse, 20: 9 (Sept.), 1928.

More about Skin Disinfectants—Experiments are reported in which cultures of organisms were smeared on skin followed by various solutions of mercurochrome and iodine. Under the conditions iodine is found superior to mercurochrome in bactericidal action.

SIMMONS, J. S. Bactericidal Action of Mer-

curochrome 220 Soluble and Iodine Solutions in Skin Disinfection. J. A. M. A., 91: 10 (Sept. 8), 1928.

Post-War Paratyphoid—A review of several outbreaks of paratyphoid fever indicating that infections contracted during the war may have been responsible for the carriers who began the epidemics.

THOMPSON, H. H. The Post-War Prevalence of Paratyphoid Fever. Pub. Health, 41: 12 (Sept.), 1928.

Lead Poisoning from Pipes—A study of 90 water supplies conducted through lead pipes was made. Of 253 users of the water, a quarter were found to be poisoned by it. Children and women showed a lower incidence than men.

WRIGHT, W., *et al.* Lead Poisoning from Lead Piped Water Supplies. J. Indust. Hyg., 10: 7 (Sept.), 1928.

Mental Hygiene in Nursing—A paper suggesting psychiatric nursing services in general hospitals, the introduction of methods in nursing education, and the advancement of nursing in mental hospitals.

RUSSELL, W. L. The Place of the Nurse in Mental Hygiene. Am. J. Nurs., 28: 9 (Sept.), 1928.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Montclair, N. J.—“The 1927 Health Audit” of the town of Montclair consists of 39 pages of text and statistical data, printed in readable type on soft paper, and bound in attractive green paper covers. Following the Health Department personnel list is a table of contents, facilitating reference to special phases of the report.

The department records the full co-operation of physicians in efforts to educate the public in preventive health measures. Diphtheria prevention has been vigorously advanced, special attention having been given to preschool children. A group of school children (441) inoculated last year were re-Schicked, and of these, 82 per cent were found to have acquired an immunity. Most of those still susceptible were given a second course of inoculations. Of 721 children given the Schick test for the first time, 29 per cent were found to have natural immunity.

Montclair had an estimated population in 1927 of 34,418, of whom 68.5 per cent were native white, 19.5 per cent foreign white and 12 per cent colored. A general death rate of 10.7, a birth rate of 17.9, and an infant mortality rate of 54.5 were recorded. The report concludes with a list of ordinances passed last year, and recommendations for future development.

Newton, Mass.—The concise report of this city of 56,608 population contains a table of deaths classified by age, by cause, and by months, exclusive of stillbirths, for 1927, a table of deaths under 1 year and births, a summary of food inspections, and a table showing the births, deaths, stillbirths and persons married, with population and rates per 1,000 for the years 1918–27. During April, May and June, clinics were

established by the board for the examination of children proposing to enter school in September, for the purpose of discovering and correcting defects before the children entered school. Two hundred and thirty children were examined, of which 27 were found to have defects needing correction, and 15 of these corrections were made before school opened. In the Health Department a nursing division was established. Five school nurses and 1 tuberculosis nurse are working on a 12 months' basis. The city was divided into 6 districts and a nurse put in charge of each district. The table of food inspections shows a total of 181 dairies inspected in 1927. A total of 330 food inspections were made. The death rate for the year was 9.75, the infant mortality rate 48.84, and the birth rate 15.26.

Malden, Mass.—The organization of the Board of Health included 2 health inspectors, 1 part-time milk inspector, 1 public health nurse, 2 baby welfare nurses, and 1 part-time dentist. The death rate for the year was 9.88. Fifty-two deaths from contagious diseases were reported, 18 of which were from tuberculosis. The report of the Malden Tuberculosis Dispensary shows that 1,692 visits, with 77 new examinations and 217 reexaminations, were made. Four hundred and forty-six children were treated at the Dental Clinic, the total clinic attendance being 1,367. Two hundred and six cases were admitted to the Contagious Hospital, 144 of which were scarlet fever, 28 diphtheria and 10 erysipelas. A law to regulate the manufacture of ice cream and one to regulate the operation and equipment of pasteurizing plants were placed on the statutes. Two hundred and twenty dairies were inspected in 1927 as

against 18 for 1926, with 9 less convictions in 1927 than in 1926, indicating the assumption by the dealers of responsibility for the quality of milk.

Attleboro, Mass.—The annual 1927 report of the Health Department of this city of 20,980 people contains two photographs and numerous tables emphasizing particularly the work of the health camp for undernourished boys. The 40 boys in attendance, who were from 10 to 21 per cent underweight, ranged in age from 8 to 14 years. During the 6 weeks the average gain in weight was 7.86 pounds. The camp program featured intensive posture work, while daily classes in health and the various handicrafts were conducted. Three hundred and twenty-seven cases of communicable diseases were reported in Attleboro in 1927 as against 784 in 1926, the lowered incidence being due in part to the small number of chicken pox, measles, German measles and whooping cough cases occurring. Three cases of infantile paralysis were reported with 1 death, as well as a slight increase in the number of scarlet fever and diphtheria cases. There were 267 deaths in Attleboro during the year. The crude death rate was 12.7, the tuberculosis death rate for residents, 20. A table of estimated appropriations for 1928, a complete table of causes of deaths in 1927 by months, and reports of the Health Department nurse and the Inspector of Milk are included.

Knoxville, Tenn.—The annual statement for 1927 of the Bureau of Health of the Department of Public Welfare appears in mimeograph form and contains 103 pages of carefully prepared text and tabular information indicative of commendable progress. Statistical charts indicate steady decreases in deaths from typhoid and other filth-borne diseases coincident with increased privy sanitation. Nursing visits, increased

volume of laboratory work, and progress in milk and meat supervision are also shown graphically. The infant mortality rate of 76 is the lowest in history for this city, the rate for 1926 being 89. A birth rate of 23.5 and a general death rate (corrected for residence) of 13.05 are noted. A per capita expenditure of 61 cents for health is recorded.

Educational work has been extensive and varied. In addition to the distribution of thousands of health bulletins, pamphlets and letters, it has been a part of the work of the bureau's personnel to conduct several classes from high schools and the University of Tennessee, as well as numerous other individuals, through the health center, in an effort to give them a more intimate knowledge of the operation of such an institution. The bureau also assisted the university in training a class of sanitarians for field work in the state.

During the year, 3,330 food handlers from dairies, cafes, cafeterias, grocery stores, etc., were given physical examinations for the detection of communicable diseases. Specimens for laboratory examinations were a routine requirement.

The organizations having their headquarters in the health center building are the Bureau of Health, the Community Chest, the Red Cross, the Girl Scouts, the Junior League, the Anti-tuberculosis Association, the Health and Welfare Association, the Council of Social Agencies, and the Medical Reference Library. In addition, there were operated here the dental, chest and psychiatric clinics.

Grace Hospital, New Haven, Conn.—This recent hospital report for 1927 illustrates certain features of good report making. The flyleaf pictures a child in a wheel chair with her nurse, both of whom appear cheerful. Beneath the photograph is a quotation from Phillips Brooks, "He who helps a

child helps humanity with an immediateness which is impossible at any other stage of human life." Well-selected photographs of the institution add interest and appeal. Headings are well placed in relation to subjects, paragraphs and position on the page. Statistical tables are informative and accompanied by descriptive text. The paper has a soft finish and is of good weight.

Winnipeg, Man.—The 1927 Health Department report of 162 pages is one of the best of the year. Following a table of contents, and the organization plan of the department, are pages devoted to the most important statistics, a financial statement, and the health officer's brief review of outstanding features of the year. The remainder of the report is devoted to bureau activities and results.

This city of 198,932 population records a general death rate of 8.29, a birth rate of 22.4, a tuberculosis death rate of 37.2, and an infant mortality rate of 61.17—all lower rates than previously reported for Winnipeg.

There were 48 cases of mild smallpox, with no deaths from this cause. Every case of chicken pox is checked and the diagnosis cleared in order that the possibility of smallpox being unrecognized may be eliminated. The diphtheria situation is analyzed in an interesting manner according to fatality rates in different wards of the city.

The outstanding feature of the diphtheria situation and the reason for the higher rate was a manifestation of increased virulence as compared with past years. A group of cases appeared in the central part of the city in which the infection was probably due to association of the diphtheria organism and the streptococcus. These cases were characterized by the presence of haemorrhagic sloughing membranes, high temperature, great prostration and rapidly fatal termination. In the early stages of these, the diphtheria organism was often not recoverable from throat cultures; later it appeared. Persons who were exposed to these cases developed the same type of disease as the patients. In one instance three people died in one household.

Toxoid administration in the public

and parochial schools and at the Bureau of Child Welfare was carried on throughout the year, as well as in various children's institutions, and there was no trouble from diphtheria in any of them.

The daily per capita consumption of milk and cream amounted to 1.06 pints, 58 per cent of the supply being pasteurized, 40 per cent raw tuberculin tested, and 2 per cent certified. No milk-borne outbreak of disease occurred. As a precautionary measure, all cases of sickness reported or suspected on dairies were investigated, and the majority of such cases were found to be of a non-communicable character.

Pittsburg County, Okla.—The 4th annual report for the year ending June 30, 1928, of the Coöperative Health Unit shows that this county of 52,000 population and area of 1,370 square miles was given 142 lectures on health education with an attendance of 4,600. Four thousand one hundred and fifty-three complete antityphoid administrations and 360 anti-smallpox vaccinations were made. Through one crippled children's clinic and school examinations, 17 major operations were found to be needed and were made under the crippled children's law of the state. The county had 1,078 births and 434 deaths during the year.

Scranton, Pa.—The 42d annual report for this city stresses the development of health education as a function of municipal health service. Eight lectures were given during the year on public health under the auspices of the department. On Child Health Day, 399 babies under 2 years of age were examined. Thirty-one hundred and forty leaflets on "Infant Care" were distributed during the year, as well as an approximate number of leaflets on communicable diseases. The city, with a population of 155,006, had a death rate of 10.7, a birth rate of 21.2 and an infant mortality rate of 13.7.

NEWS FROM THE FIELD

ITALY'S CHILDREN'S BUREAU

DURING 1927, the Children's Bureau of Italy, which administers the child welfare laws of that country, subsidized more than 1,100 child welfare institutions and agencies to the extent of 16,000,000 lire. Of these institutions nearly 700 were colonies at the seashore or in the mountains; these cared for more than 300,000 children.

An important innovation was the introduction of traveling centers for the instruction of mothers in child hygiene. Nine such centers, their staffs aggregating 55 persons, were established in 1927, which gave maternity care to more than 30,000 women.

During 1927 the bureau was instrumental in the enactment of regulations regarding measures dealing with wayward children, employment of women and children, admission of children to motion-picture performances and prohibition of the sale of tobacco and alcohol to young persons.

IMPROVEMENT IN ITALY'S MILK SUPPLY

A NUMBER of the more important cities of Italy, among them Rome, Naples, Milan, and Verona, have established "milk centers," where all milk intended for consumption is sent for sterilization.

Italy's first national conference on milk was held recently in Verona under Government auspices. It was brought out that while the annual consumption of milk per capita is 15 quarts in Italy, it is 90 quarts in England, 235 in Germany, and 265 in Sweden.

DR. LEWIS GRANTED LESLIE DANA MEDAL

THE Leslie Dana Medal was presented to Dr. Park Lewis, vice-president of the National Society for the Prevention of Blindness, on October 18, 1928, at St. Louis, Mo. The medal was presented "for the most outstanding

achievements in the prevention of blindness and the conservation of vision" in America.

This medal is given through the Missouri Association for the Blind, and it is one of the most highly prized marks of recognition in the public health field.

BLIND BABIES

THE State Legislature of New York has granted a budget sufficient to care for 35 blind babies and young children, in the institution maintained by the International Sunshine Society with headquarters at 96 Fifth Avenue, New York, N. Y.

OLEAN, N. Y., TYPHOID OUTBREAK

THE cause of the recent outbreak of typhoid fever in Olean, N. Y., has been traced to a break in the submerged pipe running from one of the South Olean wells to the pumping station, which allowed raw river water to be pumped into the main pipes, the amount of chlorine added being insufficient to protect against this pollution.

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS

A THREE-DAY series of conferences, November 26-28, inclusive, will be held under the auspices of the National Society for the Prevention of Blindness, in the Russell Sage Foundation Building, New York, N. Y. Industrial physicians, ophthalmologists, public health nurses, sight-saving class supervisors and others will participate in the conferences which will be held in connection with the 14th annual meeting of the society.

NEW COURSES AT COLUMBIA UNIVERSITY

THE Department of Health Education at Teachers College, Columbia University, announces two new courses of unusual interest. In the winter ses-

sion, there will be given a course in Methods of Teaching Lip Reading to Deafened Children, in coöperation with the New York League for the Hard of Hearing.

In the spring session, there will be a course on Methods of Teaching in Sight Conservation Classes. This will be given in coöperation with the National Health Council, and the National Society for the Prevention of Blindness. A sight conservation class will be developed as a teaching laboratory for this course.

WORLD'S LARGEST SEWAGE TREATMENT PLANT OPENED

DURING the week of October 8, 1928, the world's largest sewage treatment plant was opened in Chicago, Ill. The North Side Plant, as it is called, covers 97 acres and was built to purify the sewage of an ultimate popu-

lation of 1,340,000. Eight suburbs as well as a large section of the city of Chicago are served.

This plant was built as part of a program to dispose of the city's wastes without injuring neighboring communities.

A NEW FORM OF QUARANTINE CARD

THE following quarantine card used by Dr. H. J. Shelley, health officer of Middletown, N. Y., combines a bit of public health education with its warning.

NOTICE!

There is a case of communicable disease on these premises.

If someone had been careful not to infect others, this case would not have occurred. If you are careful—and do not enter while this placard is posted—you will neither contract nor spread the infection. Your co-operation is earnestly requested by

H. J. Shelley, M.D.

PERSONALS

DR. OREN NEWTON, of Taft, Kern County, Calif., has been appointed Health Officer of that county, to succeed Dr. H. M. Hawkins.

DR. WILLIAM SIMPSON, Health Officer of Santa Clara County, Calif., died on September 23, 1928, in San Jose, Calif.

DR. WILLARD W. NYE, Hiawatha, Kan., has resigned as County Health Officer of Brown County.

CARR T. DOWEL, Ph.D., has assumed the duties of dean and director of the college of agriculture and experiment stations at Louisiana State University.

L. L. DICKERSON, Executive Assistant of the board on the library and adult education, American Library Association, Chicago, Ill., has accepted the librarianship of the Indianapolis Public Library, and will assume his new duties some time after October 1.

EDITH GATES is the new head of the health education work of the National Board, Y. W. C. A. Miss Gates has recently been director of health and physical education in Y. W. C. A. centers in eight European countries.

GEORGE A. COOPER of the Monongahela West Penn Public Service Company, Fairmont, W. Va., has been appointed as an Assistant Chief Business Specialist in the Division of Simplified Practice of the Bureau of Standards, U. S. Department of Commerce.

DR. RUSSELL B. HOWARD has taken up the duties of full-time Health Officer of Bulitt County, Ky., with headquarters at Shepherdsville.

DR. EDWIN W. BATHURST has been appointed Health Officer of Edna, Calif.

DR. JAMES E. RUSH has resigned his position as head of the department and professor of hygiene and public

health at the University of Kentucky, Lexington, Ky.

DR. OSCAR M. CRAVEN has resigned as Health Officer of Springfield, O.

DR. ELLIS F. SWARTHOUT has been appointed city physician of Kenosha, Wis., to succeed Dr. O. W. McClusky, who resigned.

EDITH HODGSON, R.N., Santa Fe, N. M., has been appointed Chief of the Divisions of Child Hygiene and Public Health Nursing, to take the place of Dorothy Anderson, R.N.

DR. P. M. STEED has been appointed Health Officer of Luna County, N. M., to fill the place of Dr. J. G. Moir, who resigned recently.

EDNA C. SCHIERENBERG, R.N., has taken the position of Public Health Nurse of Dona Ana County, N. M.

DR. OLIVER L. AUSTIN of Tuckahoe, N. Y., has returned to Eastchester, N. Y., to resume his duties as Health Officer there. Dr. Austin was on an exploration trip to Labrador.

COLONEL ALBERT PFEIFFER, director of the N. Y. State division of Social Hygiene, has been assigned by the War Department to the 362d Medical Regiment as the commanding officer.

DR. EDWIN F. HOYT, Health Officer of Clinton, N. Y., died on October 4. Dr. Hoyt was 83 years old.

MARY A. BROWNELL, formerly assistant to the director of the National Organization for Public Health Nursing, has resigned to become associate director of Judson Health Center, New York, N. Y.

ELIZABETH C. BURGESS of New York, N. Y., has been elected president of the National League of Nursing Education.

CONFERENCES

November 7-10, Texas Association of Sanitarians, San Antonio, Tex.

November 8, Minnesota Public Health Association, Minneapolis, Minn.

November 8, National Committee for Mental Hygiene, New York, N. Y.

November 11-13, Kentucky Conference of Social Work, Lexington, Ky.

November 13-15, New York State Conference on Social Work, Rochester, N. Y.

November 23, New York State Association of Public Health Laboratories, Albany, N. Y.

November 26-28, National Society for the Prevention of Blindness, New York, N. Y.

November 26-28, West Virginia Public Health Council, Morgantown, W. Va.

December 13-15, American Vocational Association, Philadelphia, Pa.

December 26-29, American Association for Labor Legislation, Chicago, Ill.

December 27-29, Society of American Bacteriologists, Richmond, Va.

December 27-January 2, American Association for the Advancement of Science, New York, N. Y.

December 28, International Congress of Tropical Medicine and Hygiene, Cairo, Egypt.

December 29, American Student Health Association, New Orleans, La.

The Hooper Foundation for Medical Research at the University of California is anxious to obtain recently isolated cultures of *B. proteus*, especially those from foods or those involved in outbreaks of food poisoning.—Address J. C. Geiger, Associate Professor of Epidemiology, University of California, San Francisco, Calif.

Selling Health—a Vital Duty*

HERMAN N. BUNDESEN, M. D., Sc. D., FELLOW A. P. H. A.

Health Editor, Chicago Daily News, Chicago, Ill.

IF there is one word more than any other being broadcast in these times, it is the word "Health." More and more the American people are being awakened to a profound realization of the importance that attaches to that word. And not much longer will it be said with truth that greater attention is given to the care of a hog than to that of a human being.

The last decade has witnessed many important advances in America's public health. Each year sees the status of the last eclipsed. But much remains to be done. The thoughts which dominate me are concerned with the important rôle that still remains to those who can and should "sell" health.

Perhaps it may seem to be needless repetition to talk about health publicity. Certainly what I can contribute on this subject is not new, and it may be especially boring to those who are experts on publicity. However, because health publicity has been much discussed, I fear the opinion may be growing that it is a branch of public health science that has matured, and whose functions are established. Unfortunately this young branch of our profession is still in its infancy and its opportunities are still mainly in its future.

Reiteration may dull the glamour of its romance, and may make a bromidic bore of a great tale. We must recognize that years and decades of persistent hammering away at the individual's indifference is necessary, and only by this means will we rouse him to the lessons that should come to him from health propaganda.

How many of you, proponents of health, whose business it is to further the health of the people, sell this commodity called "Health"? Every big business that has something to sell, spends vast sums of

* Presidential Address, delivered before the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 15, 1928.

capital to train and send out live, alert and efficient salesmen. No other business in the world is bigger than that of keeping people well. Why then shall we lack enthusiastic, efficient health salesmen?

If it still needs to be done, we can manufacture two axioms: "Health is a saleable commodity"; and "There is a good market for it all of the time with all of the people." These things are true if health departments and great bodies like the American Public Health Association have the desire and will to create the market and exploit it. You remember that one of the common phrases of the recent war was "carry on." It is up to us who are in the front ranks of health promotion to create the market and then to "carry on" in the cause of this good work.

Mere laws to enforce health do not create health. A desire for good health must first be aroused, stimulated by knowledge of its value and means of attainment. Then the health salesman must come in. Time was when people used to "enjoy" poor health, but that day is going by.

Every health worker should be a health salesman, and to be a good salesman he must know his wares thoroughly. He must have absolute confidence in his line, for to make others believe, he himself must first have the convincing enthusiasm of a great belief.

The health officer who is in the business of selling health must also have sound health himself and must surround himself with evidence of it. If he has small children who are constantly ailing, he cannot argue convincingly for an infant welfare clinic unless he utilizes such or a similar facility himself. If he has a set of neglected teeth, he cannot well convince the community of his belief in the efficacy of a dental clinic.

If the health officer's house or office is insanitary or unscreened, if he and his family sleep with the windows closed, if his personal habits are not the habits of good health, he belies his teachings; gives a bad example; and sets up a most powerful argument against the very things which he is trying to sell. He must not be a health prostitute. Remember that health is more easily caught than taught.

The health officer who urges eating a proper diet, and then does not live by his teachings, cannot expect the community to follow his advice. He must carry his faith into daily personal practice. Who does not know how difficult it is to induce people to use an article unless he himself uses it?

Disease and sickness must be exposed to the cleansing light of universal knowledge. They are largely maintained because of the public's ignorance of what health is and how to keep it.

The efficient health salesman must come in, even more than he has attempted in the past. He must talk health and talk real facts, not surmises. He must be scientific, specific, optimistic; and he must use every available means to reach his audience.

Publicity is the best medium to accomplish these ends. Publicity we have employed, but insufficiently and often by methods that call for radical change.

The first quality of health news must be its accuracy. I preach the lesson that experience has taught me. No publicity should ever be released by the health official unless it has been edited and has met the approval of the technical expert. The context must be right before it is worthy of release.

The value of good health news, published in the right way, is still too often neglected by health authorities. Such news must be the kind that sells health to the community. If it is prepared for reading, it should be prepared in readable print, well spaced, properly headed and paragraphed, thoroughly illustrated, and well printed. Similarly, other forms of publicity should be adequately prepared. An optimistic viewpoint and a cheerful attitude should always be maintained. The sentences should be short and the words simple, so that they may be understood by all who read, including the young and the foreign born.

Simplicity appeals. Need I remind you of the great words that have lived? The whole lesson of prayer was taught by Jesus in a petition of sixty words. The Lord's Prayer is probably more generally known than any other verse. How simple its diction and rhetoric! Were it as complicated as our national anthem not one in a thousand could repeat it. The most wonderful poem in the Bible, the Twenty-third Psalm, consists of 118 simple words. Consider its brevity, its simplicity and its clarity. It is universally known, and probably holds more truth and religion than any other composition of similar length. The world has been slow to learn many of the lessons in the life of Jesus. One of them which is often given little attention, but which is of great importance to preacher, lawyer, orator, hygienist and to a man making a presidential address, is the blessed virtue of being brief.

The greatest speech of all time was given by Lincoln at Gettysburg. Why is it so great? Primarily because of its simplicity and its brevity. Let simple language carry your message to the people.

Few of us can write as the Prophets wrote; and none of us can repeat the feat of Lincoln. *But we can follow*, for the guides they left us are plain and permanent.

Other means we may use; but above all, the press, the greatest molders of public opinion today, the movies, and the radio, must be our media through which we shall build the Empire of Health. Inoculate these media with the seeds of health facts and they will infect the people with messages both gripping and convincing. Health will be even more contagious than sickness is now.

In a hundred years in our country the death rate has been cut in two. The credit for that, in my opinion, is in great part due to public health activities and publicity.

The same means by which such countless lives were saved are in your hands today, but they have not been used to their full possibilities. We must strive ever more vigorously in tuberculosis and cancer control. But if we just apply the methods that are now generally known to be life saving and health producing, as many lives can be saved in the next two decades as were saved in the past century.

I say to you, and it is my conviction, that one of every three deaths among American citizens could be prevented if the utmost in intelligent health education were attained.

The figure is astounding. Think of saving 500,000 lives a year in this great nation of ours! You men who sit at health administration desks and scan the death certificates—you know how many of them carry the tragic story of a life lost that should have been saved.

Hence I say that our aim shall be to sell health. The Lord promised to man, in the Old Testament: "And his days shall be an hundred and twenty years." We should strive to give him his biblical quota, and let him have a century of life, at least. And while we add years to his life, let us be sure to add life to his years, and make them hale and vigorous.

Moreover, we should add lives to the nation by saving babies, preventing epidemics, by carrying our knowledge of health giving and life saving measures to the humblest citizen of the lowliest hamlet in the land.

My plea is that you live health, talk health, sell health and think health. Sell it alike to young and old. Sell it by example and precept; by good health news published in the right way; through the press; by the motion picture, the radio, slogan and poster, or in any other way you will. But *sell* it. Science may outstrip public knowledge, but hygiene must remain to serve the people.

Practical Points about Active Immunization against Diphtheria and Scarlet Fever*

WILLIAM H. PARK, M. D., FELLOW A. P. H. A.

and

MAY C. SCHRODER, M. D.

*Director and Assistant Director, Bureau of Laboratories, Department of Health,
New York, N. Y.*

PROBABLY the most important point at present under discussion in the immunization of children against diphtheria is the preparation to be used. There are four preparations now available: toxin, nearly neutralized with a trace of antitoxin produced in horses; toxin nearly neutralized with antitoxin produced in goats; and toxin modified by exposure to moderate warmth and a small amount of formalin, so that it becomes practically free from toxic action. This is called anatoxin or toxoid; and finally toxin modified by the action of formalin to a lesser extent so that it is chiefly toxic. This is also called toxoid but not anatoxin.

In the United States and Germany, toxin-antitoxin is chiefly used, in France, anatoxin, and in England and Canada the slightly toxic or non-toxic toxoid. The choice of the different peoples is largely accidental and to some degree influenced by patriotic reasons rather than by the especial value of the product.

Ramon recently has contrasted the virtues of anatoxin with the drawbacks of toxin-antitoxin.¹ The recognized importance of Ramon's opinion because of his having developed anatoxin causes us to consider his objections in detail.

His first objection is that toxin-antitoxin is very difficult to make and that because of this difficulty serious accidents have occurred and probably will occur in the future from its use. Having produced both preparations, we are certain that both are made without difficulty by experienced workers.

As to accidents, there have been three major ones and one minor. The first major accident was at Dallas some years ago, where through

* Read before the Health Officers Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

a mistake a preparation was sent which contained a large amount of free toxin and a number of deaths occurred. The next was in Vienna, where due to carelessness vials of dilute toxin were sent out which were of similar appearance to those holding toxin-antitoxin. Some of these were used in place of toxin-antitoxin with serious results.

The third accident was in Australia where toxin-antitoxin was sent out without any antiseptic. This was contained in rather large bottles from which the product was taken from time to time for the injections. The third drawing from the contents of one bottle taken some days after the first caused a number of deaths. The examination showed that the fluid was badly contaminated by virulent staphylococci. The first two drawings from this bottle had produced no injury, so that it must have become contaminated during the second drawing. These accidents were all due to carelessness and certainly had nothing to do with the nature of the preparation.

The minor accident happened in Boston several years ago when the surprising fact was discovered that freezing of the old preparation temporarily separated from its combination in the toxin-antitoxin enough toxin to cause on its injection serious but not fatal reactions. This separation does not take place with the present universally used 1/10 L + mixture. This objection of Ramon, that the nature of the preparation of toxin-antitoxin leads to accidents, is certainly not founded on fact. We have never had any accidents in New York City from its use in hundreds of thousands of children. Ramon's second objection is that toxin-antitoxin is slow in producing immunity. In our experience, which is quite large, there is no appreciable difference between the two preparations. Different preparations vary in their immunizing potency and, of course, if a good one of anatoxin is contrasted with a poor one of toxin-antitoxin there will be a difference.

Ramon's third objection has more validity and has been voiced by many. It is that the minute amount of horse globulin added to the toxin sensitizes those receiving it to later injections of horse antitoxin or other antibodies, such as are used in tetanus, scarlet fever, meningitis and diphtheria. He fails to realize that the objection if well founded can be easily obviated by substituting goat or sheep produced diphtheria antitoxin for that produced in the horse. This is already being done extensively and on an increasing scale. The goat and the sheep are sufficiently widely separated in species from the horse, so that at least in the amount used their serum does not sensitize persons to later injections of horse serum. Should this change be made? There is no doubt that the percentage of minor skin reactions following intracutaneous tests increases for a time in those who have had injections

of horse antitoxin-toxin, but in several instances where we have had the opportunity of comparing the reaction in large groups of children, there has been no appreciable difference between the reactions in those who had and those who had not had toxin-antitoxin previously. There is also no doubt that reactions due to serum have been improperly laid to sensitization by previous injections of toxin-antitoxin.

Certainly no serologist would agree that such an example as that recently recorded in the *Journal of the American Medical Association* was due to sensitization by toxin-antitoxin. A nurse one year after having been immunized with toxin-antitoxin developed sinus trouble with a possibility of a complicating diphtheria. Ten thousand units of diphtheria antitoxin were given. Four days later she developed a moderate case of serum sickness. Ten days after having received the dose of antitoxic serum she was given another dose of 20,000 units; she immediately developed an alarming attack of serum sickness. There was marked swelling in the tissue of the thigh where the serum was given. This finally progressed to such an extent that local gangrene developed. The sensitization here was certainly due to the injection of the serum given ten days earlier and not to the toxin-antitoxin of the previous year, for otherwise the severe reaction would have developed with the first dose of serum.

While it is true that we are more accustomed to using horse antitoxin to add to our toxin and that we do not ourselves fear sensitization, yet because many physicians fear the minute amount of horse serum, we think we should within a reasonable time substitute goat antitoxin for the horse antitoxin. Both preparations give equally good results. It is the antitoxin and not the animal which produces it which is of importance.

The problem remains as to whether goat or sheep toxin-antitoxin or anatoxin is the better immunizing agent. We have found each preparation when properly selected to be equally good. An injection of toxin-antitoxin gives somewhat less reaction in the children of school age, and the toxoid or anatoxin in infants and the younger preschool children. Fortunately, therefore, each health officer can choose the preparation he prefers, and if it has been properly tested for potency in the laboratory, he can count on good results.

The next subject we choose as appropriate to take up is a modification of the Schick test. The extra labor involved in the Schick test has caused its pretty general disuse in the campaign for the active immunization of preschool children, and in country districts in the school children also. Five years ago we tested the possibility of using the first dose of toxin-antitoxin as a test for immunity as well as an

immunizing agent. We found that the properly standardized preparation of which the injection of 1 c.c. would usually cause the death of a 250 gm. guinea pig, would serve the double purpose. It should be given strictly subcutaneously and as superficially as possible. We found the anterior part of the arm just above the elbow the best place for the injection. Anatoxin cannot be used for this purpose, as the reaction due to its injection is produced by other proteins and not by diphtheria toxin. In young children the toxin-antitoxin reaction parallels the Schick reaction. In older children there is a 10 to 20 per cent increase of positive reactions. Some of these are persistent pseudo reactions. The error if present is on the right side. The reading of the reaction should be delayed until the 6th or 7th day to allow the pseudo reactions to largely disappear. Inspected on the 6th or 7th day, the children showing a reaction are given a second dose, while those showing no reaction are allowed to go without further treatment. A week or 10 days later, the third injection is given. In those using this method for the first time, it is well to control the test in some of the children by an additional Schick test. We have found this method a very useful one where the Schick test is not to be done. It is in use in the public schools and in the baby health stations in New York City. This test should not be substituted for the Schick test in a retest.

The Retest—As three injections of even the best preparations of toxin-antitoxin or of anatoxin or toxoid do not give over 90 per cent immunity on the average, a retest should always be suggested. If the offer is not accepted, the health officer has at least done his part. Without this test, no parent is certain that the child is immune. The retest should not be done earlier than the end of 3 months, as some children are slow in developing immunity. With a retest a control test is always advisable.

Should those who have once been successfully immunized be re-injected in later years? Our experience has taught us that there is a slight tendency for a small percentage of cases to gradually revert to their former positive condition. It is very hard in cities to follow the children. They leave their institutions or move to new homes and addresses are lost. We have been able, however, to follow a few children and a much larger number of adults. The following summaries give the results of retests made 8 years after the original injections.

THE PERSISTENCE OF A NEGATIVE SCHICK TEST IN CHILDREN WHO
WERE IMMUNE THROUGH NATURAL CAUSES OR WHO WERE
IMMUNIZED BY TOXIN-ANTITOXIN

Eighteen infants and young children who gave a negative Schick test in 1919 when retested in 1926 were all negative.

Twenty-five infants and young children who were positive in 1919 and received 2 injections of toxin-antitoxin when retested in 1926 gave negative reactions in 23, a positive reaction in 1 and a doubtful reaction in 1. This was probably a pseudo reaction.

Either 92 or 96 per cent retained their immunity.

THE PERSISTENCE OF A NEGATIVE SCHICK TEST IN ADULTS WHO WERE IMMUNE THROUGH NATURAL CAUSES

Twelve hundred and ninety-five adults tested in 1920 gave 1,115 negative reactors with no pseudo reaction and 180 negative pseudo reactors.

At the retest in 1928 the 1,115 which had given no reaction gave the following results: 990 were absolutely negative, an additional 144 were negative but gave a protein or pseudo reaction.

Forty-nine gave a positive reaction without a pseudo reaction and 32 gave with a positive reaction also a pseudo reaction.

The results indicated that 93.4 per cent retained their naturally acquired immunity for 8 years.

The 180 which were considered to have given a negative pseudo reaction showed the following results at the retest in 1928.

Fifty-eight gave negative reactions; 91 gave pseudo reactions; 7 gave positive reactions; 24 gave combined reactions; and 83 per cent remained immune.

THE PERSISTENCE IN ADULTS OF ACQUIRED ACTIVE IMMUNITY AS SHOWN BY A RETEST 8 YEARS LATER

One hundred and seventy-eight adults originally giving a positive Schick test became negative in 1920 after 1 or 2 series of 2 injections of toxin-antitoxin.

Retested in 1928 the following results were obtained:

	Per cent
81 were negative without pseudo reactions	45.5
30 were negative with slight pseudo reactions	16.8
34 were probably negative with marked pseudo reactions	19.0
33 were positive with or without lesser pseudo reactions	18.5
	62.3
	81.3

We find therefore that 62 per cent retained their immunity and that an additional 19 per cent probably did. It is fair to consider that at least 75 per cent of those actively immunized retained and 25 per cent lost their immunity obtained through the stimulus of toxin-antitoxin. There is a possibility that this immunity may have been reinforced in some way by their having become carriers of diphtheria bacilli at some time during the 8 years.

The results of these tests suggest that the lapses are not great enough to make it necessary to reinject or retest as a public health measure. Children seem to hold their immunity somewhat better than adults, possibly because non-immune adults have shown a resistance to the natural causes which produce immunization. We must remember that in time of exposure we are never certain that a person's immunity has persisted.

Is a negative Schick test a guarantee of immunity? We have not space to consider this fully. If there is sufficient antitoxin in the skin

of a child to neutralize an intracutaneous injection of one-fiftieth of a minimum fatal dose of toxin for a guinea pig, we do not believe that a child can develop diphtheria. Nevertheless, we should always advise that antitoxin should be given in any child really suspected of having diphtheria. Why? The technic of the injection of the diluted toxin may be incorrect in a given case such as the needle going a little too deep or the full amount of fluid not being delivered or the toxin may have lessened in potency because of aging or because of being preserved in improper glass. We must not think, on the other hand, that because a case has a positive culture the case is necessarily one of diphtheria. A case of tonsillitis due to other germs can perfectly well be a carrier of either virulent or non-virulent diphtheria-like bacilli.

ACTIVE IMMUNIZATION AGAINST SCARLET FEVER

It is doubtful whether we have made striking progress since Gabrischewsky in 1907 proposed the use of a vaccine made of the culture fluid and streptococci. Since his first dose of 0.5 c.c. of vaccine produced a rash like that of scarlet fever in 13 per cent of the children, it probably contained between 2,500 and 5,000 Dick skin test doses. As the second dose was double the quantity of the first, and the third was double the quantity of the second, he probably gave in the three injections about 25,000 skin test doses. Gabrischewsky died shortly after he published his results; but his work has been carried on by others. They report that the vaccinated children in the villages of Russia where scarlet fever is abundant rarely develop scarlet fever, while the unvaccinated frequently develop it.

The brilliant discovery of the Dicks that the filtrate of the culture could be used when given in proper dilution as a test for immunity in the same way as the Schick test for diphtheria, enabled us to decide on those who needed immunity; gave us a method of determining the duration of immunity; and allowed us also to estimate the amount of toxin given in the immunizing injection. It was found that moderate amounts given in three to five doses at intervals of 1 week or more produce immunity in a short time in the vast majority of children.

EARLY IMMUNIZATIONS IN NEW YORK CITY

Our earliest attempts to immunize children were made with comparatively small amounts of toxin. At first we gave only 1,500 skin test doses divided into three injections. We found fairly good results so far as immunization was concerned, but it did not hold. We then increased the amount to 4,000 and then to 12,000. We got very good results with 12,000 skin test doses divided into five injections. These were: 700, 1,200, 2,100, 3,000 and 4,000 skin test doses. At the end

TABLE I

RESULTS OF INJECTING 200, 400 AND 800 SKIN TEST DOSES AS SHOWN BY RETEST 5 AND 13 MONTHS AFTERWARDS AT ST. DOMINICKS

Original Retest at 5 months %	13 months %
One hundred + + = 0	+ + = 20 very susceptible
positive cases + = 8 = 9.8	+ = 9 susceptible
of St. Dominicks ± = 27 = 33.3	± = 14 doubtful
Test by — = 46 = 56.8	— = 57 immune
Dr. Schroder	—
Total 81	Total 100

of 4 weeks, 91 per cent of the children gave negative Dick tests and 7 per cent gave doubtful tests, leaving only 2 per cent definitely positive. Even with these larger doses we found immunity did not last beyond 6 months in many of the more positive children. We then still further increased the amounts with the hope that the duration of immunity might be greatly increased. The doses we are now using are 1,000, 5,000, 10,000, 15,000 and 15,000 to 30,000 skin test doses. The injections are given at weekly intervals or at slightly longer intervals.

The following three tables give an idea of the changes which have taken place in dosage during the past few years. Similar changes have taken place in the practice of others. Thus in the *Journal of the A. M. A.*, May 16, 1925, the Dicks give a table showing the increased amount of immunizing power of different doses. Thus when 1,000 to 2,000 skin test doses are given they find 14 per cent of the children become completely immunized; when 5,000 to 6,000, 66 per cent, and when from 10,000 to 12,500, 91.8 per cent.

Before the publication of this table we obtained some interesting results on retests which are seen in Table I. Although from 1,000 skin test doses divided in 3 injections, we found on retesting at the end

TABLE II

RESULTS OF FIVE IMMUNIZING INJECTIONS AT THE END OF 3½ MONTHS APPROXIMATELY 500, 1,000, 2,000, 3,000 AND 4,000 SKIN TEST DOSES

	After 3½ Months
32 + + or + + 1	1 = + 81% immune
Strongly positive cases	5 = ± = 17% probably immune
	23 = — = 2% probably susceptible
	*3 = ± negative pseudo
37 + or + 1	34 = —
Moderate reactors	*1 = + negative pseudo 100% immune
	*2 = ± negative pseudo
69 + to + + 1	1 = + 91% immune
All positive reactors	5 = ± 7% probably immune
	57 = — 1% probably susceptible
	1 = + negative pseudo
	5 = ± negative pseudo

* 1 + and *5 ± are considered negative pseudo reactions because of an equal reaction in the control neutralized by convalescent serum.

of 5 months no strongly positive reactors remaining, and but 10 per cent of moderately reacting. At 13 months, however, we found 20 per cent again giving strong positive reactions. The Dicks and others had the same experience and so the doses and the number of injections have been mounting until they are giving 5 doses containing altogether over 100,000 skin test doses. These large doses are given wholly with the hope of producing a more lasting immunity in the strongly reacting children. They give to about 98 per cent of positive children a negative Dick reaction. Table II shows that with 10,000 skin test doses very good results for the immediate season were obtained by us. Table III gives the results in our children following larger doses. In the course of another two or three years we will definitely know whether in order to obtain prolonged immunity we should give 100,000 or more test doses.

TABLE III

RESULTS AT DIFFERENT INTERVALS AFTER GIVING LARGER DOSES OF SCARLET FEVER TOXIN
DIVIDED INTO 5 DOSES

No. Children Giving Positive Reactions	Time Since Immunization of Retest	Amount Toxin	Per Cent Immune
40*	6 months	31,000	71
69	8½ months	46,000	84
56	11 months	31,000	68
11	14 months	31,000	82
19	15 months	26,000	80
16*	2 years	31,000	37.5

* The number watched for two years is too small to be considered as determining the average duration of immunity.

The persistence of immunity in those who have become naturally immune is encouraging. Thus we found:

RETESTS ON CHILDREN ORIGINALLY NEGATIVE

Of 140 negative children 27, or 19 per cent, were moderately positive 13 months later. Those cases which show pseudo reactions equal to the toxin reaction are called negative-pseudo although they may be combined.

In the general local treatment of the children receiving the immunizing injections, we have found it useful to give them a laxative on the day of the injection and to apply wet dressings, usually using boric acid solution, to any children who show an inflammatory reaction in their arms. With these doses we have not had any general rashes develop but the first and second doses sometimes cause a local inflammatory reaction and sometimes vomiting and a rise of temperature.

The Russians still continue to give with the toxin the dead streptococci as first suggested by Gabrischewsky. Whether this method has any appreciable advantage over the pure toxin is doubtful. The aim is to develop antibacterial as well as antitoxic immunity. Some of the American biological plants also distribute such a vaccine. The Larsen preparation of toxoid has been employed by many. We have

found that four or five doses are required to obtain nearly 100 per cent of immune children. It does not seem to us to have any advantage over the toxin.

THE CONTROL TO THE DICK TEST

In making careful tests for immunity to diphtheria, we give alongside of the Schick test a control test of heated toxin. The toxin itself is slow in developing a reaction and this does not reach its height until the 4th day, while the protein substances left in the heated toxin produce in sensitized persons a quick reaction which is generally of short duration, although in a few cases it may persist for several weeks. With the Dick test the toxin acts like the pseudo reaction in the Schick test as well as that from the control heated toxin in the Dick test—that is, the Dick test and the control test give identical reactions which show their greatest extent at the end of 24 hours. It is therefore impossible to be sure when the control test is similar to the Dick test whether it is a pseudo reaction indicating immunity or a combined reaction indicating susceptibility. In children who have received no vaccination, there are few pseudo reactions, but in those who have received the large injections of vaccine now in vogue, we get a good many pseudo reactions. An added difficulty is that even boiling for 3 hours does not destroy all the toxin. This is determined by the fact that the apparent pseudo reaction in some children is prevented by mixing the boiled toxin with scarlet fever convalescent serum. There is a considerable difference in the amount of pseudo reactions developed by the injection of different preparations.

THE RELIABILITY OF THE DICK TEST

The Dick test in our opinion is almost, but not quite, as reliable as the Schick test. The same care must be taken that the toxin is properly standardized and that it is placed in vials of proper glass. The toxin is more resistant than the diphtheria toxin and can be distributed already diluted. The difficulty with the Dick test is that, as the toxin can only be properly tested in the skin of human beings, it is not apt to be as thoroughly tested as the diphtheria toxin. Also because there are other streptococci which belong to different types which cause fever and scarlet rashes, these may infect those who give a negative Dick test. Such streptococci are, however, in a great minority. The Dick test as a retest is less reliable because of the occasional difficulty of separating the toxin reactions from the pseudo reactions. The occasional errors are however on the safe side.

How generally should scarlet fever vaccination be employed? This is a very debatable question. In the first place, scarlet fever at

the present time is a rather mild disease in most sections of the country. The deaths in New York City, for instance, are less than 1 in 100,000 persons. The cases, however, amount annually to 10,000 to 20,000. The five doses of the toxin are also a disadvantage. While immunization is rapid it is not always lasting with our present dosage in those who were strongly positive. We cannot yet expect to develop an immune population. In a personal communication the Dicks inform me that the injection of a total of 100,000 or more skin test doses divided in five injections produces an immunization in about 98 per cent which lasts for at least 2 years. At present therefore we only urge that it be given to all nurses who expect to be in contact with scarlet fever and to all children in institutions. We advise that it be used in schools and families where exposure to scarlet fever is imminent because of outbreaks in the neighborhood. When a case of scarlet fever breaks out in a family or institution, we prefer to do a Dick test on the inmates and to begin active immunization of those who have been exposed or who may be exposed rather than to give scarlet fever antitoxin. The scarlet fever antitoxin only gives an immunity lasting from 10 days to 2 weeks, and at present is more apt to produce serum sickness when injected into human beings than does diphtheria antitoxin.

Industrial Fatigue*

EUGENE LYMAN FISK, M. D., FELLOW A. P. H. A.

Medical Director, Life Extension Institute, New York, N. Y.

THE conventional attitude toward industrial fatigue carries with it the implication, however latent, that work is a health liability and that fatigue is a functional disease superinduced by work, and that, therefore, any move toward a shortened workday or work week is in the direction of greater freedom, health, and happiness. My concept of fatigue carries the implication that work, within reasonable bounds, is one of the greatest stabilizers of health that we have; that fatigue, which is not superinduced by a condition of physical impairment and deficiency, is a part of the normal rhythm of life and a condition to be welcomed as one necessary in maintaining the balance of mental and physical health.

It seems first necessary to arrive at as clear an idea as possible of what is meant by industrial fatigue. As shown by a study of the *Bibliography on Industrial Fatigue and Allied Subjects*,¹ fatigue researches heretofore have been directed almost wholly to the supposed effects of industrial work upon the muscular or nervous state of the individual, and practically the only attainable criterion has been that of the work curve.

There is a preponderance of opinion in favor of the thesis that industrial fatigue arises in the nervous system rather than in the muscular system. However that may be, it seems desirable that the study of physiological fatigue—the reaction of the worker to any form of work or environment—should be studied in groups reasonably normal as to their physical state as compared to groups showing some departure from the normal which might conceivably be either partly or chiefly responsible for either an unfavorable work curve or a conscious state of fatigue in the individual.

At the present time the trend of opinion seems to be against the view that there is any specific fatigue toxin affecting the muscles and it may well be that a variety of toxins derived from bacterial action rather than from muscular work affects both the nervous system and the muscular system.

* Report of the Committee for the Study of Industrial Fatigue, presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 16, 1928.

It is rather remarkable that in the 440 references given in the Bibliography¹ there are only 9 articles which deal specifically with the intrinsic factors contributing to fatigue—those present in the individual at the time of going to work as contrasted with environmental factors such as the nature and degree of work or working conditions—and there were 10 touching lightly upon these intrinsic factors. The balance are devoted wholly to the consideration of extrinsic or environmental factors as responsible for that impairment of working capacity which has been loosely termed "fatigue." Evidently here is a fertile field for research and for a readjustment of the attitude toward the whole subject of fatigue study.

So comparatively negligible a factor as the color of the walls in a work room has been given serious consideration, while the possible influence of such definite conditions as septic tonsils or defective vision as a factor in fatigue has been given little attention. If more than half of the people in such a room have faulty vision, uncorrected—as we find to be true in average groups—which is more important, to seek out this faulty vision and correct it or merely to mitigate the fatigue of these strained eyes by changing the color of the walls?

The ideal advanced by certain efficiency experts in finding the one best way of doing a piece of work in industry may have some merit. But the fundamental need is better expressed in the ideal of attaining the best physical and mental state in which to do this work.

The conventional view arises from the unfortunate fact that in industry it is too generally assumed that there are 2 classes of people, the sick and the well. That the majority of workers who do not report on the sick list are far below a condition of physical efficiency is a factor too generally ignored. It needs but little thought or examination of the subject to convince any reasonable man that there is a wide range of possible intrinsic factors affecting the work curve which have nothing at all to do with the hours of work, the kind of work, or the environment in which the work is carried on. It is indubitably true that a half-sick man will be benefited and his work curve improved by mitigating, through improvement of his environment, the demands made upon him. But the question may be sharply raised as to whether or not this is a method leading to a fundamental or maximal correction of those manifestations grouped under the term "industrial fatigue."

I am pleading for a balanced study of this whole fatigue question in which each line of research shall be properly weighted. The physiological studies must be continued. However, these studies seem less important than the larger objective of ascertaining the total

physical condition of any working force, and of estimating what sources of waste, inefficiency, and non-productivity there may be in actual physical disability, especially that not reflected in the absentee rate or sickness rate.

Attention is called to the great importance in industry of detecting what is termed "silent sickness," the chronic disease which actually contributes more heavily to the death rate than the acute types of disease reflected in the absentee rate in industry. We should ascertain the part played by these chronic maladies in lessening the efficiency of the industrial worker and shortening his work cycle.

In certain lines of industry true fatigue is a major problem; that is, assuming that all workers engaged in a particular industry were fully up to standard physically, there would be in that group a strain involving the nervous and muscular systems that would constitute a real problem and require adjustment of working conditions and working hours. In all plants it is a consistent and meritorious objective to adjust both working hours and methods on the best possible plane. What that plane is, however, is difficult to determine without specific studies.

It seems highly desirable to investigate the work reaction of representative groups of employes, ranging from those who upon careful examination appear to be in a state of comparative freedom from physical defects or mental or nervous insufficiency to those who are really seriously impaired. The entire range of these possible conditions will be found in any fair sized group of working people who have *not* reported on the sick list and are supposed to be just ordinary healthy workers.

One of the most striking instances of an intrinsic factor affecting the work curve was revealed in the studies made by the U. S. Public Health Service² in the investigation of acid sodium phosphate in delaying the onset of fatigue. Emden³ reported a favorable effect of this substance in delaying the onset of fatigue among soldiers during the late war, and it was assumed that it constituted a chemical antidote to fatigue poisons or supplied some chemical lack in the working muscle.

The result of these experiments indicated that acid sodium phosphate did not appear to increase muscular efficiency but that it induced a feeling of well-being especially among those who were somewhat below par when the experiment started. This, in the judgment of the investigators, was at least partly related to the correction of intestinal stasis. There was noted a distinct improvement in the bowel function among those using the phosphate.

The significant fact bearing on the thesis of this paper is that 80 per cent of the people in the group investigated suffered from a physical disability that was manifestly reflected in lowered physical efficiency.

The difficulty of determining a base-line from which to judge fatigue and other complicating factors rendered difficult any positive conclusions with regard to the effect of the phosphate on the work curve of the group under consideration, although Emden's conclusions from his own experiments were quite positive as to the beneficial effect on endurance and production.

The question raised by this investigation as to the possible effect of bowel sluggishness in inducing fatigue is worthy of more comprehensive study. Yet constipation is only one among manifold possible intrinsic factors influencing the efficiency and productivity of the employe.

The opinion that merely lightening labor is applying the best remedy to fatigue conditions contains a fundamental fallacy in so far as it relates to correcting that unfavorable deviation in the work curve that is so generally regarded as reflecting industrial fatigue. The proposal is frequently made that we adjust the job to the man. But for a really fundamental solution of the problem, the best approach would be to adjust the man to the job; that is, to study his condition and so far improve it that his working limitations would be expanded, rather than to compromise with his working limitations and let him settle down into a sub-standard job.

It is impossible to consider this question of fatigue without being at once led into the question of the longevity of the worker, his physical efficiency at the various decades of life, and therefore of the final problem of why the worker in industry is assumed to be more or less a liability at middle life and later. There is a certain naivete in so carelessly discussing all of these fatigue states as a reflection of work itself and then accepting the dictum that the worker suddenly, without previous ill health, becomes say at age 50 (on the average) a liability in the plant.

Secretary of Labor Davis has bitterly deplored this traditional attitude toward the man of 50 and speaks of the time when at that age it was customary to give a man a gold-headed cane and gracefully bow him out of the plant. Of course a broader view is taken of this question now and in many plants there is a real effort made to adjust every kind of work to the older workers who have been highly trained and who have served their employers faithfully. This is a very wise policy as far as it goes, but a very unwise policy if it stops there.

Through a right approach the need for adjustment of working conditions to the elderly man will be lessened, or rather the age at which such adjustment is considered important will be pushed forward and the liability point fixed nearer 60 than 50.

These views are advanced in the hope that in all research centers in industrial hygiene where industrial fatigue is given considerable thought, there may be a readjustment of the mental attitude toward this problem and an approach from a wholly different angle than has heretofore been customary in fatigue studies or in efforts toward the mitigation of fatigue.

No one can question the scientific wisdom or the practical sociological value of adjusting working conditions on such a plane that the worker shall have sufficient time for a broader life and for true self-expression. But no real progress is made in that direction by falsely presenting the effect of working conditions on the human organism. Error and misunderstanding on this question will be avoided if the effects of work and environment are measured upon workers graded according to their physical equipment. Then there will be presented a true picture of the man at work.

German Work for Psychopathic Children

SPECIAL provision for the welfare of psychopathic children is made by the municipal children's bureau in every large city in Germany, in accordance with the federal child welfare law of 1922, which constituted this work as a function of these bureaus. The work in each city is in charge of a psychiatrist, who is aided by trained visitors, and it is done in close coöperation with public schools, juvenile courts, and other agencies interested in child welfare. In some cities emphasis is laid on change of environment for these children, and they are placed in special institutions. In certain cities special day schools, including kindergartens, are provided for them. In other cities, psychopathic children attend the regular day schools and go periodically to a consultation center, which sends workers to visit these children at their homes. Annual reports from all the municipal children's bureaus stress the importance of psychiatric work as a branch of general child welfare work.—*Ztschr. f. Kinderforsch.*, Berlin, Aug. 25, 1928, p. 522.

The Use of Ultra-Violet Light Transmitting Windows*

WALTER H. EDDY, PH. D.

*Laboratory of Physiological Chemistry, Teachers College, Columbia University,
New York, N. Y.*

A NEW industry and a new line of selling talk have sprung into being within the past few years. To one informed as to scientific progress in irradiation as a means of controlling lime utilization in the body and of preventing rickets, the promotion of this particular industry is highly important and desirable. The selling talks of salesmen endeavoring to convince prospective customers demand critical evaluation and constructive suggestion to eliminate claims made without basis in fact.

The industry to which I refer is that concerned in producing window material which, correcting a defect of ordinary window glass, will transmit in addition to the illuminating rays those shorter sun rays that are now known to be curative and preventive of the faulty lime utilization designated under the term "rickets."

Pure quartz transmits these ultra-violet rays freely, and the General Electric Company by perfecting a method of producing sheets of clear quartz have given us window material of high transmissibility but, unfortunately for most of us, of very high cost. To meet this cost factor, less efficient window material has been devised by a number of firms, the products ranging from 60 per cent transmission when new, to all values less than 60 as compared with pure quartz. These panes still transmit enough rays to be clinically effective and are much less expensive than quartz, though at present considerably higher in price than ordinary window glass. It was soon found that by use these glasses lose to a degree their original transmission values, the change being designated as "solarization." The extent to which this change is possible becomes a factor in evaluating different market products in this field.

During the past eight months my laboratory has been engaged in testing the product of one of these glass manufacturers and also in conducting tests on the efficiency of an installation of the same glass

* Read before the Food, Drugs and Nutrition Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 17, 1928.

in a school building in a neighboring village. Before reporting the character and results of these tests I would like to review some of the information and unsettled points on the subject in order that the scope and significance of the tests themselves may be more apparent.

There seems to be general agreement among experts¹ that rays longer than 3,130 Angstrom units have little antirachitic value ($313\mu\mu$); * also, that while protective action is exhibited by rays shorter than $313\mu\mu$, and such rays are obtainable in artificial sources of ultra-violet light such as the mercury arc lamp or carbon arc lamp, the shortest rays that reach the earth from the sun are $290\mu\mu$ and, due to absorption by the atmosphere with its moisture, dust and smoke and the varying distance of the sun from the earth, sun radiation often contains none shorter than $300\mu\mu$. These facts prove that if we propose to use the sun as our source of protective ultra-violet rays and to strain it through window material, the latter's transmissibility of the rays from 313 – $300\mu\mu$ is what vitally concerns us. To show us that a window transmits rays below $300\mu\mu$ may be of importance if we are going to use artificial sources, but if the sun is to be our source, there will be no shorter rays to transmit. Similarly, transmissibility of longer rays than $313\mu\mu$ may tell us that the window is a better transmitter of illuminating rays, but these rays have no bearing on our seeking antirachitic power. These facts definitely delimit one criterion of selection in buying ultra-violet transmission material.

Today it is also generally agreed that there exists in our bodies and in certain foodstuffs a chemical substance designated as "ergosterol." Except in a few foods (the notable exception is cod liver oil), the ergosterol as it is found has no antirachitic power, but when it has been treated for a sufficient length of time to the action of the short rays (rays of $313\mu\mu$ – $253\mu\mu$ are now known to activate it), it becomes converted into what we call vitamin D and in this activated form controls the utilization of calcium in our bodies, prevents rickets and dental defects and generally supervises and adjusts our use of lime. When foodstuffs which contain the inactive ergosterol are irradiated with the short rays their ergosterol becomes vitamin D and the foods become antirachitic. When the body is irradiated with these short rays the ergosterol which is in our skin undergoes a similar activation, and after its probable absorption into the blood travels to the points where it protects us against rachitic troubles.

We may take cod liver oil with its already activated ergosterol;

* The length of light rays is usually expressed as millimicrons (a millimicron is one thousandth of a millimeter) or in Angstrom units (an Angstrom unit is one ten-millionth of a millimeter). Hence, in the literature a wave length may be given as $313\mu\mu$ (millimicrons) or $3,130\text{ \AA}$ (Angstrom unit abbreviation). In this paper we will use millimicrons as the unit abbreviated as $\mu\mu$.

we may eat irradiated foods with their activated ergosterol; or we may create this vitamin out of our own ergosterol by exposing ourselves to the short rays. In the last selection we must be sure that the rays reach the ergosterol in the skin, and their penetration power is very low, 1-2 mm. Clothing, dust and moisture absorb them.

Can a fully clothed individual, then, sit 6 or 8 feet from a short ray transmitting window and receive on his skin, most of which is covered by absorbing material, enough rays to do him any good? Must he sit in the direct path of the rays? Will reflected rays be of any value or are they wholly or in part absorbed when they strike the reflecting surfaces? These are practical queries, the answers to which determine: what rooms can be equipped to advantage with such window material; how to use them on baby and adult; and what care to give them to avoid nullification of value by films of dirt or moisture.

Does the mere presence of short rays of given length determine activity and protection? Marshall and Knudson² have recently confirmed by new experiments the evidence that intensity is quite as important as wave length. Using three wave lengths (302.2, 280.4 and 253.6 $\mu\mu$) they report that in small energy doses the effect is independent of the wave length but that prolonged irradiation may actually destroy the power that a shorter period has created. We must then have a certain intensity of irradiation. At certain seasons of the year the sun's rays may contain active waves ranging from 290-313 $\mu\mu$, but the intensity of these activating rays is widely different. Fabry and Boisson³ found at Marseilles that rays of 314.3 $\mu\mu$ were 750,000 times and rays of 302.2 $\mu\mu$ 90,000 times as intense as the shorter rays present in sunlight. Transmissibility to 290 $\mu\mu$ may insure full intensity of the available sun rays, but higher transmissibility of rays from 300-313 $\mu\mu$ might make a more practical window, range being in part compensated by intensity.

How many hours can a naked baby lie in front of a window in direct sunlight with benefit and without injury? Is the time the same in June as in December? Data given in a published address of Dr. Hess⁴ show typical seasonal and diurnal variations to be expected in the active rays of the sun. Hess shows that from December to February the amount of effective rays is much reduced and confined to a much shorter period of the day. The months when we need the windows most because of weather and temperature are those of least potent solar content. Bundesen and coworkers⁵ found comparatively little ultra-violet of physiological value in the sunlight of Chicago during the winter months. Tisdall and Brown,⁶ however, showed in Toronto that December sun contained enough to be protective of test

animals, and Fleming¹ in Washington, D. C., during December, 1927, and January, February and March, 1928, showed that not only was there enough of the rays present in the sunlight to protect test animals but that enough passed through Vitaglass, a typical window product, for this purpose.

This brief review is perhaps sufficient to explain the points which must be in mind in testing the efficiency of any sample of window material and to indicate the scope of the tests reported below.

Series I—To determine the efficiency of Vitaglass installation in a schoolroom in the vicinity of New York City during the months of January and February—This series of tests was conducted at the request of Superintendent of Schools Beattie of Bronxville, N. Y. Certain rooms having been equipped with Vitaglass windows, definite evidence as to their clinical efficiency was sought. Two of the rooms had almost identically the same exposure and differed only in the type of window glass, one being equipped with ordinary glass and the other with Vitaglass. In the Vitaglass room four cages of rats were distributed, one on the window sill in the direct path of the sun, one on a shelf on the window ledge but out of the direct path of the sun, a third on a shelf at the side of the room, and the fourth on a table at the back of the room. The other two cages were placed in positions in the ordinary window glass room corresponding to the first two locations given above. The rats in these cages were fed on Sherman-Pappenheimer² rickets producing diet No. 84. The installation was made on January 18, 1928, and the test was run for 30 days, ending February 16. It was felt that the positions of the rats corresponded to regions which pupils would occupy from time to time; that they would permit comparisons of indirect with direct light effects with and without Vitaglass; and that the clinical evidence of actual rickets prevention would be more convincing, if obtained, than mere data as to transmission and quantity of curative rays entering the room.

No evidence of protective action was obtained in any of the rats except the one directly in front of the window in the Vitaglass room. This rat was fairly well protected. None of the others in the entire period received enough curative rays to prevent acute rickets.

Series II—To determine whether in New York City during the period of spring in which schools are in session the atmosphere contains enough curative rays to be of significance—The Vitaglass Company was sufficiently interested in the evidence gained in the above test to ask that we conduct a series to settle the above point. A laboratory in the university, used by my department, has three windows facing south. The sashes of two of these windows were removed and

replaced by two Vitaglass panes each. By building a shelf in front of these three sashes on which to place rat cages, and by using screens to cut out cross rays (the set up is shown in the picture on page 1477) it was possible to measure the preventive action of transmitted rays through each of four panes of Vitaglass and through window glass as recorded by the rat occupants of these cages on a basal diet of rickets producing power (Sherman-Pappenheimer No. 84). Three 30-day tests were run. The first extended from about March 1 to April 1; the second from April 5 for a little over 30 days, extending through April into the first of May; the third series ran from May 20 to June 20. We were told that two of the Vitaglass panes were supposed to be solarized, but not which panes they were. In every series the rats received the direct rays passing through the south windows and, except for the windows, were protected from them only by the wire mesh of the sides and tops of their cages.

The first and second set of tests gave us protection for every rat in front of a Vitaglass pane, and the line tests on these rats did not permit differentiation between the four Vitaglass panes. Solarized and unsolarized glasses transmitted enough to prevent rickets. The controls before the window glass showed acute rickets.

During the third set of tests weather reports showed that there were less than 17 days of this period when the sun shone for 4 hours. This effect was evident in the line tests, for none of the four Vitaglass rats were protected though all showed a little more evidence of protection than the controls.

At the end of the third set of tests the panes of Vitaglass were removed from the sashes and sent to Professor Stockbarger of Massachusetts Institute of Technology, who tested their transmissibility to three wave lengths. The results are shown in Table I.

TABLE I
TRANSMISSIBILITY OF VITAGLASS PANES

Wave length	Pane No. 1	Pane No. 2	Pane No. 3	Pane No. 4
$\mu\mu$	Per cent	Per cent	Per cent	Per cent
297.0	29	23	10	15
308.5	51	44	29	36
320.0	70	65	54	59
Thickness	2.2 mm.	2.5 mm.	3.4 mm.	2.8 mm.

EXPLANATION OF CHART I—THREE SETS OF VITAGLASS TESTS

Protection against rickets is shown by the "line test." The drawings in the chart are camera lucida drawings of the split ends of rat knee bones. The narrowness of the "line" between the end of the bone and the shaft indicates degree of protection. The narrower the line the higher the protection. Set 1 was made in March, 1928; Set 2 in April, 1928; and Set 3 in May and June, 1928. The numbers 1, 2, 3, 4 indicate animals that were in front of "Vitaglass." The numbers 5 and 6 indicate animals that were in front of ordinary window glass. All animals were exposed for a period of 30 days.

CHART I

Discussion—These tests demonstrate that even with solarized glass, continuous exposure for 30 days admitted with these glasses enough active rays and intensity in New York City to be chemically efficient and clinically active. In combination with the first Bronxville series they demonstrate that with sufficient exposure in the direct path of the sun there is enough curative ultra-violet in these regions in January to April to be clinically effective even when screened by glasses which transmit half or less than half of the available supply.

The May-June result, with rainy weather, illustrates sharply one of the limitations of this system of irradiation.* It also shows clearly that weather may be quite as important a limiting factor as seasonal variation in solar content and intensity. While the series in any period failed to show marked difference between solarized and unsolarized or less solarized glass this does not justify indifference to this phenomenon. It does reassure us that in spite of solarization the glasses do not lose all efficiency even with transmission cut to 25 per cent for the curative rays.

These results speak favorably for the use of these glasses in New York City and vicinity in winter, but at the same time they should make it evident that the user needs specific data as to exposure time or he will be unable to intelligently apply this means of sun therapy. To merely install these glasses in the home, lay the baby in front of them for an hour a day, and assume that this is sufficient insurance against rickets is obviously taking too much for granted.

Series III—To determine whether in the school of Experiment I position of windows was a matter of importance—During April and into May three rooms in the Bronxville school were used in a further test: One room had western exposure, one eastern exposure (both provided with Vitaglass) and a third room with ordinary window glass and eastern exposure was selected as the control room. Two cages of rats were placed in each room, one in front of the window and one on a shelf out of the direct rays. For the period of exposure given, east or west showed no difference; protection of the window rat was complete if Vitaglass was used, and lacking with ordinary window glass.

* In response to inquiry by the Vitaglass Company, the following report was received from the Carnegie Institution of Washington, Mount Wilson Observatory, Pasadena, Calif.

"The following are the monthly averages of the ultra-violet (0.32μ) light in the sun for the dates you request

Feb 1928	1 28
Mar.	1 30
Apr.	1 30
May	1 20
June	1 22

You will note a general drop of about 7 per cent in May and June

"At 0.32μ the effect of complete cloudiness is ordinarily to reduce the intensity of sun plus sky to about 25 per cent of its value on a good clear day. During stormy weather it may drop to 15 per cent.

(signed) Edison Pettit "

VITAGLASS EXPERIMENTAL WINDOWS IN LABORATORY OF TEACHERS COLLEGE,
COLUMBIA UNIVERSITY

The shelf animals in the Vitaglass rooms got no protection.

Using a different method of measuring window efficiency, Janet Clark has⁹ recently reported and commented as follows:

A table of data obtained in this way on perfectly clear days at noon, during March, April and May, 1928, shows that although the intensity of ultra-violet irradiation increases from March to May, it is still necessary to sit about 15 hours at 5 meters from a north window of ultra-violet transmitting glass to get as much ultra-violet radiation as can be gotten by 2 minutes out of doors in direct sun at noon. . . . Any child going out of doors for recess, or any stenographer going out to lunch will get more ultra-violet radiation than she could get all day behind a window of ultra-violet transmitting glass. So although these materials have an undoubted field of usefulness in solariums, and probably in animal houses and zoos, it is unnecessary to put them in schools and offices where it would be cheaper and more efficient to send the individuals concerned out into the sunshine for a few minutes every day at noon.

Our tests are positive in showing that schoolrooms so equipped admit enough ultra-violet in winter months to heal or prevent rickets

CHART II

JAN. FEB. 1928 **1**

APRIL MAY 1928 **2**

EXPLANATION OF CHART II—SCHOOLROOM TESTS MADE IN BRONXVILLE, N. Y.

Series 1—The animals from which these bones were taken were placed in schoolrooms in positions similar to those that children occupied with the exception of No. 1, which was placed on the windowsill directly in the path of light. Specimens 1, 2, 3, 4 and 5 were all located in a room equipped with Vitaglass windows. Specimen 6 was in a room with similar light exposure but equipped with ordinary window glass. Note that during the period of exposure, from January 18, 1928, to February 16, 1928, the only rat in any way protected was No. 1, the rat directly in the path of the Vitaglass window rays.

Series 2—During May and June the tests were repeated at Bronxville with this modification. WE represents specimens from rats in a "western exposure" Vitaglass room. EE represents specimens from rats in an "eastern exposure" Vitaglass room, and in an "eastern exposure" ordinary window glass room, the right hand series being the Vitaglass room group and the middle series the window glass room group. The attached letters W, S and T indicate the position of the rat. The W specimen was on the windowsill in direct path of rays. The S and T rats were on shelf or table in same room but out of direct path of rays. Again only those animals in direct path of rays were protected and then only when in front of Vitaglass.

if weather is clear and exposure long enough; and that only that part of the room directly in the path of the rays receives this benefit. With these facts in hand it is for school boards to decide whether the benefits derivable justify the expense of installation. My own feeling is that schools and office buildings would invest their money more efficiently by equipping solaria, preferably with sky lighting and sex-segregated so that the needy cases could lie exposed for certain periods of the day to the full effect of the sun, with as little clothing as possible. I do see a place in homes and apartments for these glasses to permit mothers to save some hours of perambulation with the baby or chaperonage of small children.

The glasses are important inventions. It seems a pity to detract from their values and discourage their perfecting as aids to health by false claims or misdirected selling campaigns. Their purveyors will therefore do well to stress instructions as to where to install and how to use, rather than quantity sales, at least until the public is educated to their values and limitations.

Longevity of Typhoid Bacilli in Cheddar Cheese*

A Study Following an Outbreak of Typhoid Fever Traced to Cheese

E. M. WADE, FELLOW A. P. H. A., AND LEWIS SHERE†

*Divisions of Preventable Diseases and Sanitation, State Department of Health,
Minneapolis, Minn.*

CHEESE has been reported very rarely as a factor in the transmission of typhoid fever. The only prior epidemic of typhoid fever traced to Cheddar cheese that we have found is that which occurred in Michigan in 1917, and was reported by E. D. Rich¹ in 1923. In that epidemic there were 51 cases with 4 deaths. Two epidemics of gastroenteritis are reported by Linder, Turner and Thom,² a streptococcus pathogenic for cats being responsible; one was due to imported Albanian cheese and one to American Cheddar cheese.

During February, March and April of 1925, an epidemic of 29 cases of typhoid fever, with 4 fatalities, was reported from 8 sanitary districts of 4 counties in Minnesota. The first case developed symptoms February 2, and the last April 3.

Epidemiological investigations made by the department showed the source of infection to be cheese made in a coöperative cheese factory on January 11 and January 12. This cheese was noted by the cheesemaker as having what is commonly called "dead curd." The acidity of the milk could not be increased by any of the usual methods, and the result was a very soft cheese. As the creamery had many requests for fresh cheese, this lot was distributed as early as 10 days after making, instead of being held to ripen as is usually done.‡

The epidemiologist found evidence pointing to a carrier in the family of one of the contributing patrons of the cheese factory. Bacteriological findings confirmed this evidence. *B. typhosus* was isolated from 3 specimens of feces received from Mrs. B., age 57, who gave a history of having had typhoid fever in 1900.

* Read before a Joint Session of the Laboratory and Food, Drugs and Nutrition Sections of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 15, 1928.

† Resigned.

‡ On April 16, 1925, there was obtained, from one of the families in which typhoid fever occurred, a piece of cheese said to be part of this same lot. At this time, 95 days after manufacture, the cheese was very dry. The acidity was 0.95 per cent and no typhoid bacilli were isolated from it.

Cheese known commercially as Cheddar cheese is made from whole fresh milk. At this coöperative factory, the following method is used:

The milk is kept at a temperature of 86° F. until the acidity has reached 0.20 per cent. This is hastened by adding commercial starter. When the correct acidity has been reached, coloring matter is added and also rennet (4-6 oz. per 100 lbs. milk). The milk thus treated is allowed to stand without agitation until the curd is firm, at which time it is cut into small cubes and the temperature gradually raised (1° in each 5 minutes) to 98° F. The cubes of curd are gently but continuously agitated to prevent their adhering to each other, until they have shrunk to half their original size and when squeezed together by hand will not adhere. The whey is then drawn off and the curd stacked to drain with temperature maintained at approximately 98° F. The curd is turned every 15 minutes until the cheddaring process is completed, at which stage it has become a homogeneous mass of a texture like chicken breast, and when held for an instant against a hot iron forms shreds 1 to 1½ inches long. This cheddared curd is then cut up fine; salt is added (35 gms. to 100 lbs.), the temperature lowered to 80° F.; and the curd put into the cheese press. On removal from the press, the cheese is dipped in paraffine and stored at about 60° F. to ripen.

Since cheese so seldom has been found to be the source of typhoid epidemics, it was thought desirable to attempt to find out what kills typhoid bacilli in Cheddar cheese, as there seems to be nothing in the heat used or the acidity developed during the process of manufacture which would necessarily destroy these organisms. With this in mind, 18 small cheeses were made following as closely as possible the above method. A galvanized iron pan 15" x 10" in a water bath served for a vat, and a cutting implement was improvised from sheet metal.

For each cheese made, 7 quarts of milk were used. This milk was infected, usually the evening preceding the making of the cheese, with 50 c.c. of an 18-hour broth culture of *B. typhosus*. For all the experimental work, the typhoid strain isolated from Mrs. B. was used. The milk was allowed to stand over night either in the icebox or at room temperature, according to the age of the milk, maximum multiplication of the bacteria without curdling being desired. The finished cheeses weighed about ¾ lb. each and were of good consistency.

For the most part, one cheese was made on each of 3 successive days, using the same lot of milk, which was kept in the refrigerator until needed. Raw milk was used for all except cheeses O, P, R and S, for which pasteurized milk was used. Samples for examination for *B. typhosus* were taken at different stages during the process of manufacture, and at frequent intervals afterwards. After sampling the cheese by means of a cork borer, the hole was thoroughly sealed with paraffine. All samples were plated on 8 plates of brom cresol purple lactose agar, typical colonies fished, checked for cultural characteristics on broth, milk, dextrose and saccharose broth, and for agglutinability with known positive serum.

Samples were taken from each cheese during the process of manufacture as follows: (1) before adding the starter, (2) before adding rennin, (3) as curd was forming, (4) after cutting curd (both whey and curd), (5) on completion of cheddaring (both whey and curd), (6) after salting, and just before placing in press. Samples were taken from the finished cheeses daily, except from cheeses H and K, until three consecutive tests failed to show typhoid bacilli. On cheeses H and K bacteriological tests were made daily for 16 days and then at intervals of 3 or 4 days until the 36th and 34th days, respectively.

Tests for acidity were made daily on all but the first seven cheeses. For all acidity tests of cheese, 5 gm. were emulsified in a mortar with 100 c.c. hot water; 25 c.c. of filtrate were titrated with *N*/10 NaOH, using phenolphthalein as indicator. Table I gives a summary of the cheeses made, the length of time in days that *B. typhosus* was found living in each cheese, and the acidity of the cheese when 1 day old, and when *B. typhosus* was no longer found. All determinations have not been shown, as they would make the table cumbersome.

In each cheese tested the increase in acidity was gradual and *B. typhosus* was continuously present up to the date of first negative findings except in the following 5 instances: In cheeses B, C and E, one examination only failed to show *B. typhosus* before obtaining the

* No later tests, cheese all used.

† Last day of test, *B. typhosus* still present.

3 consecutive negative results. In cheese R one colony of *B. typhosus* was obtained on the 3d day while *B. typhosus* was not found on the 1st and 2d days, and in cheese U no typhoid bacilli were recovered on the 1st and 2d days, but not on the 3d to 8th days, inclusive.

With the exception of cheeses H and K the duration of *B. typhosus* ranged from 0 to 8 days, averaging about 4 days. The acidity ranged from 0.61 to 0.83 per cent when 1 day old, to 0.72 to 1.15 per cent at the end of the tests. From cheeses H and K, *B. typhosus* was recovered on every test until no more material for testing was left, which was on the 36th and 34th days after manufacture, respectively. Cheeses H and K had acidities of 0.67 and 0.47 per cent, respectively, when 1 day old. Cheeses L and P had practically the same degree of acidity as cheese H, yet *B. typhosus* survived in them but 3 days and 1 day, respectively. At the end of the testing, cheese H had an acidity of 1.04 per cent and cheese K only 0.72 per cent, and yet *B. typhosus* was surviving in both, while in 9 other cheeses in which typhoid bacilli could no longer be found, acidities ranged from 0.65 to 1.15 per cent. No difference was noted in the consistency of the cheese in which *B. typhosus* lived the longest and those in which *B. typhosus* was recovered for only a short period or not at all.

To determine what influence the addition of acid and the cultivation of certain organisms commonly found in milk have on the destruction of typhoid bacilli, the following experiments were undertaken.

Experiment I—January 5, 1926, 9 flasks of milk, each containing 800 c.c., were sterilized by steaming 1 hour on each of 3 successive days. Acidity of milk after sterilizing was 0.162 per cent. To each of 3 flasks enough chemically pure lactic acid was added to bring the acidity to 0.22, 0.58 and 0.99 per cent respectively. To 2 flasks pure culture of *S. lacticus* was added; 1 flask was kept at room temperature; and 1 in the icebox. To 2 other flasks a pure culture of a diplococcus isolated from pasteurized milk was added. (This diplococcus referred to hereafter as diplococcus X was an enzyme producer and had been causing sweet curdling of the milk in a large milk plant.) One flask was kept at room temperature and the other in the icebox. The remaining 2 flasks were used as controls. All 9 flasks were inoculated with *B. typhosus*, using for each flask 9 c.c. of an 18-hour broth culture. From time to time $\frac{1}{2}$ c.c. quantities from each flask were plated on brom cresol purple lactose agar, characteristic colonies fished and verified for *B. typhosus*.

The flask in which the acidity with lactic acid was 0.99 per cent curdled at once and *B. typhosus* was recovered on the 2d day, but not on the 3d day or later. From the flask in which the acidity with lactic

acid was 0.58 per cent *B. typhosus* was recovered for 37 days. In process of handling this flask became contaminated and the acidity increased until on the 24th day it was 0.83 per cent and remained unchanged until the 40th day, when the testing was discontinued. The flask in which the acidity with lactic acid was 0.22 per cent increased in acidity to 0.45 per cent by the 13th day and was 0.56 per cent on the 71st day. Tests were made at intervals of 4 or 5 days and *B. typhosus* was last recovered 84 days after inoculation. On the following day the acidity was 0.61 per cent.

The flask inoculated with *S. lacticus* and left at room temperature was curdled 4 days after inoculation but *B. typhosus* was isolated that day. The next test was made on the 7th day and no typhoid bacilli were found at that time or on three successive tests made at daily intervals. The acidity on the 8th day was 0.89 per cent. The corresponding flask in the icebox increased in acidity very slowly, reaching 0.40 per cent on the 105th day, and *B. typhosus* was recovered 163 days after inoculation, when testing was discontinued.

The flask inoculated with diplococcus X and left at room temperature increased in acidity slowly until it reached 0.60 per cent on the 30th day and then remained unchanged. *B. typhosus* was isolated 54 days after inoculation, but was not isolated on the 56th day or later. The corresponding flask kept in the icebox reached an acidity of 0.45 per cent on the 71st day after inoculation, at which time *B. typhosus* was isolated. Unfortunately, it was not tested again until the 105th day, at which time the acidity was 0.75 per cent and no typhoid bacilli were found.

The control flask inoculated with *B. typhosus* only, and left at room temperature, became infected during handling and the acidity gradually increased until the 34th day after inoculation, when it was 0.87 per cent. On that day *B. typhosus* was recovered, but on the following day and later no typhoid bacilli were found. In the similar flask kept in the icebox *B. typhosus* was isolated periodically for 163 days after inoculation, at which time tests were discontinued. On the 105th day the acidity was 0.52 per cent.

Experiment II—A similar set of tests was made on January 18, 1926. Milk was obtained from a certified dairy on January 13; 800 c.c. placed in each of 9 flasks and steamed 1 hour on each of 3 successive days. Three flasks were acidified with c.p. lactic acid to give final acidity of 0.53, 0.71 and 0.93 per cent respectively, instead of the weaker acid reactions used in the first experiment. Two flasks were inoculated with *S. lacticus* and two with diplococcus X. The remaining 2 flasks served as controls. One of each of the last 3 pairs

was kept in the icebox and the other at room temperature. The *S. lacticus* and the diplococcus *X* were grown in sterile milk and 10 c.c. inoculated into each of the respective flasks. To each of the 9 flasks was added 10 c.c. of an 18-hour broth culture of *B. typhosus*.

The flask of milk made 0.93 per cent acid with lactic acid was tested daily and *B. typhosus* was recovered after 2 days but not on the 3d day or later. The milk made 0.71 per cent acid with lactic acid continued to show typhoid bacilli for 8 days after inoculation, but no typhoid bacilli were found later. The acidity tested on the 6th and 10th days was 0.70 per cent. The milk acidified to 0.53 per cent with lactic acid remained at that acidity for 22 days. On the 25th day, the acidity had increased to 0.78 per cent and a growth of small acid producing colonies appeared on the plates in addition to the typhoid colonies. *B. typhosus* was last isolated 30 days after inoculation, but only 5 days after acidity was found to have reached 0.78 per cent, and at most 8 days after acidity rose above 0.53 per cent.

The milk inoculated with *S. lacticus* and left at room temperature increased rapidly in acidity, daily readings for the first 5 days being 0.45, 0.68, 0.77, 0.81 and 0.84 per cent respectively. *B. typhosus* was isolated daily for 5 days but not on the 6th day or later. The similar flask of milk kept in the icebox increased slowly in acidity, reaching 0.65 per cent 27 days after inoculation, at which time *B. typhosus* was last isolated. The flask of milk inoculated with diplococcus *X* and left at room temperature increased in acidity slowly at first, reaching 0.55 per cent on the 16th day. Then the acidity increased rapidly, to 1.04 per cent, 34 days after inoculation, at which time *B. typhosus* was recovered. On the following day and later no typhoid bacilli were found. The similar flask kept in the icebox increased gradually in acidity, reaching 0.62 per cent on the 60th day and 0.88 per cent on the 90th day. *B. typhosus* was isolated on the 86th day after inoculation, but not on the 92d day or later.

In the control flask inoculated with *B. typhosus* only and left at room temperature the organisms survived 129 days after inoculation and in the one in the icebox 151 days, when tests were discontinued.

Experiment III—Four flasks of milk, sterilized as in the previous experiment, were acidified January 25, 1926, with lactic acid to make the final readings 0.74, 0.78, 0.81 and 0.90 per cent acid, and then inoculated as before with *B. typhosus* and tested daily. *B. typhosus* was recovered after 1 day only from the milk made 0.90 per cent acid and after 4 days from each of the other 3 flasks.

It appears from these three experiments with milk that an acidity of about 0.70 per cent continued for a few days is deleterious to ty-

phoid bacilli, but in 1 flask of milk in the first experiment, *B. typhosus* survived an acidity of 0.80 per cent for 13 days and in the second experiment an acidity of 0.92 to 1.04 per cent for 7 days. In the first case an acid producing organism was growing in the milk and in the second case an enzyme producer had been cultivated along with the typhoid bacilli.

From these tests it seemed probable that the type of bacteria growing in milk or cheese had an influence on the length of life of *B. typhosus*, either through some undetermined chemical change or through the kind of acid produced. Since it was not practicable to test the various flasks of milk and the cheeses for all the acids present, it was decided to test the longevity of *B. typhosus* in the presence of the different acids commonly found in cheese—lactic, butyric, acetic, propionic, and caproic. For this test 16 flasks were prepared each containing 600 c.c. sugar free broth pH 7.2. It was planned to use 1 flask for control and 3 flasks for each acid, sufficient acid to be added to make acidity titrated with *N*/10 NaOH read 0.70, 0.85 and 1.00 per cent, respectively. The available supply of propionic and caproic acids was insufficient to procure quite the concentration of acidity desired. After the reactions were adjusted *B. typhosus* was added, using 8 c.c. of an 18-hour broth culture for each flask. Plates and subcultures were made daily until at least two consecutive sterile tests were obtained. The actual titrations and results are given in Table II.

These tests show a striking difference in the effect of different acids and indicate that caproic acid is much the most detrimental to *B. typhosus*, as this organism does not survive a concentration of 0.70 per cent for 1 day, whereas it survives acetic acid in a concentration of 0.73 per cent for 4 days and of 1.00 per cent for 1 day.

The shorter life of the typhoid bacilli in broth to which lactic acid is added, than in milk with the same percentage of lactic acid, is probably due to the combination of some of the lactic acid with the casein, there being left only a portion of the total acid free to act upon the organisms, as pointed out by Zae Northup^{*} in a study of the influence of the products of lactic acid on *B. typhosus*.

In order to determine the effect of diminution of free access of air on the life of *B. typhosus* in cheese, the following experiment was undertaken:

On April 1, 1926, cheeses L, M and N, which had been made February 23, 24 and 25, respectively, and from which *B. typhosus* no longer could be recovered, were ground in mortars. To 50 gm. of each cheese was added 10 c.c. broth culture *B. typhosus*, and the whole emulsified. Instead of putting in presses, these samples were left at

room temperature in tumblers, covered with glass Petri plates and tested daily for *B. typhosus*. The samples, of course, became very mouldy but *B. typhosus* was isolated for 16 days from one sample and for 13 days from each of the others. The acidities of the cheeses before emulsifying were 1.15, 1.19 and 1.04 per cent, respectively. Table III shows the changes in acidity and the bacteriological findings on the daily tests.

The remainder of cheeses L, M and N was mixed and emulsified with *B. typhosus* broth culture, using 450 gm. of cheese and 100 c.c.

of culture. This emulsion was then packed in the cheese press, at which time the acidity was 0.97 per cent, and when removed from press the following morning the cheese mixture was dipped in paraffine. Samples were taken daily by means of a cork borer. *B. typhosus* was recovered for 7 days only. At the beginning of the tests the acidity of the mixture was higher for some unexplained reason than that of the individual samples, and the shorter length of life of *B. typhosus* may have been due to the acidity rather than to the partial exclusion of air. However, the sample of cheese L emulsified and left in the tumbler developed an acidity of 1.12 per cent by the 9th day and *B. typhosus* lived for 6 days thereafter, whereas the acidity of the mixture of the three cheeses at no time exceeded 0.98 per cent. The variation in the type of bacteria multiplying under the two conditions may also have had an influence on the survival of the typhoid bacilli.

This investigation has raised many questions that need further study, both from a chemical and from a bacteriological point of view.

SUMMARY AND CONCLUSIONS

1. Reference is made to an epidemic of typhoid fever traced to Cheddar cheese made at a factory, one of whose contributing patrons was proved to be a typhoid carrier.

2. The cheese in question had been made from milk which would not curdle satisfactorily. This would indicate an unusual bacterial flora resulting in a changed chemical condition.

3. The development of cases in the epidemic indicates that *B. typhosus* lived in the cheese approximately 63 days.

4. Eighteen experimental lots of cheese made from milk infected with *B. typhosus* contained the organisms on the day of manufacture.

5. The experimental data indicate that usually, in the ordinary course of ripening, *B. typhosus* cannot be recovered from Cheddar cheese after the 8th day. However, 2 of the 18 cheeses harbored *B. typhosus* for 34 and 36 days, respectively.

6. Since the two cheeses in which *B. typhosus* lived 34 and 36 days, respectively, were made from the same lot of milk, it is probable that the longevity of *B. typhosus* in Cheddar cheese is influenced by the bacterial flora of the milk. Two instances in the milk experiments gave comparable results and seem to substantiate the same probability.

7. The experimental data indicate that the degree of acidity and the character of the acid present are important factors in the destruction of *B. typhosus* in cheese. However, a specific acidity will not uniformly result in the destruction of this organism in cheese. This is probably because different acids do not affect the organism to the same degree and also because the bacterial flora of the milk and the complex chemical constituents of cheese may counteract the effect of the acidity differently in different lots of cheese.

Geographic Distribution of Deaths from Diphtheria*

DONALD B. ARMSTRONG, M. D., FELLOW A. P. H. A., AND GEORGE H. VAN BUREN, FELLOW A. P. H. A.

Assistant Secretary, Welfare Division, and Supervisor, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

AN attempt has been made to study the geographic distribution of diphtheria deaths during the last two years (1926 and 1927) based primarily upon records of the industrial policy holders of the Metropolitan Life Insurance Company. During 1927 there was an increased prevalence of diphtheria which, except for limited areas, appeared to spread quite generally over the United States and Canada. The extent of this increase, so far as the Metropolitan experience is concerned, is indicated in Table I.

TABLE I

DEATH RATES PER 100,000 FROM DIPHTHERIA. METROPOLITAN INDUSTRIAL POLICY HOLDERS AND U. S. REGISTRATION STATES, AS OF 1910. TOTAL PERSONS, ALL AGES

Year	Metropolitan	U. S. Reg. States, as of 1910	Year	Metropolitan	U. S. Reg. States, as of 1910
1927	10.6	*	1918	19.3	14.7
1926	9.7	7.4	1917	24.6	16.5
1925	10.6	7.9	1916	21.0	13.9
1924	13.1	10.4	1915	21.4	14.5
1923	15.5	12.9	1914	25.7	17.2
1922	18.0	14.4	1913	27.2	18.2
1921	23.8	17.7	1912	24.5	16.9
1920	22.1	15.9	1911	27.3	17.9
1919	20.9	15.9			

* Not yet available.

It will be observed in the Metropolitan experience that the consistent decline year by year since 1921 from the high point of 23.8 was broken in 1927, when the rate of 9.7 for 1926 was succeeded by an increase to 10.6 per 100,000. This table also indicates the diphtheria rates from 1911 to 1926 for the U. S. Registration States, the 1927 figures not being, as yet, available. In all probability, however,

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 19, 1928.

the 1927 rate will show a material increase for the registration states over 1926. We have, in fact, an estimate made by the Surgeon-General of the U. S. Public Health Service, reported to us by the Health Department of Virginia, in which preliminary reports for 1927 for the U. S. Registration Area indicate an increase in diphtheria deaths of approximately 17 per cent over 1926.

Another indication of the increase in diphtheria in 1927 is to be found in the American Medical Association report on diphtheria mortality.¹ Table II presents certain figures from this report:

TABLE II

DIPHTHERIA DEATH RATES PER 100,000 POPULATION IN CERTAIN STATES AND IN URBAN AREAS BY GEOGRAPHICAL DIVISIONS, 1926 AND 1927

	1927	1926
Colorado.....	9.1	9.2
Maine.....	+ 3.8	2.5
Maryland.....	+ 7.4	6.2
Massachusetts.....	+ 6.3	5.9
Minnesota.....	3.0	5.9
Montana.....	+ 2.8	2.6
New York.....	+ 8.6	6.4
Pennsylvania.....	+ 8.5	8.3
Wyoming.....	4.6	5.5
Cities in:*		
New England.....	+ 8.8	6.8
Middle Atlantic.....	+ 11.8	9.2
South Atlantic.....	+ 7.5	6.4
East North Central.....	+ 13.3	12.8
East South Central.....	+ 7.6	6.8
West North Central.....	5.6	10.0
West South Central.....	+ 11.2	7.8
Mountain and Pacific.....	5.9	7.2

* Cities of 100,000 population and over

It will be noted that for the 9 states for which figures were available at that time, all but 3 showed varying but, for the most part, small increases in rates. The 3 showing decreases (Colorado, Minnesota, and Wyoming) are all western or northwestern states. For the cities over 100,000 population, grouped by geographic grand divisions, there are increases recorded except in the Mountain and Pacific Group and the West North Central Group (cities in Minnesota, Iowa, Nebraska, Kansas and Missouri).

Ordinarily, such a small rise in the mortality from *any* disease would be in nowise disconcerting. But, in the case of diphtheria, it may be of decided importance for the following reason: For each of the 5 years immediately preceding 1927, a new minimal diphtheria death rate was in evidence. During this continuous decline the diph-

theria mortality rate among Metropolitan industrial policy holders dropped 60 per cent, and in the registration area 58 per cent. This continuous decrease is considered one of the outstanding public health accomplishments of the current decade. It was naturally expected to continue as the period was contemporaneous with an increasingly intensified campaign for immunization of children against diphtheria—and, to our knowledge, there was no relaxation in that campaign during 1927. We regard even this small increase in the diphtheria death rate as an important point of inquiry for the public health workers of America, to determine where the increase has occurred, and more particularly, the relative relationship of those localities where immunization campaigns have been especially active and persistent.

A more detailed analysis of the Metropolitan experience, based on total mortality figures, and not rates, discloses the following facts: In 1926 in this group of more than 18,000,000 industrial policy holders, there were 1,689 deaths from diphtheria; in 1927 there were 1,884 deaths—an increase of 195 deaths, or 11 per cent. This increase is materially in excess of the increase in numbers of policy holders, as demonstrated by the rate increase in Table I.

For business, administrative, and statistical purposes, the Metropolitan field work is organized on a territorial basis. When the diphtheria experience for these 2 years is analyzed according to territories, it is found that certain territories (5 in number) have more or less marked increases, while others, not listed below, remain practically stationary, and 2 territories show decreases. The striking increases are as follows:

	Increase
Metropolitan Territory (including Greater New York and Westchester County)	193 to 256
Middle West Territory (Illinois and Indiana)	149 to 185
Keystone Territory (Pennsylvania)	151 to 172
Atlantic Coast Territory (Delaware, District of Columbia, Maryland, New Jersey and Virginia)	123 to 196
Canadian Territory (8 Provinces including Quebec)	185 to 259

The 2 territories showing decreases are as follows:

	Decrease
Northwestern Territory (Iowa, Michigan, Minnesota, Nebraska and Wisconsin)	218 to 153
Pacific Coast Territory (California, Colorado, Idaho, Montana, Oregon, Utah and Washington)	136 to 104

A further analysis of certain of these increases, particularly in the Metropolitan and Middle West Territories, discloses data of interest. The Middle West, increasing from 149 to 185, is made up of 2 states, 1 of which, Indiana, showed a decrease from 32 to 22, while Illinois jumped from 117 to 163. Further analysis indicates that this in-

crease was entirely confined to Chicago. The number of deaths in Chicago in 1927 increased over 1926 from 84 to 136—an increase of 52, or 62 per cent. In the rest of the state there was actually a decrease from 33 to 27 or an improvement of 18 per cent.

If a parallel contrast is drawn between the Metropolitan Territory (New York City and environs) and New York State, comparable and similar observations result. In the Metropolitan Territory the increase was from 193 to 256, an increase of 63, or 33 per cent. In New York State, exclusive of New York City, the increase was from 60 to 63—3 deaths, or 5 per cent. The increase for the state and city combined was 26 per cent.

From this analysis it would appear that in these 2 territories, showing marked increases, the augmented diphtheria mortality was an urban affair. As a matter of fact, combining the increase for New York City and Chicago gives a total of 115 deaths, or 59 per cent of the total increase in the Metropolitan experience. Still further contrasting this urban and rural picture, the combined mortality for the 4 cities showing the highest increases in the Metropolitan experience (New York, Chicago, Pittsburgh and Montreal), approximates 88 per cent of the total increase (172 deaths).

It seems probable that a further analysis of the registration area figures, when they are available, will support this rural-urban contrast. This is borne out by such information as is now obtainable. Data for both cases and deaths for 1926 and 1927, for the general population of New York City and for the rest of the state, are given in Table III.

TABLE III

DIPHTHERIA CASES AND DEATHS, 1926 AND 1927—NEW YORK CITY AND REST OF NEW YORK STATE

	1926	1927	Increase	Per Cent Increase
City { Cases	7,800	13,507	5,707	73.2
{ Deaths	477	717	240	50.3
Rest of State { Cases	3,628	3,914	286	7.9
{ Deaths	251	265	14	5.6

From this it will be observed that in the city cases increased 73.2 per cent, whereas in the rest of the state the increase was only 7.9 per cent. Deaths increased 50.3 per cent, whereas upstate the increase was but 5.6 per cent.

Data furnished by Dr. Rawlings of Illinois, contrasting Chicago with the rest of the state, bring out the same picture:

TABLE IV

DIPHTHERIA CASES AND DEATHS, 1926 AND 1927—CHICAGO AND REST OF ILLINOIS

	1926	1927	Increase	Per Cent Increase
Chicago { Cases	2,551	4,124	1,573	61.6
{ Deaths	224	442	218	97.3
Rest of State { Cases	1,978	2,148	170	8.6
{ Deaths	186	205	19	10.2

It is noted that in Chicago cases increased 61.6 per cent, whereas in the rest of the state the increase was but 8.6. Deaths increased 97.3 per cent, whereas in the rest of the state the increase was but 10.2.

A further glance at the Company territorial decreases discloses the fact that in the Pacific Coast Territory the decrease was more or less general throughout the states and sub-divisions. This corresponds with the experience of the general population as indicated in the data presented in Table II. As shown in that table, the only states showing decreases and the only groups of cities showing decreases, except those in the West North Central section, are Mountain or Pacific states and cities.

The other territory showing a decrease was the Northwestern Territory. When this decrease is analyzed by states, the only striking contrast is that of Michigan where the decrease was from 149 to 99. If the experience of this state is further analyzed, it is found that an essential part of this decrease was in Detroit (from 108 to 79, or 29 per cent). This decrease represents 58 per cent of the total state decrease and 45 per cent of the total decrease for the entire Northwestern Territory.

Is it possible to hazard any surmises as to the etiological factors in this picture? We of course do not know how many or what factors may have been responsible for the increased mortality that affected large portions of the country, and that obviously were especially manifest in the very large centers of population. Why did the outbreak of 1927 apparently especially affect the large cities? Why was it essentially, so far as our records go, an urban affair? Does this condition reflect, probably among other influences, contrasts in relative percentages of immunity on the part of the childhood population? It must be remembered that the areas referred to as "rural" are so only by contrast to the great metropolitan areas. They contain, of course, small towns and cities.

There would seem to be some evidence to indicate that the prob-

able percentages of population immune as a result of the relative effectiveness of recent efforts at immunization, may be a factor in these contrasts. Taking New York State and City, for instance, it is a well-known fact that during the last 2 years at least, immunization with toxin-antitoxin has been more extensive upstate than in the city. In New York City the Health Department figures indicate a total of 30,024 children immunized by the department in 1926, and approximately 82,000 immunized in 1927. Of course, it is recognized that many of those immunized in 1927 would not have developed their immunity sufficiently early to combat the epidemic of that year. Nevertheless, the total of 112,024 immunized in the 2 years indicates the volume of work done. This can be measured against a general estimated population of 5,970,000. It does not, of course, include immunizations by private physicians.

In contrast, in the upstate area, the Health Department has a record of 118,220 children immunized in 1926 and 211,013 in 1927, or a total of 329,233 against an estimated population of 5,495,000. It is generally conceded that during the last two or three years in the upstate area, more immunization work has been done; a larger percentage of preschool children has been reached; and more work in particular has been carried out in the small town and semi-rural areas. The evidence would be more convincing if there were available reliable estimates as to the actual percentage of the childhood population now immune in these 2 areas.

Figures for Chicago and the rest of Illinois apparently indicate the same tentative conclusions. The State Department of Health *Monthly Bulletin* for May may be quoted as follows:

Leaving Cook County out of consideration, Illinois experienced its lowest loss from diphtheria last year. Forty-four counties escaped without a single death from this cause and the loss suffered by the others amounted to 150 fatalities compared with 160 in 1926. This amounted to a 6 per cent decline in the number of deaths, and gave a rate of 3.9 per 100,000 population. In 1926 the rate was 4.3 for the state outside Cook.

Including Cook County the state suffered an increase of 57 per cent in mortality from diphtheria during 1927. There were 30 counties in which increases were observed but the rise of 98 per cent in Cook County was by far the most important factor in making the state average greater. . . .

While no very accurate analysis of the data has been made it appears certain that the use of toxin-antitoxin has been promoted on a much larger scale in the northern and southern counties than in the central section of the state. Work in the southern territory has been particularly noticeable, and apparently it has appealed to the public there in a more practical way than elsewhere. In a number of communities toxin-antitoxin has been given to practically the whole susceptible population. Doubtless this has been an important factor in the favorable experience with diphtheria.

We previously pointed out that the decrease in the Northwestern Territory, and particularly in Michigan, was to be accounted for largely by the decrease in Detroit. While definite statistical conclusions cannot be drawn from the experience there, the general impression of health authorities in that city would seem to reflect the foregoing observations as to the apparent relative protection resulting from a notable if not unique urban immunization effort in that city.

A report furnished by Dr. Buck of the Detroit Health Department indicates that during 1926 and 1927, 144,691 children were immunized, which brings the total immunized in that city since 1921 up to 181,294, measured against an estimated population in 1927 of

TABLE V

DIPHTHERIA—NEW YORK STATE EXCLUSIVE OF NEW YORK CITY

	Per 100,000 Population		Per 100 Cases
	Case	Death	Fatality
1920.....	190	18.8	9.9
1921.....	250	17.0	6.8
1922.....	161	12.4	7.7
1923.....	111	8.8	7.9
1924.....	127	8.2	6.4
1925.....	92	7.2	7.8
1926.....	69	4.7	6.8
1927.....	78	4.9	6.3
1928.....	63	5.0	7.8

1,334,500. Even when corrections are made for overlappings and graduations from one age group to another, it is estimated that the percentage of children under 11 years now immunized in Detroit is approximately 57—the highest recorded percentage for any large city, so far as we know.

Another state which has a rather unusual record in immunization work within the last 2 years is Virginia. During the latter part of 1926 and early part of 1927, 200,000 children were immunized in Virginia at clinics organized by the State Department of Health. The department estimates that at least 40 per cent of the childhood population of Virginia has been protected, and believes that this has had a very determining influence in effecting a decline of 20 per cent in the death rate, and 38 per cent in the case rate from diphtheria during the last year.

The foregoing observations on New York, Illinois, Detroit and Virginia, while not conclusive, are nevertheless decidedly encouraging

in reflecting, as they apparently do, the protection which relatively extensive immunization gave the childhood population against a practically nation-wide increase in the disease.

The only records we have immediately available for 1928 are the Metropolitan industrial policy holders' figures and the records for up-state New York. So far as the Metropolitan experience is concerned, the wave of diphtheria characterizing 1927 seems to a degree to have persisted during the first half of 1928. On September 22, however, the cumulative rate for 1927 was 9.2 per 100,000, whereas on the same date in 1928 it was a fraction below the 1927 figure. The tendency has been in the direction of a lower rate and it is hoped that the 1928 figure may fall still further below the 1927 record.

In New York State, exclusive of the City, the number of cases reported in 1928 was slightly below the 1927 figure for the first half of the year. The fatality rate is, however, somewhat higher, making the death rate approximately the same. Figures from 1920 to 1928 inclusive, comparing the first half of these years, are given in Table V, as prepared by the New York State Department of Health.

What is needed in the campaign for diphtheria prevention is a more intensive and effective effort to immunize a large percentage of the childhood population, to reach a relatively much greater percentage of preschool children, and to carry out the program at least as effectively and extensively in the great centers of population as has been demonstrated to be feasible in the smaller population areas. Furthermore, the 1927 experience, as implied previously, seems to constitute a problem worthy of further study and analysis by interested health agencies.

The Industrial Viewpoint of the Phenol Waste Disposal Problem*

FRANK F. MARQUARD, C. E., M. E.

Carnegie Steel Company, Clairton, Pa.

MY first experience with phenol contaminated waste waters polluting the streams dates back to 1906 when we had a complaint from the New Castle, Pa., Water Works, located on the Shenango River about 20 miles south of Farrell, Pa.

We had 212 by-product coke ovens at Farrell which began operating in 1903 and were dismantled in 1923. We made no effort to treat the phenol water from this plant for the first three years of operation. The taste in the river water was pronounced only occasionally, usually in the winter after ice had covered the river and prevented oxidation.

After extended investigations it was concluded that this water could not be treated commercially with sufficient assurance of removing all the taste producing acids, so that it would be clean enough to put into the river. Very accurate records were kept on the taste of the water supply of New Castle, as the taste was occurring too frequently.

In 1906, Dr. Unger, of the Research Bureau, of the Carnegie Steel Company, came to Farrell and conducted a series of tests but could not find any practical solution for our trouble. It was then that I suggested the use of this contaminated water for quenching our coke and for the building of a return quenching system. Only about 20 per cent of the water which is put upon the hot coke is evaporated and the rest runs off the coke as hot contaminated water; so we had to construct large sumps to keep this return contaminated water from entering the sewer. This opened up another problem, for this returned waste water was polluted with fine coke dust. In order to get a maximum settling we were obliged to construct large settling basins; but even with these we found that a considerable amount of fine coke dust was carried along into our circulating pumps and cut out our impellers so rapidly that we were forced to re-design our centrifugal pumps to reduce this excessive abrasion of the impellers. We also discovered that the rapid circulating of the returned quenching water heated the water to almost a boiling temperature, so that we lost the

* Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 18, 1928.

suction of our pumps, necessitating the lowering of these circulating pumps to a level assuring us a constant suction head of at least 5 feet.

The rapid accumulation of coke dust in our sumps necessitated the development of a means for removing this dust without stopping the quenching operation. We found that the best way to clean out these sumps was by the use of a locomotive crane and clam shell bucket which lifted out the dust without emptying the water from the sump.

These sumps were subsequently designed with a capacity sufficiently large to allow at least a carload of coke dust in the settling compartments and of such dimensions that a locomotive crane operation could be efficiently used.

We also found that in order to have a uniform quality of quenching water it was necessary to have all of our contaminated waste waters led to one central mixing tank and any make-up fresh water that was required would be added to this central mixing tank. This latter development was applicable to a larger sized plant, such as we now have at Clairton, Pa., where there are 10 quenching stations. The Clairton By-Product Coke Plant has a daily coking capacity of 30,000 net tons of coal per day.

The Clairton plant is located several miles above the McKeesport City water intake, and it was imperative that this river water, because it had practically no opportunity of purifying itself by stream oxidation, be free from phenol pollution.

Thus having worked out the mechanical arrangement to handle this contaminated waste water, with a closed quenching system at each quenching station, we were certain that we could evaporate all of our contaminated waste waters by the quenching of the hot coke. It was discovered, however, that the phenol in the waste waters was not so much the cause of any great trouble around our plant, but because of the large amount of chlorine on our coal, our ammonia still waste waters were heavily charged with calcium chloride, which was formed in our ammonia stills by the use of milk of lime to free the ammonia from the ammonium chloride. It is this calcium chloride, which builds up to 2½ per cent in the quenching waters, that has given us the greatest amount of trouble, due to its corrosive nature.

The quenching machines, rails and steel work around the batteries, and in fact all over the plant, are subjected to an abnormal rusting action, for the steam generated in the quenching operation carries a considerable amount of calcium chloride mechanically, and sprays the corrosive vapor over wide areas.

While we have solved the problem of the disposal of this taste producing contaminated waste water, as far as preventing its dis-

charge into the stream, it has not been in a manner that will eliminate a source of great expense and plant atmospheric nuisance.

We find a very pronounced odor to the coke quenched by this contaminated water, and while this odor does not affect the use of this coke for metallurgical purposes, it does interfere to some extent with its sale for domestic use, and the calcium chloride, being hygroscopic, makes it difficult to secure the low moistures in the coke secured by fresh water quenching. The excessive corrosion from the quenching with the calcium chloride water may be caused by the formation of some free hydrochloric acid.

For a good many years, we have been working on the problem of economic recovery of the phenols from the ammonia still waste, and recently considerable progress has been made; in fact, some plants have secured an efficiency of 90 to 95 per cent removal, and with this degree of refinement it is possible to discharge treated effluent into the streams at such a dilution that no taste trouble will occur.

The large percentage of by-product coke plants of this country are built with direct system of ammonia recovery. By this means the average coals will produce 20 gallons of ammonia still waste per ton of coal coked. This water comes from the free and fixed water in the coal. Plants using washed coal with a free water content of 8 per cent and 5 per cent fixed water will have about 28 gallons of ammonia still waste per ton of coal; while plants using the indirect system of ammonia recovery will have about 90 gallons per net ton.

Since the evaporation by hot coke quenching requires 70 to 80 gallons of water per net ton of coal coked, it is apparent that by the use of the indirect system of ammonia recovery we will produce about 10 per cent more still waste from this source alone than can be evaporated by the coke produced. But in the direct ammonia recovery system, such as we have at Clairton and in about 80 per cent of the by-product coking capacity of this country, it is possible not only to evaporate all of the still waste produced, but an additional amount of 60 gallons per net ton of coal coked; so that we are able to take all of the benzol plant contaminated waste water, in addition to all of the final direct cooler water, as well as all of the ammonia still waste.

Table I shows the amount of contaminated waste water coming from the three principal sources of a by-product coke plant of the direct ammonia recovery system and complete benzol recovery and refining operations; also the analysis of the contaminated water from each of these three sources.

From these figures it is apparent that a coke plant produces some contaminated waters which are practically free from phenols, such as

TABLE I

CONTAMINATED WATER DISPOSED OF DAILY BY CLAIRTON BY-PRODUCT COKE PLANT
Capacity of Plant 30,000 N. T. Coal per 24 Hours

Contaminated Water	Gals. Per Day	Gals. per Net Ton Coal	Contamination	Method of Disposal	Remark
Still Waste	600,000	20	Phenols, Cyanides, Tar and CaCl_2	All used for coke quenching	No connection to sewer
Benzol Sump	300,000	10	Benzol, Wash Oil and Naphtha	Recirculated	"
Final Cooler	1,500,000	50	Phenols, Cyanides, Tar and Naphtha	Recirculated and excess used for quenching	"

Total water evaporated—2,400,000 gallons

ANALYSIS OF CONTAMINATED WATER

Still Waste		Benzol Sump Water		Final Cooler Water	
	GPL		GPL		GPL
Phenols	2.00	Benzol	2.00	Phenols	0.28
Cyanides	0.50	Wash Oil	4.00	Cyanides	0.10
Tar Oils	1.00	Naphthalene	0.50	Tar Oils	0.30
Calcium Chloride	16.00			Naphthalene	1.00

the 10 gallons per ton of coal coming from the benzol plant; these waters are contaminated with benzol, wash oil and naphthalene, so that in either case, whether the phenols are extracted or not, the remaining source of taste producing contaminated waters may be objectionable for discharge into the streams and should be evaporated by hot coke quenching in a closed quenching system.

I might mention that the Clairton By-Product Coke Plant is not only the largest plant of its kind in the world, but it is operating on 100 per cent high volatile Pittsburgh coals, containing a high percentage of tar and very high chlorine content. Our frequent checking system by sampling indirect condenser water for tastes enables us to discover the slightest leaks from our condensers; permitting us to operate this large by-product plant full capacity for the past 10 years, without discharging any phenolated waste waters into the stream.

Some day it may develop to be a profitable operation to extract the phenols from the ammonia liquor so that this liquor free from phenols can be put into the streams. In this event, a very large amount of corrosion coming from the calcium chloride could be eliminated, as the calcium chloride free from phenols may be disposed of in the streams. The remaining source of phenol and benzol contaminated water could continue to be used as quenching water, and evaporated.

NOTE: W. L. Stevenson, Chief Engineer of the Sanitary Water Board of the Health Department of the State of Pennsylvania, has given untiring effort and coöperation, and the Carnegie Steel Company officials, as well as all of those associated in the Clairton operation, have spared no expense in their efforts to obtain a satisfactory solution of this most perplexing problem in the by-product coking operations.

Common Interest Problems of State Directors of Public Health Nursing*

EVA F. MACDOUGALL, R. N.

*Director, Division of Public Health Nursing, Indiana State Board of Health,
Indianapolis, Ind.*

IN Indiana we try to serve all groups of public health nurses, those employed by unofficial as well as by official health agencies. This means that school nurses, tuberculosis nurses, city health department nurses, bedside or visiting nurses, and industrial nurses come under our observation. The only other advisory nurses in the state are a nursing field representative employed by the American Red Cross and two district advisory nurses, one employed by the Metropolitan Life Insurance Company and the other by the John Hancock Life Insurance Company.

In our relation to these groups of nurses, the most important problems confronting state directors are:

1. To get the right nurse in the right position. Placement work is one of the most important tasks of a director. It enables her to insure the right standards of public health nursing in a service from the beginning.

2. To maintain good nursing technic. Since the nurse is a teacher, and her every nursing procedure is usually carefully observed by imitative children or adults, she cannot afford to be lax on this score, even though the fundamental principles of asepsis were not involved.

3. To make sure that the nurse's visit shall be packed with sound education. For instance, advocating more home calls to a school nurse means nothing if she only steps to the door and tells a mother that her son's tooth is decayed and then departs. There is a scientific plan for the essential content of a home nursing visit which the nurse must understand thoroughly.

4. To see that the nurse knows how to form her program in a systematic manner to meet the needs of her community, instead of proceeding each day without any preconceived plan.

5. To make sure that the nurse closely adheres to her medical ethics. There is no type of nursing which taxes a nurse's knowledge of medical ethics and judgment in practicing it, as does public health nursing, where in the daily round of her duties she comes in contact with the patients of not only every physician in the community but of every quack as well.

6. To see that a nurse knows how to mobilize and utilize voluntary assistance, that great storehouse of energy and means of wider activity and publicity for her and her work, if rightly used and directed.

* Read before the Public Health Nursing Section of the American Public Health Association at the Fifty-seventh Annual Meeting at Chicago, Ill., October 15, 1928.

7. To see that the nurse understands how to coöperate with other agencies in the community or state which can assist her in furthering her work.

Pearl McIver, director of the Missouri State Department of Public Health Nursing, while at Teachers' College, Columbia University, New York, N. Y., last year, made a study of staff education for rural public health nurses in twelve selected states. She gives six methods of attacking the staff education problems which were used by the directors in these twelve states. These methods can well apply to all types of public health nursing services; so they are enumerated here with an explanation of the way in which each one is used to solve our staff education problems in Indiana.

PERSONAL CONTACTS AT THE STATE OFFICE AND IN THE FIELD

We always encourage new nurses to visit the state office either before taking positions or shortly after, and we explain the resources of the state in health work. They are given an opportunity to talk with the heads of departments of the State Board of Health and our health commissioner himself.

The new nurse visits the university hospitals, with which she has many contacts in the course of her work. She meets the executive secretary of the state tuberculosis association or the Red Cross nursing field representative. We aim to leave nothing undone which will make the nurse appreciate the interest we and the other state agencies feel in her and her work.

Regarding personal contacts in the field, our hope has been to visit each public health nursing service at least twice a year, but with so many services and some of them needing more assistance than others, it has never been possible to get around to them all even once in any year. We try to visit the new nurses early, spending from three days to a week with them.

Since Indiana has so many joint public health nursing services and the American Red Cross has a nursing field representative in the state who sends us reports of her visits to every service and confers with us about them, we agree to have her make the field visits on all services in which the Red Cross participates, leaving us freer to spend more time in the other services.

Tuberculosis association funds are used in more of the county services even than Red Cross funds, and since the state tuberculosis association employs no advisory nurse, our department serves them in that capacity. We consult with the state tuberculosis association executive when we visit any service where tuberculosis association funds are used, and report any developments of interest to his department. Since our department is the connecting link in state

supervision of public health nursing between the Red Cross and the state tuberculosis association, we also report to him anything of interest concerning a tuberculosis service given on the report of the Red Cross nursing field representative, and report to the Red Cross Headquarters in Washington on any service to which the Red Cross is contributing, sending a copy of our letter to the state Red Cross nursing field representative.

Concerning contacts in the field, we sometimes find that spending an evening with a nurse does much more toward creating confidence and good feeling than does contact during hours on duty.

CONTACT BY CORRESPONDENCE AND BULLETINS

The second method of attacking the problems of staff education is by contact with the nurses in the field through correspondence and bulletins.

We believe thoroughly in publicity in public health nursing through our special bulletin, *Echoes*, and through the State Board of Health *Bulletin* to which we contribute. In our State Board of Health *Bulletin* we announce new placements made by our department with a description of the nurses' training and experience, and also mention the nurses who are taking special courses in public health nursing. We believe that these bulletins are giving all the public health nurses in the state a greater group feeling.

REGIONAL CONFERENCES

We have only made a small start, but the experiments so far lead us to believe that the regional conferences can be the very best means of teaching the nurses better ways of doing things, because requests for these meetings come from the nurses themselves.

We have divided the state into five public health nursing districts, the size determined not only by the number of public health nurses in them but by the types of services which they contain. We believe the city staff nurses and the county and town nurses need to get together.

There will probably be a fundamental program arranged for each district, based on the general need of all the nurses and including demonstrations of nursing procedures, but there will be a certain latitude for choice of topics by the nurses themselves which they indicate in the questionnaires sent to them.

ENCOURAGING ATTENDANCE AT STATE AND NATIONAL MEETINGS

We attend the annual meeting of the state tuberculosis association and the Indiana State Conference on Social Work and urge the nurses to attend them, not only for the parts of the program which touch

directly upon nursing, but for the larger vision obtainable of organization possibilities and individual and family case work.

At the annual meeting of our State Nurses' Association a day is given over to a public health nursing program. Our department is always consulted about the program and we coöperate by obtaining speakers and planning special round tables and exhibits for the nurses.

Each year more nurses attend the annual conference of our state health officers. We suggest to our State Health Commissioner for inclusion in the program the names of one or two nurses who are doing outstanding work. The health officers need this contact with the nurses and the nurses need the health officers' point of view.

A loan library which contains the standard and latest health publications is another factor that can be used in promoting staff education in a state. A small one has been started in our state library, and the nurses can either obtain the books from the state directly or through their local libraries.

POSTGRADUATE STUDY FOR NURSES

This can be done in five different ways:

1. By providing scholarships. Since the Indiana State Board of Health does not contribute to the salary of any public health nurse, as some state departments do, we have no funds for scholarships. We always explain to would-be public health nurses the American Red Cross public health nursing scholarships.

2. By maintaining a rural teaching center. This method has never been attempted in Indiana because the state is so situated that the nurses desiring to do county work can easily take public health nursing courses at nearby colleges or get experience on public health nursing staffs in Indiana cities.

3. By offering extension courses. Our department could do a great deal toward presenting the opportunity for extension work to the nurses, and we mean to be more active in this than we have been.

4. By arranging short intensive courses in various specialties. The National Tuberculosis Association and the American Red Cross have held institutes in the state, and we have attended and encouraged the nurses to attend.

5. By arranging for leaves of absence. Many times our department has been instrumental in having a health officer, a superintendent of schools, or a health committee see the advantage of allowing a nurse a leave of absence to visit some good public health nursing service for a week or more for observation; or taking a summer course, or even a year's course, in public health nursing.

The first requisite for developing an effective staff education program is coöperation with other state and national health agencies. We state directors are always preaching coöperation to the nurses out in the field, and I wonder whether we ourselves are coöperating to the fullest extent with other health agencies. A director should not think she is the only authority on public health nursing in her state. Many of our state public health nursing departments would not be in

existence if they had not originally been fostered and financed by two of the unofficial health agencies, the American Red Cross and the state tuberculosis associations. These two organizations, because they are national in scope, are kept from becoming too provincial. They are both doing valuable health work in Indiana and without them and the stimulus they give to lay groups and to us, public health nursing in many communities would be far behind or not even started.

Since so many public health nursing services are financed by combinations of the Red Cross, the county tuberculosis association, the health departments, and school boards, there would be a tremendous amount of confusion among nurses if our department and the state executives for both the American Red Cross and the tuberculosis association did not agree on every point.

I think placement is the most difficult of a state director's work. We never recommend a nurse to a service to which tuberculosis funds contribute unless her credentials have been discussed with the executive secretary of our state tuberculosis association, and no nurse is recommended for a service to which the Red Cross contributes unless her credentials have been submitted to the assistant director of public health nursing for the American Red Cross in Washington. Each organization extends the same courtesy to our department whether or not official funds are being used to finance the service.

The State Nurses' Association can be a bulwark of comfort and assistance to a director who is professional and tries to have the public health nurses live up to the standards set by the state and national nursing associations.

We make every effort to coöperate with the state medical association as an organization and with individual physicians. The publicity bureau of our state medical association sends us 100 copies of its weekly news bulletin release which we send out with our correspondence. Many of the nurses use this material for publicity in their local papers. One of our hobbies is urging better standards of ethics with the medical profession to the nurses at all times.

Effort is made also to have every public health nurse join the National Organization for Public Health Nursing, and subscribe to the *Public Health Nurse*.

Public health and public health nursing are new; state divisions of public health nursing are newest of all, and much still has to be done before their work fully meets all needs. I cannot think of any greater opportunity to serve or of any work which demands greater energy and ingenuity than that which falls to the lot of state directors of public health nursing.

DISCUSSION

PEARL McIVER

*Director Public Health Nursing, Division of Child Hygiene,
Missouri State Board of Health, Jefferson City, Mo.*

IN the study which I made of rural staff education last winter, I found that the number of rural nurses per supervisor varied all the way from 10 to 145 in some states. The average is about 30, and when one considers the time involved in getting from one nurse to another, the difficulties of a state supervising nurse are quite evident. The average number of visits to each nurse is twice a year, and the duration of the visit is about two days.

One of the most valuable phases of our staff education work in Missouri has been our combined conferences of health officers and public health nurses. Seven years ago the nurses met for an annual conference and the health officers held their conference at a different place and time. Two years later we sent questionnaires to all health workers suggesting a combined conference, and by far the majority voted for the combined meeting with joint sessions in the morning and sectional meetings in the afternoon. Last year, many health officers asked that all of the sessions be joint sessions because the nurses had many speakers whom the health officers wanted to hear, and the nurses felt the same way about the health officers' section. Thus next year we will perhaps have very few sectional meetings and more joint sessions.

From these conferences we have developed an affiliated society of the American Public Health Association, and the attendance of rural health workers at the annual meeting is almost 100 per cent.

For several years we have been conducting regional conferences for the nurses, and the non-official health agencies, such as the state tuberculosis association and the Red Cross, have been a big help to me in making these meetings successful. The nurses are asked to suggest topics for discussion, and a tentative program is sent to each nurse for her approval, some time before the conference meets. Since the Missouri Public Health Association meeting is held in the spring and the State Nurses Association in the fall, we plan but two regional conferences in each district during the year, one in the summer and one in the winter. The health officers have not had regional conferences until this year. The health officers suggested that the nurses be invited to have their regional conferences at the same place and time as they. Hereafter we shall plan our meetings together.

Like most states, we have found it difficult to supply the demand for well qualified nurses. We have tried to adhere to the State Board of Health regulations, which require a minimum of 4 months' postgraduate work in public health nursing, or in lieu of the postgraduate training, 8 months public health experience under adequate nurse supervision. In a few instances, we have been forced to accept nurses who do not fully meet these requirements.

For this reason we felt the need for a teaching center where prospective public health nurses can be given a rather thorough introduction to the rural field. We have just established such a center in connection with the Boone County Health Department, and we hope that it may solve some of our problems.

Boone County is a rather typical county with a population of 30,000, 11,000

of whom live in Columbia, the county seat. The rural section is divided into two districts, and there is a nurse in each district. There is an additional nurse in Columbia, with a whole-time medical director, a supervising nurse and an office clerk. The funds for the support of this unit come from the county court, the city schools, Red Cross, tuberculosis association, local welfare society, the State Board of Health, the U. S. Children's Bureau, and the International Health Board; so it is truly a coöperative undertaking.

It is our plan to send every nurse who has not had field experience in rural work to the teaching center for a period of observation and practice. The length of this training period will depend upon the previous experience and training of the nurse; but as a general rule we are planning to keep each nurse at the teaching center for 2 months. Those who have had previous public health experience on a city staff, or an approved theoretical course will be placed in counties by themselves, and those who have not had the required 8 months' experience under supervision will be placed in counties where we have a supervising nurse.

At the present time we have two trainees, and we have planned a series of lectures to be given by representatives of the official and non-official agencies in the state, so that the students will know what agencies exist and what may be expected of each. These lectures will be attended by the entire staff of the unit, and also by the nurses employed in the local county hospital.

Following the 2 months at the training center the nurses will spend a few days at the State Health Department executive offices, familiarizing themselves with the various services and visiting the other departments dealing with education and welfare work. They will also have an opportunity to visit the U. S. Public Health Service Trachoma Hospital at Rolla, Mo., the Deaf School, one of the insane hospitals, and the School for Feeble-minded. Eventually, we hope that either Washington University, in St. Louis, or the State University, in Boone County, will include an approved public health course in its curriculum; then we hope to get our students through the university, and our training center will be used as a practice field for rural nursing by the university.

German Health Centers and Health Museums

HEALTH centers, where advice and information are given free to people of all ages, have been established by local authorities and private agencies in practically all the cities of Germany. In Berlin and several other cities, health museums have also been established, containing collections of exhibits intended to teach the principles of hygienic living. The best known of these is the Museum of Hygiene, in Dresden. This museum maintains traveling health exhibits, which have been shown in about 400 cities in Germany and in several other countries. The work of the museum has gained the recognition of the federal and state authorities, and these are now providing financial aid for its activities; previously it was supported mainly by private funds.—*Vorwärts*, Berlin, July 29, 1928.

MEASLES

THE etiology of measles and its control still remain among the major problems, the first being for the laboratory to clear up, the second for the health officer. The disease is almost universal in its prevalence, and few individuals escape it. It is one of the greatest perils of early childhood, death occurring especially between the ages of 6 and 36 months. The general cause of death is some type of pneumonia, the exact cause of which is not certainly known. While it is generally believed that the pneumonia is induced by a secondary infection, it has been suggested that the microörganism of measles itself is responsible. There are a number of reasons which strongly suggest the latter.

There are conflicting claims as to the germ responsible for the causation of measles, and the most that can be said at present is that the question is undecided. Animal sera have been produced by immunization against several of the germs isolated by different workers. In this country quite glowing reports have been given by certain observers of the protection afforded by the serum of goats immunized against Tunnichliff's organism. Hoyne and Gasul¹ reported 88 per cent protection of 44 exposed non-immunes, the remaining 12 per cent having had only a mild attack. Halpern² claims to have produced protection in 63 per cent of 45 patients exposed. Of the remainder, 17 developed the disease in a mild form, which the author speaks of as an "attenuated form," for just what reason it is not clear, since so many children have a mild type of the disease under any circumstances.

A recent critical study of four immune sera has been made in England:³ (1) Tunnichliff's horse serum, (2) Ferry and Fisher's horse serum, (3) Degkwitz's sheep serum, and (4) Serum from convalescent

cases of measles. While the animal sera, with the exception of Ferry and Fisher's, gave some protection, all were found deficient, and all gave a certain number of serum reactions, running as high as 33.3 per cent for one. On the other hand, human convalescent serum gave no reactions, and apparently protected in 95.7 per cent of the cases in which it was used. Approximately 22 per cent of the control cases escaped infection, showing that the negative history was either inaccurate or that the patients were naturally immune, so this finding must be taken into consideration in judging of the protection apparently afforded by the sera.

Our conclusions, derived from a rather extensive review of the literature, accord with those reached by Gunn as the result of the experiments just recorded,—namely that all animal sera so far produced are uncertain and deficient in protective power, and that human convalescent serum is the only reasonably sure prophylactic known. Its use has been shown to be safe, free from unpleasant reactions, and dependable. The great drawback to its extensive employment lies in the difficulty of obtaining it in sufficient quantities. We must still hope for the production of an animal serum which will be free from this drawback.

BREAD AND YEAST

THE amazing success of the campaign by certain manufacturers to encourage the eating of yeast gives interest to any information concerning this remarkable plant. Additional interest comes from the tendency evident in many parts of the world to "purify" wheat flour. This purification consists in the complete removal of the hull and the germ, those parts of the grain which carry the vitamins, protein and mineral salts. In general, the same statement may be made concerning another staple food, rice, the study of which began, and has added greatly to, our knowledge of vitamins.

In this country, eating of yeast holds the public attention to a remarkable degree, but there is little discussion over the excessive milling and refinement of flours, except among specialists. In England the question of white bread as against wholemeal bread has been more or less active for a number of years, and is especially so at present, owing to the formation of a society, some of the members of which regard the use of white bread as a crime, and the wide publication of articles by certain prominent men.

In that country, wholemeal bread is somewhat more expensive than white bread, and since bread makes up about two-fifths of the food-stuff of the population, many of whom are extremely poor, the importance of the matter from a national standpoint is evident.

Some have taken comfort in the supposed protection afforded by the use of yeast to raise bread. It has, however, been shown that the amount of yeast added, as well as that present at the time of baking, averages slightly above 1 per cent, which is not enough to make up for the loss due to high milling; indeed, it is only about one-tenth of what is required to give a sufficiency of vitamin B. It has been definitely shown that vitamin B contains at least two factors, both of which are necessary for health and growth, and recent experiments¹ have shown that the addition of 2 to 4 per cent of dried yeast will produce a bread equal nutritively to the best wholemeal product. Such a bread is palatable and cheap. Vienna bread, which is imitated in many parts of the world, and is noted for its palatability, contains an unusually large amount of yeast. The addition of yeast requires no new machinery such as would be required for a decided change in the milling processes. It seems probable that brewer's yeast is better fitted for this purpose than other yeasts; and it must be dried at a sufficiently high temperature to destroy the diastatic enzymes, in order to avoid undue fermentation which an excess of yeast might bring about. Any yeast which is to be utilized should be examined, and tested for its vitamin B content. As far as experiments show, its use, even in large quantities, is free from danger, and the proteins which it contains are utilizable in from 30 to 50 per cent of the total diet.

The entire question is one of increasing importance, owing to the growing practice of bleaching flours which are highly milled to begin with, the substances used in bleaching tending to destroy what vitamins may be left.

THE PATIENT AMERICAN!

A NEW view on the American comes from an English medical journal¹ in a review of the brochure on scarlet fever issued by the U. S. Public Health Service. The criticism is made that it is much too long (5,000 words), at least for British consumption. The British are said to become bored after reading two thousand words, and anything beyond this usually leads to impatience and exhaustion, so that the article is likely to be cast aside. The opinion is ventured that the

Americans, contrary to what is usually believed of them, read and listen better and for longer periods than the English.

We wonder how much truth there is in this conjecture. We believe that it is fallacious. Among the outstanding characteristics of Americans is an enormous energy in doing things—which may extend to learning how to do them—but an impatience with presentations which are too long and deal too much with details, unless these details are necessary for the accomplishment of work.

Very recently, we have read a criticism of a book² in which its length and size, and the consequent fatigue of holding it during perusal, are emphasized. We note in a number of reviews that the weight of paper upon which a book is printed is mentioned, and the light-weight paper of the English publishers commended. Our observations also lead us to believe that the average American reader does what women are accused of doing with novels—reading the last page first. For scientific articles this means reading the conclusions. If the reader is particularly interested in the subject and needs further information, the article may be studied. Further, practically all medical and public health journals have cut down on bibliography and history. There are several reasons for this, such as the expense of printing, and a pretense of study often not justified; but we believe that the great reason lies in the desire of readers for a concise presentation of facts.

There is no question that an enormous amount of work is being done in this country, and just as little question that the individual workers will dig into literature with almost inexhaustible patience when necessary. On the other hand, we are compelled to believe that the average American is not so familiar with literature, so widely read, nor so patient in acquiring knowledge as the average Englishman or European. Vaughan,³ in advocating the historical method of teaching, points out that when meningitis appeared in America, we lost many precious months in learning facts which had been “demonstrated conclusively by French army surgeons in the first half of the 19th century.”

While we appreciate the compliment to our American people, we fear that we cannot accept it without reservation.

ASSOCIATION NEWS

COMMITTEE ON COÖPERATION, DEVELOPMENT AND FINANCE

At the Governing Council meetings in Chicago a new Committee on Co-operation and Development was authorized, this committee being charged with the study of fundamental Association problems, including those relating to affiliated societies, and to work out suitable coöperating relationships with other national and local agencies that are active in the field.

A motion of the Finance Committee which was approved by the Council, recommended the enlargement of the Finance Committee with a view to studying the financial structure of the Association and developing a financial policy adequate to carry out the Association's growing program.

An amendment to the By-laws provides that the chairman of the committee shall be a member of the Executive Board.

These two committees have been joined in the new Committee on Co-operation, Development and Finance, which held its first meeting in the offices of the Association on November 10. The committee first addressed itself to the task of formulating a simple statement of the principal aims and objectives of the Association. It has requested several sub-committees and standing committees of the Association to elaborate on several parts of this statement.

The present personnel of the committee is: Louis I. Harris, M.D., Chairman, W. S. Rankin, M.D., C. F. Wilinski, M.D., Sally Lucas Jean, Abel Wolman and Arthur Gorman, together with the President, Treasurer and Secretary who are members ex officio.

The next meeting of the committee

will be held on December 7, following which they will have a joint dinner with the Executive Board which meets on December 8.

MINNEAPOLIS LOCAL COMMITTEE

The President has appointed William F. Kunze as Chairman of the Local Committee for the 58th Annual Meeting to be held in Minneapolis, Minn., during the week of September 30, 1928. Mr. Kunze is director of the Minneapolis Department of Public Welfare and is President of the Hennepin County Public Health Association.

OHIO SANITARIANS MEET

There were 305 registered and affiliated members attending the Ninth Annual Meeting of the Conference of Ohio State Health Officers and the Ohio Society of Sanitarians held November 7-10 at Columbus, O., and of this number 200 were health officers and public health nurses.

The following officers were elected: President, C. D. Barrett, M.D., Loraine County; First Vice-president, Edgar R. Hiatt, M.D., Health Commissioner of Miami County; Second Vice-president, Marion Howell, R.N., Western Reserve University; Secretary-treasurer, E. R. Schaffer, M.D., Ohio State Department of Health; James A. Beer, M.D., F. Holman Waring, and Mrs. Zoe McCaleb, members Executive Committee.

Harry L. Rockwood, M.D., Health Officer of Cleveland, was elected as representative on the Governing Council of the A. P. H. A.

W. F. Walker, D.P.H., field director for the Committee on Administrative Practice, represented the American Public Health Association.

This meeting was considered the best that the Ohio health officers have had and among the outstanding contributions were the papers read by Frank G. Boudreau, M.D., representing the Health Division of the League of Nations, Geneva, Switzerland, who was also elected an honorary member of the Ohio society; Walter Simpson, M.D., of Miami Valley Hospital, Dayton, O., on "Tularemia"; and Edward Francis, M.D., on "Tularemia and Undulant Fever"; and by Dr. Rockwood on "Control of Tuberculosis."

While in Ohio, Dr. Walker took the opportunity to discuss with Dr. Monger, Ohio State Health Officer, the survey of health activities of the Ohio State Department of Health, recently made by James Wallace, M.D., associate to Dr. Walker.

DEATH OF MRS. SEDGWICK

Mrs. Mary Sedgwick, the widow of the late Dr. William T. Sedgwick, a former President of the Association, died Tuesday morning, November 6, in New York, N. Y. Mrs. Sedgwick had been confined to her bed for over a year, due to an injury received in a fall. Funeral services which were held at the St. Luke's Hospital Chapel, New York, N. Y., were attended by several of Professor Sedgwick's former students at Massachusetts Institute of Technology and representatives of the Association.

NEW OFFICERS FOR DELTA OMEGA

Lieutenant Colonel Edward G. Huber, of the U. S. Army Medical Corps, was elected president of the honorary public health society, Delta Omega, at its fifth annual meeting, held at Chicago, October 15, 1928, during the convention of the American Public Health Association. C. C. Young, D.P.H., Michigan State Department of Health, was elected vice-president, and James A. Tobey, LL.B., Dr.P.H., New York, was re-elected secretary-treasurer. The Delta Omega Society now has about 200 mem-

bers belonging to six chapters located at the Johns Hopkins School of Hygiene and Public Health, the Harvard University School of Public Health, the Massachusetts Institute of Technology, the University of Michigan, the Yale School of Medicine, and the University of California.

MR. FULLER CALLS ON DR. HARRIS

Before leaving Chicago, where he was elected President of the American Public Health Association, George W. Fuller called on Malcolm L. Harris, M.D., the president-elect of the American Medical Association. Mr. Fuller paid his official respects to Dr. Harris and assured him of his desire to coöperate with him to bring about a better understanding between public health workers and the medical profession.

DEATH OF FRED BERRY

Fred Berry, 44 years of age, Chief of the Division of Laboratories, Ohio State Department of Health, Fellow of the American Public Health Association, and a frequent contributor to the AMERICAN JOURNAL OF PUBLIC HEALTH AND THE NATION'S HEALTH, died at his home in Columbus, October 20, after several months' illness from Bright's disease.

Mr. Berry was graduated from the Ohio State University in 1906 and immediately became affiliated with the Department of Laboratories of the Ohio State Department of Health. He held a Master's Degree from the Ohio State University and at the time of his death he was completing his thesis for his Ph.D. degree from the University of Chicago.

In 1918 he resigned from the department, to join Dr. J. McI. Phillips in the operation of the Columbus Pasteur Institute, and a year later he returned to the State Department of Health to become chief of the division of laboratories.

NEW MEMBERS

- Fred L. Adair, M.D., Minneapolis, Minn. (Assoc.)
- Magnus W. Alexander, New York, N. Y. (Assoc.)
- Henry A. Allen, Chicago, Ill., Mechanical Engineer in charge of Department Public Works, Bureau of Engineering
- John S. Bengston, Ph.G., D.V.M., Washington, D. C., Bacteriologist and Pathologist, Bureau of Animal Industry, U. S. Department of Agriculture
- Clifford E. Blackburn, Toronto, Ont., Member Toronto Health Board
- Ruth Alice Boak, M.S., Albany, N. Y., Assistant in Research, Department of Pathology, Albany Medical School
- Emily F. Bolcom, M.D., Boise, Ida., Director Bureau of Child Hygiene, Department of Public Welfare
- Faye C. Bowen, Jackson, Mich., County Nurse
- Herbert E. Bowman, Ph.G., Somerville, Mass., Milk Inspector and Milk Bacteriologist
- J. L. Bowman, M.D., Montgomery, Ala., County Health Officer
- Alfred David Browne, M.D., Nashville, Tenn., Professor of Health Education, Peabody College
- Francis H. Bulot, Chicago, Ill., Consulting Sanitary Engineer
- Clare W. Butler, Albany, N. Y., Temporary Research Statistician, State Department of Health
- John Deere Cady, Chicago, Ill. (Assoc.)
- Douglas Launeese Cannon, M.D., C.P.H., Montgomery, Ala., Acting State Health Officer
- Lillian S. Carlson, Chicago, Ill., Tuberculosis Field Nurse, Washington Blvd. Dispensary
- Philip R. Carter, Minneapolis, Minn., Milk Sanitation, Division of Sanitation, State Department of Health

LETTER TO THE EDITOR

TO THE EDITOR:

There seems to exist a considerable misunderstanding as to the auspices under which the various health demonstrations in the United States have been conducted. This misunderstanding appears to prevail not only among the general public, but to some extent among the medical profession and through the public health field. Statements have recently been published to the effect that the health demonstration in Mansfield, O., completed two or three years ago, was financed and directed by the Commonwealth Fund. At the recent meeting of the American Public Health Association in Chicago, the inaccurate statement was made by one of the speakers that the demonstrations of the Commonwealth Fund are operated by the American Child Health Association. It therefore seems worth while in the interest of clarity to make the following statement:

The Child Health Demonstration Committee of the Commonwealth Fund has financed and conducted a health

demonstration in Fargo, N. D. This demonstration was completed December 31, 1927. The same committee of the Fund has also conducted demonstrations in Clarke County, Ga.; in Rutherford County, Tenn.; and in Marion County, Ore. The first two of these will be completed December 31, 1928. The Marion County Demonstration will continue until the conclusion of the 5-year period as agreed upon. The Commonwealth Fund is responsible, and exclusively responsible, for the policies adopted in the operation of the above named demonstrations. It is not responsible for any other health demonstration whatsoever, and has never had any connection, financial or other, with any other health demonstration.

I shall appreciate it if you will publish this statement in your valuable journal.

Barry C. Smith,
 Director

The Commonwealth Fund,
 New York, N. Y.,
 October 20, 1928

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Wholesale Life Saving—The practicing physician is compared to the retailer and the public health officer to the wholesaler in the promotion of the public health. The physician considers the individual as a unit while the public health worker must think in terms of the community as a whole. The physician writes the individual prescription for the patient while the health officer must lay out a broad and far-reaching program. The physician has been trained in the school of defense, to attack disease as it appears. The health officer has been trained in the school of attack, the application of preventive measures.

Public health work has increased rather than decreased the practice of competent physicians; to function properly health organizations must have the coöperation of organized medicine; aside from the control of communicable disease, the care of the indigent sick is not a public health problem; special training is essential for the public health worker; preventive medicine should be emphasized in teaching in medical schools; every physician's office should be a health center; health departments and unofficial health organizations should not practice curative medicine.—Homer N. Calver, *Retail or Wholesale Life Saving: Which Pays the Better?*, *J. A. M. A.*, 91: 1285 (Oct. 27), 1928.

Measles Antitoxin—During an outbreak of measles in Detroit, Mich., antitoxin prepared from a green-producing streptococcus isolated by Ferry & Fisher was used to protect contacts against measles in certain institutions.

At the Children's Hospital, where the treated patients were controlled with an equal number of untreated patients under the same conditions, the computed actual protection, following the use of 20 c.c. measles streptococcus antitoxin, was 88 per cent. At the Herman Kiefer Hospital 10 c.c. of antitoxin was used and controlled with a much larger number of untreated cases and also controlled with a group which received 5 c.c. measles convalescent serum. The computed protection with antitoxin was 42 per cent compared with 19 per cent for those treated with measles convalescent serum.—N. S. Ferry, *et al.*, *Clinical Results with Measles Streptococcus Toxin and Antitoxin*, *J. A. M. A.*, 91: 1277 (Oct. 27), 1928.

Small Town Survey—A sanitary and health survey was made of 18 incorporated towns and 1 small city all located in Darke County, O. Each house in the county was visited and inspected between June, 1927, and February, 1928. Residents were interviewed with regard to family history and tabulations were made of sanitary conditions found. The federal census for 1920 gave 16,167 as the population. The population actually found or estimated by the surveys was 14,111, showing a loss of 12.7 per cent. In this population there resided 931 individuals who gave a history of having suffered from typhoid fever at some period of their lives. This represents 7.9 per cent of the population. Four hundred and fifty-three individuals have had smallpox. It was found that 60 per cent were unprotected by previous attack of

the disease or by recent or remote vaccination. Approximately 80 per cent of the children of school age were unprotected.

Among the outstanding health problems demanding the attention of the various authorities are the safeguarding of the milk supply, the elimination of typhoid carriers from food handling establishments, adequate protection of the water supply, safe disposal of sewage, immunization against smallpox and diphtheria, location and care of tuberculosis cases and health education.—M. E. Barnes, *The Health Problems of the Small Town as Determined by the Survey Method*, *Ohio State M. J.*, Sept., 1928.

Diphtheria Prevention Campaigns
—During the past several years local communities throughout the country have been carrying on intensive campaigns to secure the immunization of young children against diphtheria. During such campaigns the health department has established many free clinics, at which toxin-antitoxin could be secured. These have included the regular health department clinics, infant welfare stations, school clinics and other special clinics. In Syracuse and Detroit campaigns are now being inaugurated in which there will be no free clinics but the health department will devote all of its energy toward securing immunization at the hands of the family physician. The outcome of such a pro-

gram will be watched with keen interest. Success depends upon the united support of organized medicine. In each instance the health department will, of course, continue its policy of education through the many channels which have been used for this purpose and will also serve as a depository for records. (Those who are carrying on campaigns this year involving unique features are urged to submit their experiences to the Editor of this section of the JOURNAL.)

Bellevue-Yorkville Demonstration
—In October, 1928, the Bellevue-Yorkville Health Demonstration in the City of New York issued a reference handbook on the principal causes of mortality during the pre-demonstration. The handbook, which consists of tables and charts, was prepared by G. J. Drolet, Consulting Statistician. There are portrayed the vital statistics for the 5 years, 1922–1926, with separate information for 1925 and 1926, intended as a handbook in guiding projects and in measuring the progress of the work which has been undertaken. Separate data have been published for each of the 25 sanitary areas, and the general death rate of each area has been standardized to enable comparisons with other areas and with the United States as a whole. The general death rate during the 5-year period averaged 17.35; standardized, 16.99. Leading causes of death were organic heart disease, pneumonia, accidents, tuberculosis and cancer.

LABORATORY

C. C. YOUNG

COMPARATIVE STUDIES IN THE LABORATORY DIAGNOSIS OF SYPHILIS

MARCELLA OGLESBY AND HAROLD J. KNAPP, M. D., FELLOW A. P. H. A.

Laboratories of the Division of Health, Cleveland, O.

THREE thousand sera were tested by the Wassermann, Kahn and microscopic slide precipitation tests, in an effort to devise a reliable and practicable system for the diagnosis of syphilis in this laboratory. It was thought that this series would aid in the evaluation of the relative merits of the three tests.

The Wassermann test was performed according to the Cleveland Method,¹ with a cholesterolized antigen of exceptional sensitivity.

The Kahn test was performed as described by Kahn² in his book, *Serum Diagnosis of Syphilis by Precipitation*, with a standard antigen kindly supplied by him. Later a standard Kahn antigen prepared by us, but titrated also in Dr. Kahn's laboratory, was used.

The microscopic slide precipitation test was performed, as described by Kline and Young,³ except that mixing was done by rotation alone, the use of a toothpick having been found unnecessary by the authors of the test, since the publication referred to. The antigen was furnished by Dr. Kline, and was prepared by him as described in a re-

cent article.⁴ The "very sensitive emulsion" was used in this series.

The results of the comparative tests are recorded in the following tables. (In cases of disagreement, whenever there was sufficient sera, tests were repeated.)

The agreement between the three tests was, on the whole, very close. Greater positivity was shown by the Wassermann and slide tests, in both of which the most sensitive antigens were used, than by the standard Kahn test. It is reasonable to assume that greater agreement would have been reached if the special, more sensitive Kahn antigen had been used, as in his presumptive test.⁵ The high positivity of the Wassermann in this series is believed to be due in part to the unusual sensitivity of the Wassermann antigen used. This antigen was so sensitive that routine replacements of it would be unlikely. It is probable that in a routine procedure where antigens of ordinary sensitivity are used, relatively more positive results would be obtained by both Kahn and slide tests.

TABLE I

	TOTAL No.	POSITIVE	DOUBTFUL	NEGATIVE	A. C.
KAHN	3,000	548 = 18.26%	52 = 1.73%	2,400	
WASSERMANN	3,000	643 = 21.43%	19 = 0.63%	2,338	33
SLIDE	3,000	662 = 22.06%	53 = 1.76%	2,285	

++, +++ and ++++ are considered positive; + and ±, doubtful.

TABLE II

TOTAL No.	COMPARISON OF WASSERMANN AND KAHN TESTS	
3,000	99 positive Wassermann reactions gave negative Kahn reactions	Agreement 93.2%
	34 negative Wassermann reactions gave positive Kahn reactions	
	53 Wassermann reactions gave weaker Kahn reactions	Agreement and
	14 Wassermann reactions gave stronger Kahn reactions	Rel. Agr., 95.5%
COMPARISON OF WASSERMANN AND SLIDE TESTS		
3,000	66 positive Wassermann reactions gave negative Slide reactions	Agreement 93.4%
	63 negative Wassermann reactions gave positive Slide reactions	
	29 Wassermann reactions gave weaker Slide reactions	Agreement and
	38 Wassermann reactions gave stronger Slide reactions	Rel. Agr., 95.6%
COMPARISON OF SLIDE AND KAHN TESTS		
3,000	106 positive Slide reactions gave negative Kahn reactions	Agreement 92.7%
	17 negative Slide reactions gave positive Kahn reactions	
	83 Slide reactions gave weaker Kahn reactions	Agreement and
	12 Slide reactions gave stronger Kahn reactions	Rel. Agr., 95.9%
ANTICOMPLEMENTARY REACTIONS		
33	17 A. C. reactions gave positive Kahn reactions	
	21 A. C. reactions gave positive Slide reactions	

Positives with positives, doubtfuls with doubtfuls, negatives with negatives, are considered agreements; positives with doubtfuls are considered relative agreements; only positives with negatives are considered disagreements.

To determine the merits of the microscopic slide method as compared with the tube method, the following tests were performed on 1,000 sera: one, the regular slide test with Kline antigen; the other, a tube test exactly like the Kahn, except that the same Kline antigen was employed as was used in the slide test. There were no disagreements. There were sixteen relative agreements in which the slide test gave more strongly positive results, and one in which the tube test showed stronger positivity.

This would seem to indicate that clumping on the slide is somewhat better than in the tube. Microscopic readings in the slide test are striking, and are much easier to read than are macroscopic readings in a tube.

A comparison of the standard Kahn antigen with the Kline "very sensitive antigen emulsion" was made by performing two tests on each of 1,000 sera: one, the standard Kahn test; the other, a test similar in every respect, but utilizing the Kline antigen.

The results of this comparison are given in Table III:

A comparison of the Kahn Presumptive Test with the slide test using Kline V. S. A. E. would be interesting, and is in prospect.

CONCLUSIONS

Innumerable Kahn tests performed in various laboratories have established the reliability of precipitation procedures in the diagnosis of syphilis. It has been decided to discontinue the Wassermann

TABLE III

TOTAL No.	COMPARISON OF RESULTS WITH TWO ANTIGENS	
1,000	51 tests positive with Kline V. S. A. E. were negative with standard Kahn	
	4 tests positive with standard Kahn were negative with Kline V. S. A. E.	
	20 tests gave stronger reactions with Kline V. S. A. E.	
	7 tests gave stronger reactions with standard Kahn	

in the Cleveland Division of Health Laboratories, and replace it with two precipitation tests: the standard Kahn, and the slide with the Kline V. S. A. E. It is believed the two will supplement each other excellently. The standard Kahn is a well-tried test of satisfactory sensitivity. In the slide test, a maximum of sensitivity will be obtained. Local experience thus far indicates that a negative slide test (Kline V. S. A. E.) gives as complete an assurance of freedom from luetic infection as may be given by any one serologic test. It should therefore be of especial value in problems of immigration, food control, or court action.

The presumptive Kahn may give the same assurance, but it has not been tried out in this laboratory. The slide test was chosen rather than the presumptive Kahn because it requires less serum, is easier to read, quicker to perform, and gives uniform results at low temperatures.

The determination of the occurrence or absence of non-specific reactions in the slide test using the V. S. A. E., as in the Kahn presumptive test, should be

left to clinical workers, since clinical data obtained at a public health laboratory are both meager and unreliable. However, data presented in work as yet unpublished by Kline, *et al.*, indicate that the Kline reaction is specific.

In these laboratories, disagreements between the two tests are carefully rechecked. Where serum is positive by the slide test and negative by the Kahn, a Kahn presumptive test is performed, and also a slide test using the sensitive antigen emulsion. Better results are thus obtained than was possible with a single Wassermann; while less time, effort, and expense are required, due to simplicity of procedure in precipitation tests.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Deaths of Wage Earners—Figures based on conditions existing among wage earners insured in the Metropolitan Life Insurance Company, show that wage earners who die between the ages of 35 and 45 years leave on the average 2.7 young children. Those dying between 25 and 35 years leave on the average 2.1 dependent children, while those under 25 leave 1.4 such dependents. Of all the fathers, aged 35–44, who died with dependent issue, more than 70 per cent left 2 or more children under 16. Nearly one-fifth of such fathers left 4 children, and nearly one-fifth, 5 or more children. Among the fathers dying between 25 and 35, approximately 60 per cent left 2 or more dependent children; while of deceased fathers below 25, about one-third left 2 or more dependent children. Foreign born fathers leave more dependents, on the average, than do the native born, but the number left by colored men does not differ essentially from that by whites.

A relatively few causes of death are responsible for the major part of this family damage. In the interval 25–44 years, nearly 6 deaths out of every 10 among white male wage earners were due to tuberculosis, influenza, pneumonia, heart disease and accidents. These conditions cause, respectively, 22.7 per cent; 12.6 per cent; 11.5 per cent and 14.2 per cent of the total mortality.—*Stat. Bull.*, Met. Life Ins. Co., 9: 7–9 (Sept.), 1928.

Deaths among Jews—A study was made in 1925 of the mortality records of 557 Jews in the State of New York, outside of New York City. Buffalo

recorded 141 deaths among Jews, Albany 55, Syracuse 41, and Mount Vernon 21. Seventy-six deaths occurred in rural New York, and 35 of these were in Sullivan County where there are a number of tuberculosis sanatoria. It was found that 36.2 per cent of the decedents were native born, and 63.6 per cent foreign born. Forty per cent were Russian by birth; 8.8 per cent Polish; 5.0 per cent German; 4.8 per cent Austrian; 1.7 per cent Hungarian and 0.8 per cent English, Scotch or Welsh.

The proportion of deaths from heart disease was higher among Jews than for the general population of the state, exclusive of New York City, being 23.0 per cent of all deaths for the former and 20.5 for the latter. In the age group 15–24 years the proportion ascribed to heart disease was three and one-half times greater than the corresponding figure for the general population. The deaths due to diseases of the respiratory system were 10.9 per cent of all deaths among Jews and 8.7 per cent among the general population. The excess was particularly marked after the 65th year, being 14.9 per cent for Jews and only 7.1 per cent for the general population. The proportion of deaths from cancer was somewhat lower among Jews, being 8.2 per cent, as contrasted with 9.1 per cent. The deaths from tuberculosis were 7.3 per cent for Jews and 6.6 per cent for the general population. In the younger age groups, however, the proportion among Jews was considerably lower. In the 15–24 year group there were 25.0 per cent deaths among Jews in contrast with 31.6 per cent, and in the 25–44 year group, 18.8 per cent in

contrast with 22.3 per cent among the general population. The proportion of deaths from diabetes among Jews was more than double that for the general population, being 4.2 per cent and 1.7 per cent, respectively. In the age group 45-64 years deaths from diabetes were 9.3 per cent among Jews and represented almost one-tenth of the total deaths. Diseases of the digestive system were responsible among Jews for 6.1 per cent of all deaths.—J. V. De-Porte, *Causes of Death among Jews in New York State (Exclusive of New York City)*, 1925, *New York State J. Med.*, 28: 1155-1159 (Oct. 1), 1928.

Health of London 1927—The population of the County of London in the middle of 1927 was estimated at 4,555,000 including 9,000 non-civilians. The births during the year were 73,263, giving a birth rate of 16.1 per 1,000, which is lower than for 1926 and 1925. Since 1921 the number of births has been decreasing at the rate of 4,000 annually. The deaths were 55,170 or 12.1 per 1,000. This rate is higher than in the two preceding years.

Five cases of smallpox occurred in the county, of which two were fatal. Three patients were unvaccinated at the time of infection, and 2 of these belonged to the fatal group. Up to December 31, 1927, a total of 115 children was dealt with at a special clinic for diphtheria carriers; 56 were able to return to school in less than 4 weeks, 32 in 4 to 8 weeks and 1 was under treatment for 19 weeks. The remainder were still under treatment. Deaths due to diarrhea were considerably below the average. The mortality from puerperal fever was much lower in boroughs with poorer class populations than in those occupied largely by the well-to-do. During the 5 years 1921-1925 the average annual death rate per 1,000 births was 0.88 for a poorer group of boroughs and 1.80 for a well-to-do group. In

1927 there were 267 notifications of puerperal fever and 892 of puerperal pyrexia. The deaths from cancer during 1927 were 6,774 with a death rate of 1.49, which is higher than in 1926 and 1925. The cancer mortality among women has been decreasing in London in the last ten years.—*Brit. M. J.*, 2: 448-449 (Sept. 8), 1928.

Population of Germany—The extremely low birth rate of the war years and the decline of the postwar period, together with the losses in able-bodied men, have materially changed the distribution of the various age groups in Germany. The excess of boys over girls in the first years of life is now even greater than it was before the war. According to the last prewar census there were 505 boys per 1,000 children under 1 year; in 1925 there were 509 per 1,000. The birth losses of the war period affected the census of 1925 almost exclusively in the 6 to 10 age groups. In the 7 and 8 year olds the numbers are not equal to 50 per cent of the prewar status. The 10 to 25 age groups were not markedly influenced by the effects of the war. The losses of men on the battlefields have produced in the age groups a marked excess of women over men. In the 25 to 30 group there was in 1925 an excess of 1,151 women over men as compared with 1,002 in 1910. The 30 to 35 group shows an excess of 1,260 in 1925 as contrasted with 1,001 in 1910. There are more adults and fewer children than before the war. In 1910, 33.9 per cent of the total population of the country was under 15 years of age; according to the census of 1925 only 25.7 per cent was under 15 years. In 1925 the number of children between the ages of 6 and 14 was about one-fourth less than in 1910. The number of minors in Germany is now 38.2 per cent of the total population, as compared with 45.3 per cent in 1910.

Since 1910 the number of unmarried men decreased 4.4 per cent while the number of unmarried women increased 0.2 per cent. The widowers have increased 12.7 per cent and the widows 21.7 per cent. Among women the increase is chiefly in the middle age groups. The number of divorced men has increased 119.2 per cent, and the women 120.6 per cent. This increase is especially noticeable in the younger age groups.—*J. A. M. A.*, 91: 977-978 (Sept. 29), 1928.

Vital Statistics of Germany for 1927—In the vital statistics of Germany for 1927, the increase in the number of marriages is especially significant. In 1926, there were 483,198 marriages contracted; for 1927, the number was 538,525, an increase of 11.5 per cent. This increase from 7.8 per 1,000 population, in 1913, to 8.5 per 1,000 in 1927 is all the more striking in view of the fact that the percentage of married men was already much higher than in the prewar period. The increase was especially marked in the large cities: Berlin, Hamburg, Bremen, and in certain provinces or states: Saxony (18 per cent), Upper Silesia, and Thuringia. The Prussian Bureau of Statistics ascribes the increase to the fact that the proportion of persons of marriageable age to the whole population was much greater than before the war. In 1910, Prussia, with a population of 40,000,000, had 22,300,000 above the age of 20, whereas, in 1925, with a population of 38,000,000, there were 24,200,000 above the age of 20. Unfortunately, in spite of the increase in the number of marriages, there was a decline in the number of births. If we note further that the number of women of childbearing age in the whole population is 2,700,000 greater than before the war, and that, in spite of that fact, the number of living births was decreased by about 445,000, the decrease in the number of

births appears even more significant. In Berlin, the birth rate has fallen from 19.4 (1913) to 10.6 (1927).

The total number of deaths in 1927 was 757,000, or 22,900 more than in 1926. The death rate in 1913 was 14.8; in 1927, 12.0. The increase of the mortality for 1927 over that of 1926 was due chiefly to the influenza epidemic of the first quarter and to the unfavorable weather conditions, especially during the last quarter of 1927. The infant mortality for 1927 shows a further decline. Owing to the drop in the birth rate and to the increase in the death rate, the net gain in population for 1927 was 90,000 less than for 1926. The excess of births over deaths (403,000) is only about half that of the prewar period.—*J. A. M. A.*, 91: 1208 (Oct. 20), 1928.

A Decline in Birth Rates in Japan—In recent years, the extraordinarily high birth rate of Japan has astonished the world. According to the records of the bureau of statistics, the numbers of births for the last half-century were: 1872, 57,000; 1883, 1,000,000; 1915, 1,500,000; 1920, 2,000,000; 1926, 2,100,000. The principal causes of the rapid rise of the birth rate after the Meiji restoration in 1868 were investigated and found to be as follows: (1) The people have married in order to have children; (2) the law has prohibited birth control, which was practiced in the Tokugawa era just before the restoration; (3) their marriages have not been contracted as early as in former times, when boys of 16 or 18 married girls as young as 13; (4) one of their principal foods is fish, which is thought to enforce the reproductive power; (5) venereal and other diseases which affect the nervous system have not been so frequent recently; (6) an income tax allowance has been made for the children, as in England.

The climax of the high birth rate

seems to have come in 1926, as the births in 1927 were 50,000 less than in 1926. At the same time the infant mortality rate has become higher than ever, owing to beriberi, tuberculosis and hereditary venereal disease. As a result, the Tokyo authorities are planning to investigate all births and miscarriages of women up to 40 years of age in the city.—*J. A. M. A.*, 91: 1205-6 (Oct. 20), 1928.

Vital Statistics of Singapore 1927

—The population of Singapore for the year 1927 was 428,153. The total number of deaths for the year was 14,165, and the death rate was 33.08 per 1,000 population compared with 32.04 in 1926 and 28.21 in 1925. The birth rate was the highest on record, being 33.05 per 1,000 in contrast with 31.52 in 1926 and 31.19 in 1925. There was an infant mortality rate of 228 per 1,000, the corresponding figure for 1926 being 232. The infant mortality rates ranged from 146 for Europeans to 219 for Chinese and 355 for Malays. Making corrections for Chinese emigration, the Chinese rate was about 181. Among the notifiable diseases there were 19 cases of smallpox and 7 deaths; 29 cases of diphtheria and 9 deaths; 2 deaths from whooping cough and 8 from measles; there were no scarlet fever cases. Tuberculosis caused 1,523 deaths and pneumonia 2,291, in contrast with 1,370 and 1,843, respectively, for 1926. The deaths from these two diseases constituted 25 per cent of the deaths from all causes. There were 272 deaths from heart dis-

case during the year, and 606 from diarrhea and enteritis. Ninety-one deaths were due to puerperal causes, and 354 to accidents.—*Ann. Rep. Health Dept. Singapore for 1927.*

Decline of Vienna's Birth Rate in 1927—The recent report on the vital statistics of Austria for 1927 contained the following data: The number of marriages for the year was increased over that of the previous year, but in Vienna there was a decline from 17,791 to 16,257. The number of living births in Austria was 8,182 below the registration for 1926. The birth rate dropped from 19.7 per 1,000 to 18.3 per 1,000, whereas in 1913 the birth rate was 24.4. The mortality in 1927 was little different from that of 1926. In some of the provinces, especially in the rural districts, there was a slight decrease in mortality. The regions with the highest birth rates present also the highest mortality. The mortality of Vienna is somewhat lower than the average for Austria. The excess of births over deaths (for Austria as a whole) is falling rapidly. This is due to the decrease in the birth rate and the very slight increase in the death rate. In Vienna in 1927 there were 20,888 living births (in 1926, 22,223; in 1913, 37,632). This represents a decline of 40 per cent from the record for the last year before the war. The decrease in the population of Vienna for 1927 amounted to 5,574, whereas in 1916 the population remained unchanged and, in 1913, had shown an increase of 4,977.—*J. A. M. A.*, 91: 1050 (Oct. 6), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Water Supply Contaminated through Bleeder Valves—Crisfield, Md., a fishing hamlet of approximately 4,000 people, situated in Somerset County on the Little Annemessex River, is supplied with water from drilled wells. It has no sanitary sewerage system and but one storm sewer. The topography is flat, the greatest elevation above mean sea level being between 7 and 8 feet. When analytical results of tap water samples indicated an "abrupt and serious deterioration" of the quality of the water supply, representatives of the Maryland State Department of Health made an investigation. A unique and interesting cause of contamination was revealed.

The first discovery was that an ice plant was returning condenser cooling water to the receiving basin of the city supply. An inspection of the condenser basin disclosed that it contained approximately an inch of sludge consisting of bird excreta. This condition was corrected by discharging the condenser cooling water into the river, but little improvement showed in the quality of the water supply.

Due to normally high ground-water elevation, the mains are inundated with tidal water. This condition together with the fact that there existed several leaks in mains (the town was receiving a revenue from only half the water pumped) indicated that whenever it became necessary to close valves on the mains, which was often done to allow the standpipe to fill, tidal waters entered the mains. A pitometer survey proving too costly, town employes uncovered the mains at odd times and repaired several leaks. This resulted in an improvement in the water in some

sections of the town but samples from oyster packing plants remained unchanged.

It was then found that in almost all packing houses there had been installed bleeder cut-offs to drain the piping above the ground to prevent freezing. This scheme resulted in the rise and fall of tidal water in the service connections between the bleeder cut-offs and the taps. When the cut-offs were changed to a position above the ground water elevation, permitting the pipes to drain but keeping ground water out of the system, satisfactory analytical results were obtained.

The investigators conclude that the repairs to the mains and the corrective change in the location of the bleeder cut-offs were the contributing factors toward obtaining a water of satisfactory quality.—Abstracted from a report of A. E. Goodrich, Div. Engr. Md. State Dept. of Health, dated Mar. 16, 1928, by J. L. Robertson, Jr. Asst. San. Engr., U. S. Public Health Service.

Properties of the Bactericidal Substance in Milk—Several workers have established the fact that fresh raw milk will inhibit for a time the growth of a variety of organisms. Many views have been advanced in explanation of this phenomenon. From the work done by the author and others, it is concluded that there exists in cow's milk a substance which is capable of restraining the growth of certain bacteria for definite periods. With the aim of obtaining more information about the principle, observations were made on: (1) The time of maximum concentration, (2) distribution in the quarters of the udder, (3) reactivation, (4) filtrability,

(5) effect of absorbents, and (6) effect of desiccation. From these observations the following conclusions were reached: The substance is present in the colostrum and milk of the first few days of lactation as well as later. Its concentration varies in the secretion from various quarters of the same cow. Its activity is diminished by heat and cannot be restored again by the addition of active milk. The principle is present in whey and readily passes through the coarsest Berkefeld filter although a considerable portion is retained by N candles. The finest filter (W) completely retains it. It is absorbed by animal charcoal but not by kaolin, kieselguhr, or bolus alba. It can be desiccated and its presence has been demonstrated in one brand of dried milk.—F. S. Jones, *J. Exper. Med.*, 47, 6: 877-888 (June), 1928. Abstr. P. R. Carter.

Ship Fumigation Determined by Observed Rodent Infestation—Report is made of work done to determine if fumigation of vessels need be done in all cases since some vessels may be free from rats. The authors made a study of 100 vessels and concluded that a careful inspection to determine the number of rats present was practicable. A routine procedure was established, after which fumigation was practiced only where inspection showed the need. As a consequence the following conclusions were drawn: (1) More efficient application of regulations regarding fumigation—When agents request extension of routine fumigation period, compliance can be based on the known absence of rats. (2) More efficient fumigation of vessels—Knowledge of the whereabouts of rats and their approximate numbers stimulates fumigators to more diligent effort. (3) Avoidance of expense and delay of shipping by avoiding unnecessary fumigation. (4) Conservation of effort, equipment and material of quarantine station without relaxing essential pre-

cautions against dangerous vessels. (5) Reduction in fumigating personnel through elimination of unnecessary fumigations. (6) Definite stimulation of rat proofing of vessels and encouragement of trapping and other rat eradication measures by steamship agencies striving to obviate cost of fumigation and attendant delay.—C. V. Akin and G. C. Sherrard, *Pub. Health Rep., Reprint* 1149: 861-867 (Apr.), 1927. Abstr. H. B. Foote.

The Disposal of Effluents from Beet Sugar Factories—

The waste disposal problems which confront so many industries present particular difficulties and burdens to the beet sugar industry. The manufacture of beet sugar being limited to about three months of the year throws a heavier charge on the cost of production for a given capital expenditure than is the case in industries which are employed throughout the year. This consideration assumes especial importance in view of the large quantities of water used and waste produced in the manufacture of beet sugar.

The location of beet sugar factories in agricultural districts and on streams of comparative purity renders any contamination of the stream more noticeable and more significant than that which is caused by factories situated in industrial areas in the neighborhood of streams which have already reached a high degree of pollution.

During the early part of the period for which the sugar factory is working, the flow of many streams is low and this may require greater storage facilities for the effluent or a higher degree of purity. The lower temperatures at this time of the year also affect adversely the activity of bacteria and the efficiency of biological methods of purification. In extreme cases, where a stream is frozen over, further difficulties are introduced since it has been shown that in such cases the dissolved oxygen content of an unpolluted stream may fall to as low as 40 per cent of saturation.

Four different wastes are produced by beet sugar factories. Beet carrying and washing water, amounting to about 2 m.g. per 1,000 tons of beets treated daily, is the least objectionable, containing some suspended mineral matter and ordinarily but 20 to 50 p.p.m. sugar, and having an oxygen consumed

value of about 340 p.p.m. This is treated successfully by plain sedimentation for 6 to 8 hours, and by precipitation with lime.

Diffuser battery and pulp press waters, together amounting to 300,000 gals. per 1,000 tons of beets, are more objectionable and more difficult to treat. Combined, these carry 0.6 to 0.8 per cent of sugar and an equal amount of other organic matter. Among methods used with some success in treating these are: Addition of lime followed by carbonation, with or without the mixing in of beet carrying and washing water; plain sedimentation and land irrigation; septic tanks with or without the use of lime; contact beds; trickling filters; fermentation with or without lime to neutralize the butyric acid formed; and activated sludge. Each process has definite limitations.

Filter press lime sludge is readily disposed of by application to land, preferably treated previously with quicklime.

Steffens waste water, the production of which is limited to the United States, is quite objectionable, having an oxygen consuming power of 3,000 p.p.m. and containing all the mineral salts of the beets which may be toxic to fish.—A. J. V. Underwood, *Indust. Chem. & Chem. Manuf.*, 3, 29: 260-265 (June), 1927. Abstr. D. E. Kepner.

Refuse Dumps—The cause of odor from refuse dumps is due either to the decomposition or the burning of organic matter contained in the refuse. The obvious remedy therefore would be to thoroughly separate all garbage and other organic matter for disposal in other ways, such as hog feeding, incineration, or the recovery of the grease and tankage as marketable products.

Separation of garbage from other refuse is commonly practiced and if effectively carried out will be a considerable help in reducing the odor at dumps, but there is certain to remain more or less

organic material adhering to boxes, paper, etc., in the shape of rags, bedding, and the like, or else as garbage that has failed of separation. This material decomposes in the dump during warm weather or catches fire with the ashes, rubbish and the unburned coal and is thus the source of the offensive and far-reaching odors in question. These are a common nuisance in the outskirts of most large cities, depreciating property values and causing general discomfort. They may be carried by the wind under favorable conditions for a distance of several miles. Their complete elimination under ordinary conditions—physical and political—found in most cities is not believed to be practicable.

The following four measures combined with effective separation of other refuse from the ashes will go far to reduce the odor at dumps:

1. All material should be covered with earth without delay. This is the most important measure to be applied.

2. As much as possible of the combustible rubbish (boxes, crates, paper, cartons, etc.) should be burned by itself (preferably in a suitable incinerator) and the dump confined to well-burned ashes.

3. The exposed face of the dump should be beld to the least possible area by dumping at the margin of the fill only and carrying it to the full height, keeping the face covered with earth.

4. Fires should be extinguished at once and not left to smoulder. This can be best done by maintaining a constant water supply reaching all parts of the dump for quenching, but where the dump is too small to warrant the expense necessary for this, much can be done by smothering with sand or earth before the fire extends itself. When once started and after reaching into the body of the dump, such smouldering fires are difficult to extinguish.

Experience has indicated the great difficulty in preventing dumps from becoming nuisances. In addition to odor, there are the objections of the scattering of paper and other light material by the wind and the breeding of vermin and flies. If their use is unavoidable they should be placed in locations remote

from habitations.—Abstracted from a letter prepared by Kenneth Allen, Chairman of Committee on Collection and Disposal of Refuse, Public Health Engineering Section.

Sewage-Polluted Surface Waters as a Source of Water Supply—The suitability of sewage polluted bodies of surface water as a source of water supply is dependent on several factors, including: (a) The character and extent of their pollution, (b) the location of sources of pollution with respect to sources of water supply, (c) the degree of protection to these sources afforded by natural agencies, such as dilution and self-purification, (d) the extent of further purification afforded by artificial water purification, and (e) the practicability and economy of supplementary artificial measures for reinforcing, where necessary, the protection afforded by water purification.

The effects of pollution of sources of water supply are modified by bacterial changes occurring in sewage, by seasonal influences, by dilution and self-purification. In any appraisal of conditions of pollution surrounding a given source of water supply, account also should be taken of the relative sizes of the population groups jointly responsible for such conditions and of their respective locations, on a time-distance basis, with respect to that source.

The average well designed and operated rapid sand filtration plant, aided by chlorination, can produce consistently a final effluent meeting the revised Treasury Department Standard from river waters of the Ohio type hav-

ing an average *B. coli* index not exceeding 5,000 per 100 c.c. For Great Lakes water, the corresponding limit appears to be less than 2,000 per 100 c.c.

Among the supplementary measures currently practiced or proposed for reinforcing existing water purification processes are: (a) long-time storage, (b) double-stage coagulation, sedimentation and filtration, and (c) raw water pre-chlorination.

The total cost of water purification in the United States ranges from 40 cents to \$1.40 per capita annually. Although the cost of sewage treatment may range as low as 40 to 95 cents per capita annually, the extra cost of intercepting sewers, where necessary, may increase the total cost of this measure by from \$1 to \$10 per capita. Exclusive of intercepting sewers, the per capita costs of water purification and of sewage treatment appear to be nearly equal.—H. W. Streeter, *Pub. Health Rep.*, 43, 24: 1498–1522 (June), 1928. Abstr. O. C. Hopkins.

AN OMISSION

In the July issue of the Journal, page 933, appeared an abstract of "Comparison of the Temperature and Bacterial Count of Milk and Foam during certain Stages of the Pasteurization Process." The names of two of the collaborators were inadvertently omitted: C. S. Leete of the Bureau of Dairy Industry, U. S. Dept. of Agriculture, and Prof. L. F. Miller of the University of Minnesota. The abstract carried only the names of H. W. Whittaker and R. W. Archibald, Minnesota Dept. of Health, as authors.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

FIFTH INTERNATIONAL MEDICAL CONGRESS ON INDUSTRIAL ACCIDENTS AND OCCUPATIONAL DISEASES, BUDAPEST

September 2-7, 1928

THE Budapest Meeting of the Fifth International Medical Congress on Industrial Accidents and Occupational Diseases began with a huge reception Sunday night, September 2, 1928, in the Hotel St. Gellert facing the Danube, where the assembling delegates and guests were presented to the officials, both of the Congress and of the Hungarian Government. An accompanying exhibition on industrial safety and welfare was also opened for the week in the Institute and Museum of Social Hygiene by Dr. Joseph Vass, the Royal Hungarian Minister for Public Welfare and Labour. The magnitude of this Congress may be appreciated when we are shown a list of the 2,400 who had registered prior to the first day. The meeting of the International Permanent Committee was held at 9 A.M. Monday in the Academy of Science, centrally located in the city, which building was the headquarters for general assemblages, the secretaries, etc. The address of welcome of Dr. Vass, who is a member of the Catholic clergy, on behalf of the Hungarian Government, was entirely in Latin. At this first meeting the assembly hall and gallery were completely filled with people. Plenary sessions were held Monday afternoon and Tuesday morning, while the sectional meetings began Tuesday afternoon and were continuous, mornings and afternoons, to and including Thursday.

The program was printed in five lan-

guages—Hungarian, German, French, Italian and English; however, the different speakers presented their papers, as a rule, in their native languages. One had opportunity to meet in person many foreign notables in the field such as Dr. Tibor de Verebely, leading Hungarian surgeon and the President of the Congress, Professor William de Friedrich, Vice-President, and Dr. George Gortway, Secretary, and many whose names have been familiar for years. While it may be said that the stress of the sessions was surgical in nature, or, more properly on orthopedic surgery, the meetings were divided into three groups: industrial accidents, industrial hygiene, and general industrial welfare, each having morning and afternoon sessions throughout the period.

Possibly 75 were in attendance from America, the chief party being led by Dr. Fred H. Albee and Dr. Richard Kovacs, President and Secretary, respectively, of the Physician Travel Study Club of America. The names of the Americans on the program, in addition to these two, were Drs. D. Shapiro, Harry C. W. S. de Brun, E. Gidding, E. L. Fisk, Raphael Levy, O. Glogau, New York, N. Y.; Dr. Prather, U. S. Public Health Service, representing Dr. R. R. Sayers and W. P. Yant, Washington, D. C.; Dr. Henry H. Kessler, Newark, N. J.; Dr. R. M. Carter, Green Bay, Wis.; Dr. Orenstein who, while coming from Johannesburg, is really

American; and Dr. Emery R. Hayhurst, Columbus, O.

The sessions on Industrial Hygiene were held in the Institute for Industrial and Social Hygiene, a 6-story building located some distance from the Academy, while those on surgery were held at Dr. Verebely's Clinic, also some distance, but these necessary sorties to meeting places were welcomed as interludes in the intensity of the program. The industrial hygiene papers were mostly upon specific topics such as the diagnosis of lead poisoning, silicosis, fatigue and industrial physiology, rheumatism, neuroses, heart diseases, the special senses, asbestosis, halogen poisons, the hazards of certain trades and poisons, ankylostomiasis, anthrax mercury, pneumokoniosis, brass founder's ague, skin afflictions, syphilis, trauma and others.

A daily bulletin ranging from 15 to 31 pages, printed in five languages, was a convenient feature; also abstracts of all papers were mimeographed and ready for distribution the day following presentation, while an alphabetical directory of all those in attendance, who were registered prior to the meeting, was distributed the first day, likewise an Index Praelectorum of the 176 who presented papers. An unusually complete messenger service kept guests continually notified at their respective hotels of special entertainments and privileges.

Elaborate entertainment was furnished guests in the nature of steamer tours on the Danube, a gala dinner by the government at the Hotel St. Gellert, special receptions to the members of the International Permanent Committee, an evening for all guests in Angöl Park (located on the Island), and a final farewell banquet by the Municipality of Budapest, also at the St. Gellert Hotel.

A diagram of seats was made for all banquets and each was notified in advance of his or his party's table. The entertainment for ladies was especially elaborate, as our wives testified. Additional excursions to the country were also arranged on Friday and Saturday at the end of the week as well as opportunities to visit industries in and about Budapest. Many of the social and excursion events were gratis. The Americans likewise were entertained by Mr. Wright, the American Ambassador to Hungary, with a 5 o'clock tea on Wednesday at his residence.

The transactions of the Congress will be anticipated with eagerness.

The official delegates from the United States were Dr. Fred H. Albee, New York, N. Y., Dr. Francis D. Donoghue, Boston, Mass., Dr. Emery R. Hayhurst, Columbus, O., Dr. Francis D. Patterson, Philadelphia, Pa., and Dr. D. J. Prather, U. S. Public Health Service (all present). EMERY R. HAYHURST

DUBLIN CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH

August 14-20, 1928

WE arrived at this Congress early Tuesday morning, August 14, 1928, and registered at headquarters in The Mansion House, two blocks from our hotel, where we met Dr. T. N. Kelynack, the Secretary, and were introduced to Colonel Sir William R.

Smith, Senior Vice-President and Principal, and Lady Smith. These remained especially solicitous for our welfare throughout the meetings. There were several places to visit in connection with the Congress and we accordingly placed our names on the large

cards hung up for that purpose at headquarters.

The Congress opened with an official reception given by the government at 9 P.M. Tuesday, in The Rotunda of The Mansion House, which was profusely decorated with flags and flowers. It was attended by President William T. Cosgrave and Mrs. Cosgrave of the Irish Free State, and General Richard Mulcahy, T.D., President Designate of The Congress and Minister for Local Government and Public Health, whose wife was in charge of the Ladies' Committee. There were fully 1,000 present at this reception.

The Inaugural Meeting of the Congress took place in The Rotunda of The Mansion House at 11 A.M. Wednesday, where members appeared in their official or academic regalia, including badges and other honors, and formed a procession to their seats, while many of the delegates from foreign countries were assigned seats upon the stage with the officials and guests of the Congress. Telegrams were sent to, and replies later received from H.M. The King, Patron, and H.R.H. The Prince of Wales, Vice-Patron of the Royal Institute. The proceedings were opened by Thomas Murphy, Chief City Commissioner of Dublin, followed by the Rev. Dr. Westrop Roberts, Vice-Provost of Trinity College, Dr. D. J. Coffrey, President of the National University College, Dublin, Dr. W. A. Winter, President of The Royal College of Physicians, Ireland, Dr. T. E. Gordon, President of The Royal College of Surgeons, Ireland, Dr. E. Magennis, President of the Apothecaries' Hall of Ireland, and Sir Thomas Oliver, Vice-Chancellor of The University of Durham, and Chairman of the Council of The Institute. A number of overseas delegates addressed the meeting, representing Australia, South Australia, India, the Settlement of Shanghai, and Switzerland, and the writer spoke a few

words as a delegate from some American institutions. The next meeting place was announced as Zurich, Switzerland.

A luncheon was then extended to the members of the Congress by the Messrs. Arthur Guinness, Son & Co., under the chairmanship of Sir John Ramsden, its Chief Medical Officer, and followed by a trip through the enormous establishment.

We took the Peamount Sanatorium trip, 12 miles from Dublin, in the afternoon where several hundred tuberculous children are being treated according to the most modern methods, under the auspices of the Marchioness of Aberdeen and Temair, who has actively sponsored anti-tuberculosis work for years in Ireland. Other trips also were arranged for that day—to the Cappagh Open Air Hospital for Crippled Children, Newcastle Sanatorium, and one to the Crooksling Municipal Sanatorium, all located a few miles away from Dublin. We likewise greatly enjoyed the visit to Trinity College the latter part of that afternoon. For the evening, tickets were provided to the Irish National Theater for one of the finest plays we have seen—one characteristic of Irish life, and by an Irish troupe—"Professor Tim" (by George Shiels).

Sectional meetings began Wednesday afternoon, and continued during the meeting with long morning hours (9:30 to 1:00) and short afternoon hours (2:30 to 4:00).

Section I of the Congress was devoted to State Medicine and presided over by Registrar General E. P. McCarron and Sir William Milligan, there being 13 papers listed under its general sessions. The three sub-sections were (1) Municipal, County and Port Sanitation, under Dr. E. F. Stephenson and Alderman William Muirhead; (2) Epidemiology, under Sir John Moore, Dr. Thomas H. C. Stevenson, and Dr. Matthew J. Russel, with 10 papers, and (3) Housing of the Working Classes, and

Town Planning, under Dr. C. W. Dwyer and Professor L. Patrick Abercrombie, with 7 papers.

The trend of papers on State Medicine concerned malignancy, administrative public health matters, alcoholism, nervous diseases, industrial hygiene, milk, town planning, and small house construction.

Section II was on Bacteriology, Pathology and Biochemistry, and presided over by Dr. W. D. O'Kelly and Dr. James M. Beattie, with 8 papers, concerning research and various bacterial diseases.

Section III was on Maternity and Child Welfare, and School Medical Inspection, and presided over by Dr. J. A. Harbison and Professor A. Louise McIlroy, with 23 papers, concerning midwifery, social hygiene, and child and natal hygiene in various phases.

Section IV, on Production and Control of Milk and Food, was presided over by Professor J. F. Craig and Dr. Gerald Leighton, with 10 papers upon the questions of safe food supply, parasites, "wholesome milk," butter and margarine.

Section V, on Tuberculosis, was presided over by Sir William J. Thompson and Dr. P. C. Varrier-Jones, with 15 papers touching upon the prevention, sanatorium treatment, and education of tuberculous patients, and an interesting address upon the "Humor and Pathos of a Tuberculous Campaign," by the Marchioness of Aberdeen and Temair, also a couple of fine films upon the Papworth Village Settlement where perhaps 1,000 tuberculous workers with their families are self-supporting.

The scientific meetings closed with the Friday morning sessions.

Thursday noon a luncheon was given in the Royal Hibernian Hotel to some 80 persons connected with the Congress

by The Right Hon., The Viscount Leverhulme. That afternoon visits were made by the women to certain municipal undertakings and housing schemes in Dublin while a sectional meeting was in session. The latter part of the afternoon we visited University College. On Thursday evening the Congress Banquet was held in The Mansion House, some 500 guests being present, and the chair presided over by Sir Thomas Oliver with short addresses by a number of prominent persons in health, official and religious circles. Among others was His Grace, The Most Rev. The Archbishop of Dublin, who proposed the toast of The Royal Institute of Public Health in a stirring address which was responded to by Col. Sir William Smith, who referred especially to the origin and subsequent progress of the Institute.

At the Garden Party at The Vice Regal Lodge given by Governor General and Mrs. James McNeil, at 4 P.M. Friday, there were some 1,200 persons present. Following the formal introductory program, the seven Americans present were again introduced by Sir William J. Thompson, Honorary Secretary of the Congress.

On the Saturday and Sunday following, excursions were arranged, even to distant parts of Ireland. Also on Sunday some of the delegates attended the morning services at St. Patrick's Cathedral.

The final meeting of the Congress was held at 9 A.M. Monday in The Mansion House, where universal satisfaction and appreciation of the Dublin arrangements were formally declared. We, however, left early Saturday morning for a trip to Killarney Lakes, Cork, and Blarney Castle.

EMERY R. HAYHURST

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Recent Food Infections—This editorial discusses an outbreak of enteric fever, 90 cases being under treatment in London hospitals on August 14. The symptoms were mild with no vomiting and diarrhea but constipation with many manifestations of rose spots. Two cases were severe and 1 death was reported at Epsom. The organism held responsible was *B. paratyphosus B*, presumably distributed in food. Cream is under suspicion and the view is held by some that the withdrawal of the permission to use boric acid preservative is responsible. It is contended that this is unlikely since cream is produced from milk and permission to use boric acid in milk has not been a fact since 1912. It is further pointed out that the public has confused the paratyphoid outbreak with cases of food poisoning and that the rapid onset, accompanied by vomiting and diarrhea and frequent prostration indicative of food poisoning, is in marked contrast with the slow and mild development of the symptoms caused by *B. paratyphosus B*. All of these causative agents, however, are similar in that they belong to the Salmonella group of organisms. In England the *B. paratyphosus A* organism does not occur, C is occasionally found but the B type is common.—*Lancet*, 2: 334 (Aug. 18), 1928.

Rickets in Rats—Comparisons of Effects of Irradiated Ergosterol and Cod Liver Oil—Rats fed on Sherman diet B, when 28 days old were placed on Steenbock and Black's high calcium-low phosphorus diet 2,965 plus 10 per cent lard. This diet contained 1.07 per cent calcium and 0.178 per cent phos-

phorus. The rats were kept on this diet for 21 days, after which 2 per cent of the lard was replaced by cod liver oil, or irradiated ergosterol in olive oil, both being given separately and not mixed with the diet. The amount of ergosterol given was equivalent to 0.01 mg. per rat per day. After 14 days the animals were killed and autopsies showed intramuscular hemorrhages in 2 of the rats receiving ergosterol. The animals, studied as to (1) blood serum analyses, (2) histological examination of the bones, (3) bone analyses and (4) metabolism of calcium and phosphorus, showed that marked cure of rickets in rats is secured in 2 weeks by cod liver oil and by 0.01 mg. daily of irradiated ergosterol. The cure is accomplished without great increase in the retention of calcium or phosphorus as is shown by metabolism studies. Histologically the bones show substantially the same condition with the cod liver oil as with the ergosterol supplement.—Alfred T. Shohl, Helen B. Bennett and Katharine L. Weed, *Proc. Soc. Exper. Biol. & Med.*, 25: 551 (Apr.), 1928.

Acid Drinks and Enamelled Vessels—This article discusses a report by the assistant medical officer of health for Newcastle-upon-Tyne of an outbreak of poisoning following the consumption of an ice drink prepared in an enamelled vessel. The firm desiring to provide a refreshing beverage for its employes during a hot spell undertook to make "lemonade," the acid ingredient of which was tartaric acid. This was dissolved in hot water in enamelled buckets purchased for the purpose, the rather concentrated acid solution remaining in

the buckets over night. It was found that the enamel on these buckets had been attacked so that it could be removed with the finger. The enamel on these pails contained antimony oxide equivalent to 5 per cent of the metallic antimony. Antimony was also found in the "lemonade" taken from the pails to the extent of 0.013 per cent metallic antimony. This amount, according to the medical investigator, is equivalent to 1.52 gr. of tartar emetic in a 10 oz. tumbler; so that drinking one-third of a tumbler might be expected to result in definite symptoms. No other heavy metals being found in the beverage, the conclusion is drawn that the poisoning was due entirely to the antimony. Further comment is made that the buckets used for this purpose were not intended for food purposes by the manufacturer and that in those circumstances the enamel is so adjusted that ordinary acid solutions used in the household will not remove appreciable amounts of the glaze. It is suggested that containers of such character should be sufficiently labeled that they will not be used for food or drink purposes and that such outbreaks be given publicity for warning purposes.—*Lancet*, 2: 337 (Aug. 18), 1928.

A Bacteriological Study of Salad Dressing—A bacteriological examination is reported of 15 brands of mayonnaise, 12 of other salad dressings, 6 of olive mayonnaise, and 6 of olive relish. With the exception of a few samples of homemade mayonnaise only commercial products were studied, and the condition of all of the samples was good when the cans were opened. Of the entire number of cans, only 4 were found to contain anaerobes, and these were non-toxic. The number of aerobic organisms varied from 0 to 17,400 per c.c. The largest percentage of sterile cans was found among the salad dressings other than mayonnaise. These con-

tained a starch paste, and it is thought that the heat used in preparing the paste and the acidity of the product were the chief facts contributing to sterility. The most probable source of contamination is considered to be the egg yolks. From 12 cans, sporeforming rods with morphological and cultural characteristics similar to *B. subtilis* and *B. mesentericus* were isolated. *B. coli communior* when introduced in broth cultures into the various foods disappeared rapidly. *B. subtilis* remained viable for a longer period of time.—F. M. Bachmann, *Wis. Acad. Sci. Arts and Letters, Trans.*, 23: 529-537, 1927. *Abstr. Exper. Sta. Rec.*, 59: 488 (Oct.), 1928.

Growth and Reproduction on White Bread with Various Supplements—The rations used in this experiment contained 70 per cent or more of bread made from high grade patent flour. In order to get representative results 3 kinds of bread were used—a commercial bread containing some milk, as well as lard, sugar, salt and yeast; and two specially prepared and containing the same amounts of yeast but one made with water and the other fluid milk. Rats 28 days old were placed on this experimental ration. Six series of experiments were conducted using for supplements whole milk at two different levels, egg, carrot, spinach, almond and lean beef. Charts are given showing the growth curves on the different diets. On a diet of dried bread 70 per cent and dried whole milk 30 per cent, there were normal growth, good health and reproduction. Similar results were obtained with dried bread 70 per cent and dried egg powder 30 per cent, 4 females bearing 68 young, 12 of which were placed on the diet of the mother rats at 28 days. Half made normal gain for 3 to 6 months, but the remainder showed signs of general weakness, nasal hemorrhages and rickets and

3 died within 6 weeks. Results with bread 90 per cent and milk 10 per cent were similar to bread 70 per cent and carrot 30 per cent. Growth was poorer than with egg or 30 per cent milk. Neither the bread and almond nor the bread and spinach diet was able to maintain the animals in health. The poorest records were made with bread and lean beef. No marked differences were shown between the kinds of bread used, and the best results were obtained on bread 70 per cent and milk 30 per cent, and on bread 70 per cent and egg 30 per cent.—Mary Swartz Rose and Grace MacLeod, *J. Nutrition*, 1: 29 (Sept.), 1928.

The Calcium of Cheese—An experiment was conducted to determine whether commercial cottage cheese, "a sour milk cheese," is really lower in calcium than other common cheeses—the rennet cheeses. The cheeses used were three different samples of colored American Cheddar, one white American Cheddar, three domestic Swiss, and one imported Swiss, two Dixie cottage cheese, and three of Borden's cottage cheese. The calcium was determined by the Shohl modification (*J. Biol. Chem.*, 50: 527–536, 1922) of the McCrudden method, precipitating the calcium from solution of ash as oxalate at pH 4.8 to 5.2, igniting and weighing as calcium oxide. It was found that the two rennet cheeses, Swiss and Cheddar, have approximately 14 and 9 times as much calcium as the cottage. The calcium is not only higher in the rennet cheeses but higher in proportion to the protein—for every 100 gm. of protein there are 3.37 gm. in the Swiss, 2.83 gm. in the Cheddar and 0.62 gm. in the cottage cheeses.

Cottage cheese, therefore, is a poor source of calcium and not a rich one as usually considered.—Katharine Blunt and Emma Sumner, *J. Home Econ.*, 10: 587 (Aug.), 1928.

Nutritive Value of Haddock and Herring—Young growing rats 21 to 25 days old and 40 to 50 gm. in weight were used in this experiment. The haddock was bought in small amounts in the open market and after being freed from the head and viscera was made into meal which contained many small bones. The herring was also made into meal which contained a small amount of bone material. Samples of the herring and haddock were analyzed for content of fat, nitrogen, moisture, ash, Ca and P. The herring and haddock were fed in a series of diets, each kind being fed alone and then in diets variously supplemented. Charts are given showing the rate of growth for the animals. When fed haddock alone and with the addition of salts, the animals developed ophthalmia, indicating a low vitamin A content. With the addition of vitamin A in the form of butterfat the animals improved rapidly for a short time, but after 2 months the animals died. Death was due to vitamin B deficiency, since it was found that the addition of 3 per cent yeast prolonged life. Herring free from bone contains sufficient vitamin A to prevent xerophthalmia but was found deficient in minerals and vitamin B. Herring proteins at the levels of 9 and 15 per cent were not adequate for the well-being of the second generation. Tables are given showing the supplementary value of fish proteins for cereal, legume seed and liver proteins. Herring and haddock were found to be poor supplements for the proteins of navy beans and peas, haddock being the better of the two. Both fish proteins have a supplementary value for the proteins of oats and wheat, herring having a higher value than haddock. The supplementary value of herring compares favorably with that of steak, liver and kidney and is higher than that of haddock.—M. C. Kik and E. V. McCollum, *Am. J. Hyg.*, 8: 671 (Sept.), 1928

Commercial Acidophilus Products—The investigation reported which was concerned with laboratory analyses alone is intended to throw some light on a number of commercial acidophilus products which might be expected to have therapeutic value. Eight such products were included in the investigation: 7 of these were milk and the 8th was a broth culture. By plating on whey agar, casein digest agar, meat infusion agar, and in the case of one product, tomato extract agar, and by incubating the plates at 37° C. for 3 days in air and in an atmosphere of 5 to 10 per cent carbon dioxide gas, the numbers of viable microorganisms were ascertained. Whether these organisms were *B. acidophilus* of strains known to have therapeutic value was determined by comparing their reactions in various sugar media with those of a stock laboratory strain of proven therapeutic value.

As a confirmatory test the critical surface tension in dynes was determined for each strain isolated. Five of the products examined were prepared in the East and were examined very soon after manufacture. Three products were obtained from the West and were shipped to New York City by air mail.

It was found that the broth culture which purported to be *B. acidophilus* was *B. bulgaricus*, and the maximum number of viable organisms was 40,000,000 per c.c. Of the 7 milk products examined 5 bore information on the label as to the number of viable organisms claimed. Of these 5 products only 2 fulfilled these claims as to numbers present, and in both cases the cultural reactions of the strain of *B. acidophilus* present were not identical with those of the stock laboratory strain, and were consequently considered

by the investigators to be of doubtful therapeutic value. Three products were found to contain one-half or less than one-half the numbers claimed, and in 2 of these products the organisms present differed from the stock laboratory strain of *B. acidophilus*. One product examined contained authentic *B. acidophilus*, the maximum number found being 57,000,000 per c.c. The label of this product bore no claims as to numbers. One product, the label of which bore no claims as to numbers, contained a maximum of 170,000,000 organisms per c.c. These organisms were identical with the stock laboratory strain.

It is pointed out by the authors that at present there is no definite figure known for the minimum number of viable acidophilus bacilli requisite for therapeutic results. Attention is directed to the need for scientific experimentation to establish such a standard.

In the experience of the authors a daily dose of 1 quart of acidophilus milk containing not less than 100,000,000 organisms per c.c. is necessary to alleviate severe chronic constipation or acute diarrhea within 2 weeks. They add that a lesser number of viable organisms ingested for a longer period of time may be, in all probability, beneficial. It is recommended that the labels of all acidophilus products bear the following information:

- (a) Date of manufacture
 - (b) Minimum number of viable organisms (*B. acidophilus*) at date of manufacture
 - (c) Minimum number of viable organisms (*B. acidophilus*) at time of earliest possible sale under normal conditions
 - (d) Date of expiration
 - (e) Minimum number of viable organisms (*B. acidophilus*) at date of expiration
 - (f) Type of *B. acidophilus* predominating—

J. A. M. A., 91: 1187 (Oct. 20), 1928.

CHILD HYGIENE*

MERRILL E. CHAMPION, M. D.

Studies on Infant Mortality—West coast cities have for some time had a lower infant mortality rate than eastern and southern cities, chiefly because in the race for health all cities do not start from the same base line. This is the conclusion of Dorothy Holland, Ph.D., and George T. Palmer, D.P.H., in a paper given before the American Child Health Association.

One of the first steps in finding out why one section of the country should be uniformly successful in preserving infant lives is to discover how the cities with low rates differ from the cities with high rates, Dr. Holland points out. Do the weather records show more sunshine in the low rate cities? do they have less poverty? or are they better instructed in health matters? Sunshine, temperature and other weather facts for each city are to be found in weather records. Census reports likewise give data on the amount of illiteracy; economic status is measured by the number of unskilled workers, nationality, etc.

Dr. Holland was able to secure the statistics for about twenty-five different influences which are believed to have a bearing on infant mortality. By mathematical means the importance of these was tested for approximately 100 cities for the years 1921 to 1925.

The peculiar features of the cities with low infant mortality were that they had relatively little rainfall, practically no illiteracy, and were of a relatively high economic status, as indicated by small percentages of unskilled workers and low percentages of negro popula-

tion. The proportion of total foreign population did not exercise a marked influence one way or the other although the cities with a generous sprinkling of Scandinavians usually had low baby death rates.

From the relationships thus disclosed it was then possible to predict mathematically what a city's rate would be after making due allowance for these various favorable and unfavorable influences.

While the method worked out is experimental and deserves further study, Dr. Holland is hopeful that it will eventually be of material assistance to the public health profession in determining what rates can be expected of a city considering its external health advantages and disadvantages. The city with natural handicaps will not be expected to achieve the record of another with natural advantages unless very great effort is exerted. On the other hand, the favored city will have less excuse for a high infant death rate.

When fully worked out the table of predicted rates will reveal what cities have rates higher than the predicted rates and what cities have lower rates. This information itself will be of the greatest value as a basis for further search to find the causes responsible for the deviation of these cities from the expected rates.

The Place of Sickness Records in the School Health Program—"The results of a 4-year study of the illnesses among school children of Hagerstown, Md., seem to show that younger children suffer illness slightly more frequently than older children, and girls

*The abstracts for this month deal with papers given before the American Child Health Association on the occasion of its joint session in October with the American Public Health Association in Chicago.

more frequently than boys," according to Selwyn D. Collins, Ph.D., Associate Statistician, U. S. Public Health Service.

Respiratory diseases caused 46 per cent of all the illnesses occurring in the 4-year period, or an average of slightly more than 1 respiratory attack per child per year. Of the 16,475 respiratory attacks, 66 per cent were reported simply as colds, 21 per cent as tonsillitis or sore throat, and 10 per cent as influenza or grippe. "Sore throat" and "grippe" were the more frequent names used in the last two groups. Most of the influenza and grippe occurred in two outbreaks which attained their peaks in March, 1922, and February, 1923, respectively.

Next in frequency to the respiratory diseases comes headache and third is "biliousness" and similar terms. Fourth in the list come the communicable diseases, including measles, mumps, whooping cough, chicken pox, scarlet fever and diphtheria.

Public health and school officials are very active in the prevention of communicable diseases but are doing little or nothing about the greater problem of the respiratory diseases, except those relating to the tonsils. The size of the respiratory problem or the absence of any solution for it, however, is not confined to the school but is true among industrial workers and the general population.

Colds are very frequent at 6 years of age but decline to a minimum at 11 years of age or not much more than half the rate at 6 years. After 11 years, the rate rises slightly. Influenza and grippe are reported more frequently among the older than among the younger children. Tonsillitis and sore throat are relatively low at 6 years, rising to a maximum at 11 years, after which the curve declines considerably. The curve for headache is somewhat similar to the tonsillitis and sore throat

curve, its peak coming at 12 years of age.

Digestive disturbances increase slightly with age, the maximum coming at about 12 years, after which there is a slight decline. Toothache rises to a maximum frequency at 9 years with a tendency toward a very slight decline thereafter.

Accidents rise to a peak at 12 years of age. Automobile and other street accidents would probably be more frequent among the younger children but the data here classified as accidents include many minor injuries such as a sore finger, hurt possibly in playing ball, and other such minor conditions.

While the relation of sickness to many physical defects was not gone into, there have been collected considerable data on sickness from certain causes in relation to the condition of the tonsils. Tonsillitis and sore throat, of course, show the largest differences in the sickness rate, the rate for the children with removed tonsils being less than half that for children with defective tonsils. Colds are also slightly more frequent among children with defective tonsils than among the other two groups.

Sickness and Absence Records in the School Health Program—Is it worth while in the promotion of the health of America's children for schools to keep sickness absence records? O. B. Nesbit, M.D., Director of Medical Inspection of the public schools of Gary, Ind., believes that keeping such records is immensely valuable. Gary has the distinction of being the only city in the United States where a health program with a full-time medical officer has been a part of the school curriculum from the very first development of the school system.

The school nurse makes out a personal history record card when a pupil enters the school, and files this for a

working record. Dr. Nesbit says: "These data are available for transfer to the health record card." The school nurse also sees and examines any pupils or school employes taken ill at school and "excuses" them if in her judgment such persons should go home.

The nurse "excludes" from school any pupil suffering from communicable diseases, vermin, parasitic skin diseases, etc., upon direction of the school physician. The nurse may readmit "head" cases, and skin troubles, at will. She readmits chicken pox, smallpox, diphtheria and scarlet fever cases only on permit from the city health department, measles after 2 weeks, and whooping cough after 4 weeks.

In the 4 years during which the school has been attempting immunization against smallpox, scarlet fever and diphtheria, 1924 to 1928, there has been a decided drop in the number of cases and also in the number of days lost.

During the past 10 years, 1,688 cases have been excluded from school. It would seem a worth while service to remove these cases from association with well children, but contact out of school was probably very little restricted except in the quarantined cases.

Result of the National Congress of Parents and Teachers 1927 Summer Round-up of Preschool Children—Discussing the Summer Round-up of preschool children, as it is being pushed by the National Congress of Parents and Teachers, Máry E. Murphy, of the Elizabeth McCormick Memorial Fund of Chicago, stated that continuous medical supervision of the child from

birth to school age and the instruction of all parents in child care is the goal.

"From a group of 102 local associations in 22 states taking part in 1925, the movement has grown until, during the year 1927, 2,120 groups representing local communities in 44 states participated. Among the 448 associations which met all the requirements of the round-up there were 13,768 children examined. Among these, 17,857 defects were found of which 6,262 were corrected, or over one-third.

"Thirty associations secured the correction of more than 75 per cent of the defects discovered. Of these, 5 scored 100 per cent, while 9 passed the 90 per cent mark. Seventy-nine associations made a record of between 75 per cent and 50 per cent. Of these associations all met the requirements of a spring and fall examination and an official report to the National headquarters.

"The slogan with which the movement was launched, 'Let Parent Pride Put Parent Power to Work,' expresses tersely its real significance. It is built upon a common interest of men and women organized around the school for the benefit of the children in the school and the community. With a sense of responsibility which the home should assume as its share in the common project of home and school, the parents of the local associations have striven to send to school an entering class of children physically prepared.

"This great organization with its 20,000 units representing every economic level provides a strategic avenue of education into more than a million homes."

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

MENTAL HYGIENE AS A PART OF PUBLIC HEALTH NURSING

The October number of *The Public Health Nurse* is devoted largely to a discussion of the meaning and place of mental hygiene in public health nursing. Several urban public health nursing associations have already incorporated mental hygiene in their programs, trying out various methods of administering this phase of their work and educating the workers.

Dr. George K. Pratt, in a leading editorial, speaks of the strategic position of the public health nurse for detection of mental and emotional difficulties in early stages. The nurse who is trained in knowledge of mental conditions acquires an "increased understanding of the true nature and sources of her personal problems. Such personal understanding is, in turn, followed by a clearer comprehension of her patient's difficulties, with a consequent increase in her efficiency as a nurse."

Mental Hygiene Commentaries

Mental hygiene is not something new and alien which is added to hygiene; it is hygiene adequately conceived. Mental nursing is merely nursing adequately conceived. . . . The physician and nurse who are in contact with the infant after the departure of the obstetrician have an opportunity not only of seeing that the child gets the right formula and puts on weight at the recognized speed, but of supervising the general training of the child with regard to the first tests of its adaptation to the new world.

In regard to many school pupils, problems will come up that are not merely pedagogic problems, and the question is whether these will be handled in a summary, disciplinary way or whether they will be studied adequately and intensively by one who has been specially prepared for this sphere of work. This latter means that the school physician

and the school nurse shall have comprehensive training in the field of nervous and mental disorders and be familiar with the problems that are raised by difficulties in the instinctive and in the emotional life.

Interest in work, satisfaction from successful functioning and from due recognition, an understanding of the rôle which the individual worker plays in the general industrial machine, the absence of a feeling of injustice or grievance, these are a few of the factors which favor the mental health of the individual worker. In some plants while efficiency is assured by means of vocational tests and job specifications, by the use of production charts, by attention to problems of fatigue, and to need of change, at the same time the health and happiness are guarded by the social assimilation of the incoming worker, by definite friendly advances of chosen fellow workers, by some explanation of the rôle of the individual worker in the general industrial machine, by kindly contact with the home, if necessary, through industrial nurse or social worker. Industry, primarily interested in efficiency, may come to be one of the great cultural influences.—C. Macfie Campbell, M.D., *The Prevention of Mental and Nervous Disorders, Canada Lancet.*

The public health nurse must learn to distinguish between modifiable and unmodifiable human material. This is a distinction which doctor and nurse and social worker and teacher must learn to make, and they learn it through the painful method of trial and error in daily experience. Until we learn this lesson, we shall waste a great deal of energy and expose ourselves to ideas of inferiority and attitudes of depression. This point of view may seem heartless. Yet experience has shown that attempting to force a person to believe what he doesn't want to believe is futile. The harvest of human distress is great and the reapers are too few. As such it is an absolute necessity for us to conserve our energies for activities in which there is some opportunity for accomplishment.

You who come in contact so intimately with these gnawing problems of human lives, I would urge to work upon such common needs of mental hygiene. If in your own mind talking with a psychiatrist is synony-

mous with a charge of insanity, your clients will feel the same way. If you allow yourself to yield to the facetiousness that expresses itself in "I guess I'll go and have my head examined," you may stand in the way of someone who needs our helpfulness. The persuasion of someone to go to the right physician and talk things over is not a task, if you yourself understand the nature of the mind, and its expression in behavior. There are few of us who do not need to recover from mind shyness. The word psychology is a commonplace in our conversation, but it usually refers to the psychology of the other fellow. It is one thing to take courses of study and do reading on Instinct and Habit; it is another to recognize emotional mismanagement in ourselves that causes us to be physically ailing, or bitter and cynical, or petulant and over-critical.

From what I have seen of the nurse in training, and the nurse in public health, I believe that she is not only competent to understand and use these principles dealing with the relation of behavior to health, but I feel that her work is seriously handicapped by a lack of training in this branch of medical science. To make possible such practical experience for you who go out to bear the burden and heat of the day should be one of the greatest causes to which nursing education can direct its energy.—Esther Loring Richards, M.D., *The Meaning of Individual Adaptation in the Field of Health*, Shumway Memorial Lecture of the Visiting Nurse Association of Chicago.

One of the serious dangers at present is that we shall neglect all traits except intelligence, and regard a child as a tall or short intellect mounted on legs. We speak of "mental age" and "mental ability" when what we mean is intelligence age and intelligence ability. There are many kinds of mental ability, such as ability to control one's self, or to appreciate art, or learn arithmetic. Intelligence is but one of them, and by no means always the most important.

If we are going to "send the whole child to school," let us observe the whole child, even if we cannot measure each fraction of him accurately. And let us plan for the mental health of the whole personality rather than for only a portion of that personality.

Planning for mental health would also lead us to place a heavy emphasis, more than is yet common in our schools, on self-mastery, and on the acquisition of those emotional social qualities which, though of lesser value, perhaps, in dealing with the material environment, are so necessary in making human contacts.—Daniel Wolford La Rue, *Mental Hy-*

giene in Curriculum Making, The Nation's Schools.

Public Health Nurse, XX, 10 (Oct.), 1928.

Diphtheria is Still Declining— Since 1900, a decline in the death rate from diphtheria has been noted in the 10 states of the original registration area. The decline was rapid at first but, around 1915 and 1920, it became more gradual. In 1922, a further drop to about 8 deaths per 100,000 population occurred with such suddenness that it seemed necessary to account for it by some new factor; perhaps partly improved medical and nursing care, undoubtedly partly the use of antitoxin immediately upon diagnosis of the disease.

No corresponding drop in the number of cases of diphtheria was noted until after 1922. It was about this time that toxin-antitoxin was introduced and adopted rather generally, and there seems adequate ground for feeling that the use of this immunizing serum has materially affected the incidence of the disease.

It is somewhat disturbing to advocates of the toxin-antitoxin treatments to find that during 1927 and 1928 the number of deaths and the number of cases have both been on the increase again. There are two ways of accounting for this. Not all the susceptible individuals have been immunized in spite of the accepted effectiveness of toxin-antitoxin; so it is quite possible for the disease to develop among this untreated group. Also by study of diphtheria records for the past 30 years, it is found that the disease has occurred in waves, reaching the peak of greatest prevalence about every 7 years.

The increase of 1927 and 1928 is in direct accord with the preceding pattern of incidence. However, since it started from a much lower level, there is little

doubt that the peak will be much lower than in any preceding period.

Experience teaches us that as a disease comes under more complete control, its endemic prevalence reaches lower and lower levels and its epidemic waves grow smaller and smaller until it becomes a "rare" disease. If the battle against diphtheria is continued without faltering, by use of the weapons at our command we can confidently expect this result in the course of the next generation.—

Edgar Sydenstricker, Is Diphtheria Still Declining?, *Survey*, LXI, 2: 77 (Oct. 15), 1928.

Light Therapy—In these days when ultra-violet light is in danger of becoming the latest fad, we are grateful for definite facts about its value and its limitations. Dr. Winthrop M. Phelps tells about the various forms of light therapy in an extremely interesting article.

"Light" itself is to be considered as "a constant stream of radiation or waves which constitute the electromagnetic spectrum." These waves vary in length from crest to crest, and the form of light produced depends on the wave length. At one extreme are the very long ones which are known to us as radio waves; the next shorter are heat waves, then the visible color rays; shorter than the color rays are the invisible ultra-violet or X-rays, and shortest of all the rays from radium.

Most light sources produce varying combinations of the visible and invisible rays, but we are conscious only of those portions which produce immediate sensory reactions, such as heat or color. Except for the radio waves, all have a certain effect upon growth and health, the ordinary light waves being so constantly a part of our environment that we are unconscious of their significance to our well-being.

The therapeutic value of the heat or infra-red rays and ultra-violet rays is the chief subject of discussion in this paper. Concentrated heat rays, by

means of reflected electric light bulbs or more complicated apparatus, are used to improve circulation locally by vasodilation, to produce muscular relaxation, and to give certain analgesic effects in pain.

Ultra-violet rays are produced in connection with most visible light but, because of the fact that they do not penetrate ordinary glass, their value is lost from such sources as electric light bulbs. A quartz container will allow effective radiation of the ultra-violet rays. Although body burns due to over-exposure to ultra-violet rays are not usually serious, the sensitiveness of the eyes is so great that they should always be protected by a shield while the treatment with ultra-violet rays is being given.

The knowledge of the positive value of ultra-violet rays in specific disease conditions is at present not extensive. Rickets is unquestionably helped, and the best source of the desirable rays for treatment of rickets is a fresh mercury-vapor arc enclosed in a quartz tube.

The ultra-violet rays do not penetrate the skin deeply; so they are of little value in direct concentration over diseased areas lying in the deeper tissues. The general exposure of the body surface to the rays, however, seems to speed the recovery no matter where the underlying pathology is. Certain skin conditions are improved by ultra-violet rays, but others seem to be made worse. Ultra-violet light does have a definite effect of improving muscle tone. Most other attempts to improve diseased conditions by this means have shown no positive results.

There has been much discussion, pro and con, as to the value of ultra-violet light in the treatment of tuberculosis. It is generally accepted that the light rays as combined in sunlight are more effective in the treatment of tuberculosis than any concentrated artificial light rays. The nearest artificial approach

to whole sunlight is the "white-flame carbon arc." It requires no glass cover, but it must be produced through special heavy electric wiring in order to contain all the rays necessary. It is considered useful in institutions or offices for treatment of bone or glandular tuberculosis but impractical for use in the home. Certain disadvantageous effects of the white-flame carbon arc have been noted in cases of pulmonary tuberculosis, so that on the whole the mercury-vapor arc is at present considered a safer substitute for real sunlight for such cases.

Emphasis is placed on the need for being sure that the apparatus is actually in condition to give the desired results, whether it is a plain electric light for heat waves, mercury-vapor arc for ultra-violet light, or white-flame carbon for the whole spectrum.—William M. Phelps, M.D., *Light Therapy*, *Am. J. Nurs.*, XXVIII, 9: 875 (Sept.), 1928.

The Changing Status of Health Publicity—In the last thirty years the total amount of sickness and death has been decreased by one-third, due almost entirely to such specific measures as sanitation, quarantine, and immunization—the reduction occurring in such diseases as typhoid, diphtheria and smallpox. It still remains to find measures which will reduce sickness and death from cancer, heart disease, and common colds.

In very early days health regulations were considered a part of the religious code, and so were easily enforced. Quarantine and inoculation against smallpox were enforced through legal enactment. But with the beginning of the last century, and the awakening to the problem of tuberculosis, police power was found ineffective, and a

health education program began to develop. It is through the education of mothers that infant mortality has been so far reduced.

However, organized education in the laws of personal hygiene must be supplemented by personal instruction of individuals and by periodic health examinations. The principal objectives of a health education campaign are summarized by Dr. Hiscock as "first, the avoidance of external conditions dangerous to life, as accidents and germ diseases; second, the development . . . of artificial immunity through . . . sera and vaccines; third, the inculcation of the principles of hygiene; fourth, the development of the conception of preventive medicine, through the employment of physicians for early diagnosis . . . and guidance in the application of laws of healthful living. . . ."

There are innumerable media of publicity by which the people can be reached—the press, radio, movies, exhibits, public addresses. The material used for such publications must be authentic, interesting, stimulating, simply expressed, and timely.

Many fields offer excellent opportunity for study and publicity of results—social hygiene, cancer, heart disease, tuberculosis, child health. Much has already been published, but there is still much left to be done in acquainting the public with methods of reducing sickness and preserving life. It has been estimated that if existing knowledge of measures for health promotion were generally applied, at least ten years could be added to the average life span.—Ira V. Hiscock, *The Changing Status of Causes of Death and Sickness, from the Publicity Standpoint*, *Proceedings of the National Conference of Social Work*, 1928. C. E.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

What Does the Public Think about It?—Syracuse is on the way to trying some form of evaluation of health education material. The discussion which follows appeared in the October–November issue of *News Bulletin* of the Committee on Publicity Methods. Since so many JOURNAL readers are interested it seems fair to reprint it in full.

We have been considering for some time, in Syracuse, the possibilities of evaluating some of our publicity and are somewhat puzzled as to just how to proceed.

Over a year ago we tried an "Ask Me Another" contest over the radio to see how valuable that avenue of health education was, finding it rather successful.

We are not so much concerned with what the public thinks of our material, as suggested on page 10 of your September *Bulletin*, as we are with the educational value of the message we give. We believe, of course, that the more attractive the method of presenting the message the better is the chance of having its contents fully absorbed by the public. To that extent we are interested in what people think about our stuff. Our proposed plan is to circularize by mail perhaps 1,000 citizens, asking certain questions on health, then tabulating their answers. After this has been done we would distribute a street car card answering the questions previously asked and about two weeks after that circularize another 1,000 persons with the same questions and compare the results of the two groups. In such an effort we would, of course, attempt to avoid all newspaper items on the subject, as well as radio talks.

Having thus possibly obtained the increased knowledge caused by the car card, we would try the same principle with newspaper articles, omitting all radio talks and posters. It is our belief that having done this by three or four methods, such as car cards, posters, radios and newspapers, we would be able to decide which

offers us the best opportunity of presenting our health messages.—

James J. Stone, Onondaga Health Association.

Then a statistician comments on the above:

I am very much interested in Mr. Stone's proposal. It seems to me the project would be both useful and practicable.

There are several *variables* involved in the problem, of which the important ones are:

a—the medium

b—the quality of the material

c—the sample of persons exposed to the material

To conduct the experiment ideally, it would be necessary to vary the medium used while holding the other two variables constant, but it is obviously impossible to use the same material a second time on the same group of people. Accordingly, the sample would have to be changed, but it would be desirable to have a sample as closely similar as possible for each repetition of the experiment. The samples should be similar both with respect to the kind of people included and in respect to their preparation for the test. I wonder if, even though the attempt to avoid newspaper discussion of the experiment were successful, repetition of the experiment in the same city would not find a second sample of people somewhat affected by the first experiment.

I think the best method of making this test might be to try out each of the media considered (car cards, posters, radio and newspapers) in different but similar communities simultaneously. It would be possible to select four samples of 1,000 people in similar communities which would probably be as nearly alike as four samples selected successively in one community, and this plan would permit the use of the same material with each of the four media, or at least much more nearly the same material than would be possible if the experiment were repeated four times in the same community.

There would be considerable expense in making the experiment even once; \$40 for postage, for example, in using a sample of 1,000 people, to say nothing of other expenses. The study seems to me to have possibilities

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

and I think it might be worth the extra expense involved in making it in four places rather than in Syracuse alone.—

Ralph G. Hurlin, Russell Sage Foundation.

We Cannot Make It Too Simple

—By writing one's name and address on a slip of paper (or business card) and adding a designated number, a copy of one of a number of valuable publications will be supplied free to any one who visits Education-Publicity Headquarters at an Annual Meeting. But at Chicago 20 persons turned in slips with no number to indicate what was wanted—and the editor is not a mind reader.

Since the address slips or cards are sent to the respective publishers it is especially important that but a single number be placed on a single card. But it took more than half a day from other work to copy the addresses of people who failed to observe this request at Chicago. And neither mailing clerks nor postal clerks could read some of the addresses given.

Twice recently when we used some of this free material in meetings it was explained that always some people fail to hear the instructions—and in both those meetings several people failed to hear what was explained in detail. We cannot be too careful in giving instructions or information to be used by other people.

What Do You Want?—Really and truly what kind of information and other material would you like to have appear in this department? more about appeal letters and printed matter used in connection with money raising? more definite suggestions and examples in the preparation of health education folders? or are you most concerned with newspaper articles?—and so on—what do you really wish?

Are the school health workers reading this department for more references

to printed matter, ideas and discussions of classroom activities?

Is there any one who makes any use of the "Titles," or "Slogans and Phrases"?

If you do not find what you most want in this department, please tell the editor, for it is quite possible your wishes can be met if they are made known.

If what does appear in the department is of little interest or use to you, please say so. It will not take many objectors to relieve the pages of the excess baggage.

But it is up to you.

In the Other Half of the World—

The statement in the paragraphs below are so familiar that they are worth quoting only as an illustration of how similar the health education methods are in this distant part of the world to those here. One difference is that the English use the word propaganda to mean propaganda, while here we use it to mean bad propaganda.

Many of the leading provincial and local newspapers gave due publicity to the reports of Baby and Health Weeks Celebration held at different places. A series of four articles . . . were published in practically all the English and vernacular newspapers in July and August last. The articles sought to prove by laying emphasis with the help of statistical information on the great part played by many preventable diseases in intensifying poverty; the causes of these diseases and the methods of their prevention were then explained in brief. . . .

The proceedings of the Public Health, Maternity and Infant Welfare Conference and the Exhibition arranged by the Association in August last in Poona, India, were given wide publicity in the press. In November last a public appeal for funds was issued to the press, giving a brief interim report of the work of the association, mentioning the various ways in which the association offers material assistance in the celebration of Mofussil Baby and Health Weeks. This appeal also appeared in many provincial and local vernacular papers. Lady Cowasji Jehangir (Junior) arranged a series of six talks on Infant Welfare to be broadcast from the studio of the Indian

Broadcasting Company and Lady Cowasji herself and Dr. Tilak broadcast two talks in the series in December last.—

Report of the Bombay Presidency Baby and Health Week Association, 1927.

A Meeting That Did Not "Just Grow"—The steps taken in planning the meeting at Chicago to discuss "Steps in Planning a Year-Round Program of Health Education" illustrate the procedure followed in the careful preparation of one type of program.

Mrs. Routzahn and Dr. Galdston were a committee of two to arrange the meeting and, in consultation with other members of the Section Council, they selected topics and speakers. The participants accepted their assignments from three to five months in advance of the meeting. Each received an explanation of the purposes of the program and of his own part in it.

Abstracts or complete papers were sent to the chairman a month before the convention. These were duplicated and sent to each speaker, together with comments and suggested changes, to avoid overlapping and to fill in some of the gaps. Several papers were considerably revised as a result of this exchange between speakers. The psychologist, who was unfamiliar with the field of health education, received a collection of health booklets and folders and a brief account of the interests of the persons likely to make up the audience.

This is a simplified account of the steps taken. Some of the speakers were interviewed and numerous letters passed between the speakers and the chairmen, and much conference and correspondence preceded the selection of the speakers.

The examples of actual education-publicity programs which were discussed critically at the meeting were obtained by inviting readers of this department of the JOURNAL to submit programs which answered a list of questions about objectives, audiences, subject matter,

method of approach, choice of methods and time schedule. Mimeographed copies of this request were mailed to about 100 health workers. Many of these carried a pencilled note from the chairman which probably helped in securing attention for the impersonal form letter. About 40 replies were received, including 22 programs which were used. Of these, 14 were displayed at the headquarters of the Section, and 8 were used for discussion. All of the 8 selected generously responded to a request that they supply 500 mimeographed copies. These copies were sent direct to the convention headquarters and were assembled there in sets and placed in envelopes by volunteers for distribution at Education-Publicity Headquarters and at the meetings.

Window and Other Exhibits—A memorandum on window exhibits prepared by the editor of this department applies largely to fair and exposition exhibits. Here is the memorandum as distributed by the Philadelphia Welfare Federation:

Subject matter of a window exhibit: Something that is important to tell the public *which can also be made interesting and intelligible in graphic form.*

A live or moving display must *usually* be one which can be put on all through the business day—and the evening as well.

Whatever else you do, be interesting—don't risk being dull or stupid.

The display must appeal to the "general public," not to the staff, board members or the friends of those who plan the display.

Crude or rough forms can be used only if done artistically—home made exhibits must not look "home made."

All placards should be worked out most carefully—as to wording—capitalization and punctuation—kind of letter—size and spacing of letters—color of card and lettering—position in

window and manner of display—if on floor to have stiff backing and solid easel to hold to correct angle without being leaned against something—being sure that every word can be read easily and quickly from the outer edge of sidewalk.

Be very, very sure to study windows—and your window—so that you may think in terms of actual conditions—and not merely of so many feet one way and so many another with a sheet of glass in front.

In a *good window*: simplicity; unity; unusual appearance.

In a *bad window*: small pictures; small lettering; too little space—between lines—between letters; too low.

To *dodge attention and interest*: Crowding—too many objects—too many words—too many ideas—too close together; messiness—too many different shapes—and materials and pieces; crudity—in workmanship—dolls not life-like—bad art—flimsy looking structures—looks too “home made”; tapes or ribbons—confusing and distracting; detailed maps—except on a quiet street for unhurried passerby; lists; groups of photographs.

To *get attention*: striking color; movement; large size; three dimensions; an idea related to interests of the passerby (the man on the street); an idea that can be quickly grasped; a treatment which does not seem trivial and casual; use of the human figure as well as of things.

Among the possibilities in materials and other features to use are the following:

Backgrounds—novelty papers; crepe papers; draped materials—usually plain vertical; painted background; wall paper; scenic effect—street—skyline—camp surroundings; row of large silhouetted figures; large scale outline

sketches; large blackboard (extended horizontally)—may have imitation of school blackboard decorations.

Mechanical devices—automatic stereopticon; automatic picture display; continuous motion picture; open book with turning pages; moving belts; colored lights; opening and closing doors; revolving platform; moving figures.

Objects—massed quantities—as soap or bread used in one year—or figures in swimming suits to show how many have learned to swim; hand work (be sure to bring out its significance); equipment for hospital, playground, etc. (mildly interesting); models (if buildings—add cutouts of people to give life).

Dramatic forms—tableaux; marionettes or puppets; demonstrations; pantomime; interpreters—to point to objects and placards—to place placards—to write on blackboard.

Physical forms—cutout photos; cutout silhouettes; outline sketches; enlarged cartoons; *much* enlarged photographs; any of above as transparencies; heavily mounted and cutout letters; outline maps—with great discretion; picture maps—ditto; posters—more so; “little theatre” form—be sure to have action in scene staged; diagrams—rows of silhouettes—rows of objects—flashing lights—heavily mounted cutouts—strips of wood or colored paper—tall cylinders (possibly with cutout silhouettes or photographs on the front).

Helps and helpers: Make a “census of useful people”; get an artist as adviser on color and general effect; a good amateur photographer may work out silhouettes; a manual training teacher may handle cutouts; an official in a factory may get interested in working out a moving device and may provide motor for same; groups of women may cut out pictures not mounted on wood.

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

Pass the Parker Bill—A vigorous resolution urging Congress to pass the Parker Bill for federal health coordination over the veto of the President was adopted by the Association at its 57th Annual Meeting in Chicago in October, 1928. The second session of the Seventieth Congress convenes December 3, 1928, and will adjourn March 3, 1929. The time for action is short, but there is time enough for this desirable procedure.

The principles of the Parker Bill have been indorsed by the American Public Health Association every year since 1925, and Congress finally adopted the measure, somewhat amended, in May, 1928. Apparently due to the influence of General H. M. Lord, Director of the Budget, President Coolidge vetoed the bill on May 18, giving as reasons the fact that one section was considered unconstitutional and that the bill tended to "militarize" the U. S. Public Health Service.

The palpable fallacies of these arguments have already been discussed in this department. Though the Parker Bill by the amendments lost a certain effectiveness, it is still a very important measure, especially in its provisions for allowing the detail of U. S. Public Health Service personnel to other government bureaus; in granting a commissioned status to sanitary engineers and other scientific personnel of the service; in providing for a Nurse Corps; and in setting up a national advisory health council.

Sanitarians are still interested in this excellent measure and keenly desirous that it be passed now. If it is not, the bill must be reintroduced and passed all

over again in the next Congress. It would be helpful if sanitarians would communicate with their United States Senators and Representatives regarding this important matter. Do it now.

Traveling Expenses and Income Taxes—At last the somewhat muddled matter of travel expenses and federal income taxes of physicians seems to be getting more or less settled. On October 2, 1928, the U. S. Board of Tax Appeals ruled in *Jack v. Commissioner of Internal Revenue* that the amounts expended by a physician for railroad fare, hotel accommodations and meals in connection with attending meetings and conventions of various medical associations could be deducted as ordinary and necessary expenses in computing income tax returns.

This decision does not become final until 6 months after its promulgation, during which time the Commissioner may appeal to the courts if he so desires. It is to be hoped that he will not, for this decision and a previous one, *A. Silverman*, 6 B.T.A. 1528, in which a chemist was allowed to deduct traveling expenses in attending a professional society meeting, would seem to be sufficient precedent for authorizing members of the American Public Health Association who pay their own expenses to professional meetings to deduct such expenses in figuring their income taxes, if they are affluent enough to have any.

Applications for refunds for previous years, a separate application for each year, may be filed now with the Commissioner of Internal Revenue, using *Form 843*, and showing thereon that the application is based on *Jack v. Commis-*

sioner of Internal Revenue, Docket Nos. 14995 and 17662. The *Journal of the American Medical Association* in an editorial on this matter in its issue of October 27, 1928, estimates that the medical profession has paid as much as half a million dollars into the federal treasury for these taxes since 1922, when the Commissioner first denied the deductions. This *Journal* is, as usual, somewhat sarcastic about it, and properly so in this case.

More Liability for Typhoid—Still another court decision sustaining an award of damages for typhoid fever caused by impure water has joined the number of cases which have been discussed recently in this department. Municipal and private corporations ought by now to be cognizant of the fact that it does not pay to be careless in supplying water to the people. Water companies seem to be paying dearly for the knowledge that they owe a duty to the public to exercise reasonable care to see that water furnished for human consumption is pure, potable, and free from contamination.

The latest decision comes from California and represents an opinion in 19 cases brought against a city for deaths and illnesses due to a polluted municipal water supply, *Ritterbusch v. City of Pittsburg*, 269 Pac. 930. The facts were that a chlorination plant used to treat the city water became inoperative for 12 hours in June, 1920, and unchlorinated water was supplied to the city. The result was an epidemic of typhoid and dysentery.

The California Supreme Court upheld judgments against the city awarded by lower courts on the ground that the evidence was sufficiently conclusive to show that the epidemic was due to the negligence of the city in failing to treat the water properly. Once more public health is advanced by the courts. Other court decisions on this same subject

have been collected and discussed by the Associate Editor, who will send a reprint on the subject to anyone who wants it.

A BIBLIOGRAPHY OF PUBLIC HEALTH LAW

For the benefit of sanitarians there is presented herewith a list of references to the more important articles, bulletins, and books on various phases of public health law which have appeared during the past 2 years. All significant material which was published prior to that time is cited in the book *Public Health Law*.

VITAL STATISTICS

Fales, W. T., Kopf, E. W., and Tobey, J. A. Constitutional, Statutory, and Administrative Aspects of Vital Statistics, *A. J. P. H.*, Aug., 1927.

We Bow Ourselves Out—With this issue the writer has completed 9 years' service as editorial assistant and associate editor of the *AMERICAN JOURNAL OF PUBLIC HEALTH*. His tenure of office has been longer than that of any other member of the present Editorial Board, except Dr. E. R. Hayhurst.

Due to increasing demands on his time, lack of sympathy with the policies of the present chairman of the Editorial Board, and other reasons, the writer regrets to state that he considers it desirable to relinquish the pleasant, if somewhat arduous, duty of conducting

this monthly department on Law and Legislation.

Although the *JOURNAL* carried an anonymously conducted section on "Legal Decisions" in 1916, the first systematic attempt to present reports on public health legislation was inaugurated in 1920, when the writer's material assembled for the National Health Council was incorporated regularly in the *JOURNAL*. In March, 1923, this legislative material was placed in a separate department, which has been continued up to now, though with increasing and broadening scope. In recognition of this advance, the name of the department was changed to Law and Legislation in 1925.

During his 9 years of service the writer has contributed about 250,000 words to the *JOURNAL*, chiefly in his own department, though occasionally in news items and editorials.

That the material on Law and Legislation has been profitable not only to the writer but also to the readers seems indicated by the numerous communications which have been received commenting on various items or requesting information on legal topics. Only once during the entire period has anyone taken issue with anything that has been said in this department, though no doubt there have been plenty of provocative statements, all of which, however, the writer has been willing and able to support.

The legal side of public health is one of the most important subjects which confront the health official. For his own protection, as well as for his efficiency as an administrator, he should have an adequate working knowledge of public health law. It has been the writer's privilege to contribute something to that knowledge in the past through this department and in other ways, and he expects to continue his interest in that subject.

BOOKS AND REPORTS

A Short History of Medicine, Introducing Medical Principles to Students and Non-Medical Readers—By Charles Singer, M.D., D.Litt. Oxford. New York: Oxford University Press, 1928. 368 pp. Price, \$3.00.

The name of the author and the press from which this book comes are sufficient to assure one of its quality. Examination of the contents further convinces the critic that his confidence has not been misplaced.

Dr. Singer assumes that medical science has now reached such a stage that some knowledge of it is demanded of all educated men and women whether or not they have had medical training. He supports the historical method of teaching.

The outstanding aim of the work is to lay stress on the principles of medicine rather than the details of practice; to treat medicine as a science rather than to give the histories of individuals, though this feature has not been neglected. The term "philosophy" is frequently substituted for "principles," and this term is explained in the preface as standing for the "disinterested study of the theory of the subject, without reference to its application to particular instances."

Beginning with an illuminating picture of Greek medicine, in which our debt to those early times is shown, we are carried as rapidly as possible through the schools described as "The Heirs of Greece," those of the Middle Ages down to modern medicine, to which more than half of the book is devoted, the writer presenting it "as a natural outgrowth of an ancient tradition."

The author dates the beginning of modern medicine, which he calls the

"Period of Scientific Subdivision," at about 1825. After a brief discussion of the causes for this scientific specialization, he begins with the study of preventive medicine in England and in this country, and in sequence considers those lines of thought which have brought medicine to its present state. We find the history of the cellular theory of pathology, the germ theory of disease, anesthesia, advances in surgery, bacteriology as a special science, immunity, psychology, nursing, physiology, and studies of the special senses discussed.

In view of the author's object—to teach students and non-medical persons the history of the science of medicine—he has given his account in language as simple as possible so as to make the smallest demand upon the scientific equipment of his readers. He has, however, avoided the very common mistake made by writers of more or less popular books of taking as his target the mental age of about ten.

It is unusual to find a book designed for such a wide range of readers so well balanced. Not only can the historian, but the average medical man, as well as the layman, find here the knowledge which he seeks, presented in clear language and orderly sequence.

The book closes with an epilogue which is somewhat philosophical in character, though its application is practical. The debt which medicine owes to the various sciences is emphasized, and we are urged to encourage the study of science as a whole, or of learning as a whole, rather than to make a "direct attack" on medicine, which has been one of the mistakes of the past. It is pointed out that medicine "cannot give immortality, but it should enable us

all to live out our full lives. Death, coming in due and not undue time, is shorn of all his terrors, when every man and every woman

Shall come to his grave in a full age,
Like as a shock of corn cometh in, in his season."

The printing and make-up of the book are excellent, and there are many unusually good illustrations.

M. P. RAVENEL

The Glands Regulating Personality
—By *Louis Berman, M.D.* (2d. ed. rev.) *New York: Macmillan, 1928.*
341 pp. Price, \$3.50.

There is no doubt that one of the most interesting as well as important problems before the physiologist and practitioner is that of the secretions of the ductless glands and their effect upon the body and its functions.

The author of the present book conceives that every person is dominated by his internal secretions, and he uses the terms "pituito-centric," "thymo-centric," "gonado-centric," "pituito-adrenal," etc., to designate persons who are chiefly influenced by one gland or combination of glands, giving descriptions of the types which may be expected from the action of one gland or the other. In order to prove his case, he analyzes the characters of a number of historic personages such as Napoleon, Nietzsche, Darwin, Caesar, Oscar Wilde and others, whose peculiarities as well as genius are attributed to the particular internal secretions which dominated them. Finally, there are chapters on Applications and Possibilities, and Evolution, in which he goes so far as to indicate that endocrine hygiene may control crime and improve the race, since "A man's chief gift to his children is his internal secretion composition."

The author is evidently widely read, and he interweaves facts with his fantastic theories so skilfully as almost to deceive the elect. This book may serve to amuse those who are well posted on

the subject of endocrinology. We believe it to be distinctly dangerous and misleading to anyone who has not a sound fundamental education. As an example, we know that the first edition was ordered by the School of Education of a certain university—not by those in the Medical School, who would not have been misled.

Needless to say it contains a great deal that is true; but this is so interwoven with theory and imagination that one must sound a note of warning concerning its fallacies. M. P. RAVENEL

Nurses, Patients and Pocketbooks—
A report of the Committee on the Grading of Nursing Schools—
By *May Ayres Burgess.* *New York: Committee on the Grading of Nursing Schools, 1928.* 618 pp. Price, \$2.00.

This valuable study presents the results of a comprehensive survey of the nursing profession. The first part presents the facts brought out by the research, while the second discusses their implications. Some of the chapter headings, indicating the general nature of the facts gathered, are:

Is there unemployment now?
What registrars say.
Is there a public health nurse shortage?
Are physicians satisfied?
Are patients satisfied?
How do nurses like their jobs?

Perhaps the outstanding conclusion of the committee relates to the supply of nurses, for statistics indicate that there is a decided over-production. If present trends continue, this over-production will produce a serious situation. Other general facts ascertained are: there is no dearth of applicants for public health nursing positions, but there are not sufficient applications by well-qualified candidates; physicians prefer registered to practical nurses, but cannot always get the type of nurse desired for unpopular varieties of cases; the incomes of most private duty nurses are

low, half earning \$1,297 or less a year; the competition of "practicals" seriously affects the incomes of R.N.'s; the quality of many R.N.'s is distinctly below that required by physicians and the public; practical nurses seem as popular with patients as R.N.'s, but this is not the case with physicians.

The report indicates a most unsatisfactory state of affairs among nurses, especially those not in institutional or public health work. Of those in private duty, 55 per cent plan to remain in the field, while among public health and institutional nurses the corresponding figures are 86 per cent and 82 per cent. Part of this discontent arises from the long hours in private duty. Over 56 per cent of home nursing days are on the 24-hour basis, while in hospital service the corresponding figure is only 12 per cent. The pay is low, does not vary with ability and experience, and there is no future to private nursing. The typical private duty nurse gives about 1 month out of 12 to free service.

In its discussion of the implications of the facts ascertained the committee makes several useful suggestions, while at some places it admits it has no immediate solution to offer.

The investigation has been thorough, the conclusions being based upon 34,000 returns from nurses, 28,000 from physicians, 3,400 from hospitals, and 3,200 from patients, registrars, etc. The book is easy to read and easier to remember because of the summary at the end of each chapter. The liberal use of good diagrams also aids the presentation. The practice of giving excerpts from letters of physicians, nurses and patients has helped in giving an adequate picture of the situation, as well as making the volume more readable.

This committee is composed of 21 members representing nurses, doctors and the public, and is sponsored by the American Medical Association,

the American College of Surgeons, the American Hospital Association, the American Nurses' Association, the National League of Nursing Education, the National Organization for Public Health Nursing, and the American Public Health Association. Its ultimate purpose is "the study of ways and means for insuring an ample supply of nursing service, of whatever type and quality is needed for adequate care of the patient, at a price within his reach." To accomplish this, a 5-year program of research has been outlined of which this volume covers the first project. The other two studies, which will be looked forward to with undoubted interest because of the high quality of this first report, will be "What nurses need to know and how they may be taught" and "The grading of schools of nursing."

ALLAN PEEBLES

A Manual of Tuberculosis Legislation—By James A. Tobey, LL.B., Dr.P.H. New York: National Tuberculosis Association, 1928. 86 pp. Price, \$.50.

This manual is the eighth of a series of technical publications issued by the National Tuberculosis Association.

In Part I of the manual, the underlying principles of tuberculosis legislation are discussed. This is followed by an outline for a state legislative program against tuberculosis, with practical hints on law making. Part II consists essentially of an analysis of existing state and county tuberculosis legislation, arranged according to subject matter. It includes a consideration of general public health administration, reporting and legislation, control of cases and contact, establishment and maintenance of sanatoria, and miscellaneous measures. Part III supplies an index to tuberculosis legislation by states, arranged in alphabetical order, and a chronology of important legislation from 1893, when Michigan required reporting by a regu-

lation of the State Board of Health, to 1909, when New York and Ohio each passed county sanatorium laws, the first in the United States.

The information is complete but concise, and so well arranged that the book serves as a ready reference on any topic concerning tuberculosis control by legal or legislative means.

H. E. KLEINSCHMIDT

Directory of Psychiatric Clinics for Children in the United States.
New York: Commonwealth Fund Division of Publications. 187 pp. Price, \$.75.

This Directory presents the results of a recent survey of clinical facilities for child guidance throughout the United States, made by the Division on Community Clinics of the National Committee for Mental Hygiene. Under each state is given a list of local clinics providing regular service for the study and treatment of conduct problems, the number of children handled in each clinic during the past year, and a description of the institutions and community resources in mental hygiene under state governmental auspices, as well as the names, addresses, and chief activities of state and local mental hygiene societies.

How You Can Keep Happy—By William S. Sadler, M.D., F.A.C.S.
Chicago: American Health Book Concern, 1926. 292 pp. Price, \$3.00.

The basis of this book is the conviction, which the author seems to claim as his own, that happiness in living is largely a question of emotional control. If we succeed in having certain emo-

tions and sentiments dominate us, our life is joyful, while, on the other hand, allowing our more primitive and less desirable emotions to control us brings sorrow, fear and unhappiness. The most interesting part of the book is Part IV dealing with the methods of emotional control.

There is nothing new in the book, but the material is interestingly presented, and will doubtless be of aid to certain types of people who have not cultivated self-control and to those who desire to do so. M. P. RAVENEL

Recent Advances in Chemistry in Relation to Medical Practice—By W. McKim Marriott. St. Louis: Mosby, 1928. 141 pp. Price, \$2.50.

This small volume is a reprint of the six lectures given by the author at the San Diego Academy of Medicine in 1926. The lectures were given to show the application of some of the fundamental principles of chemistry to the practice of medicine and its extensive development in recent years.

In the first chapter of the book, brief discussions are given of such fundamentals as the structure of atoms and molecules, ionization, hydrogen ions and their values, surface tension, osmotic pressure and colloids. In the remaining chapters these principles are applied to acidosis and alkalosis, the chemistry of the blood, foods and metabolism and the endocrines and their clinical application.

This little book will be especially valuable to medical graduates of a few years ago by whom recent chemical literature may not be easily understood.

A. B. HAW

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Providence, R. I.—The forty-fifth annual report of Providence for 1927 records a population of 272,400, a birth rate of 11.6, and a marriage rate of 16.3 per 1,000 population. As in previous years, a classified financial statement compares the expenditures in 1926 with those in 1927, the latter amounting to \$205,182 (\$127,158 garbage removal contract). An appraisal of all health activities in the city, on the A. P. H. A. Appraisal Form, gives a rating of 851.6 as compared with 816.8 for 1926. The principal increases are noted under activities of child hygiene, including prenatal, preschool, and school, and under communicable disease control, especially immunization.

The first step in the supervision of the health of infants is the distribution of prenatal letters to prospective mothers each month. In 1927 there were 1,068 requests for such letters as compared with 897 in 1926. Five nurses supervise, until they are 3 years old, the children delivered by midwives (10.8 per cent of total live births), making each well baby ten calls before it is 1 year of age, and as many other calls as are necessary if the child becomes sick. One nurse supervises the infants and young children in licensed boarding homes, and the infants of such unmarried mothers as are not under the supervision of private agencies. One nurse from the department makes one visit upon each infant delivered by a physician, provided the mother is not on the maternity service of the Providence District Nursing Association or delivered at the Lying-in Hospital. An infant mortality rate of 63 for 1927 is recorded.

Three important changes were made during the year in the methods of garbage collection and disposal: (1)

transfer of the control and management from the health department to the Commissioner of Public Works; (2) arrangement for collection and disposal by the municipality rather than by contract; and (3) adoption of incineration rather than feeding to swine. "In Providence, as in all other cities in former years, garbage disposal was considered an important health problem, and although it is now known to have practically nothing to do with health, the force of tradition has kept it in this department."

Worcester, Mass.—The 1927 Massachusetts legislature passed an act establishing a standard for ice cream and regulating its manufacture and sale. "All such places (in Worcester), when it was proposed to manufacture ice cream, have thus far been thoroughly inspected by the entire board." New regulations were adopted during the year concerning the handling of milk, pasteurization, and the care of plants and utensils.

A birth rate of 23.3, a general death rate of 13.1, and an infant mortality rate of 57 are reported for 1927. Several good statistical charts are features of the report.

New Britain, Conn.—The annual report for the year ending March 31, 1928, opens with a concise statement of the different functions of the department. An annual expenditure of 79½ cents per capita is noted for this city of about 70,000. An infant mortality rate of 71.2 is recorded, with a general death rate of 8.2. There were 32 diphtheria cases reported with 1 death, and 102 tuberculosis cases reported with 40 deaths. It is reported that this city, together with several surrounding towns,

is on the state and federal accredited list, "which means that all bovine animals within those areas are regularly tuberculin tested at state expense."

Illinois—The annual report for the year ending June 30, 1927, describes the work of the department of public health for the 50th year since the law creating the first state health service in Illinois became effective. A history has been prepared which covers this 50-year period. It is stated that the most noticeable change in conditions is the fact that whereas the summer season was formerly more unhealthful, as indicated by mortality statistics, now the winter and spring months are less favorable. Sickness and mortality now fall to a minimum during August and September, whereas February, March, and April make up the quarter when illness and mortality reach maximum levels. Decreases in diseases such as typhoid, malaria, dysentery and diarrhea, are largely responsible for this change. In 1926, typhoid and diphtheria prevalence reached the lowest points recorded in the history of the state.

This report contains accounts of divisional activities, with several good charts and excellent photographs. In the child hygiene and public health nursing section, it is learned that the department of public health and child welfare of the Illinois Federation of Women's Clubs decided to sponsor a preschool child health program for a period of 5 years. Each club woman agreed to be responsible for the examination of one child each year, this being done by the family physician and family dentist in their own offices. The program was outlined and standardized by a committee made up of representatives of the state medical and dental societies, the Federation of Women's Clubs, and the Division of Child Hygiene of the state. During the year, a preschool examination card was pre-

pared, and more than 40,000 of them were requested for use by various groups, while members of the division assisted with the examination of more than 7,000 preschool children.

In coöperation with a plan accepted by the presidents of the five state teachers colleges for a course in health education for students in teacher training institutions, and in order to impress the prospective teacher with the value of a complete physical examination as the basis for health education, to collect information regarding health conditions of the future teachers, the State Department of Public Health offered the services of a physician (coöperating with the local medical and dental profession) as a demonstration measure. Over 1,400 students were subsequently given physical examinations at three of the five state teachers colleges.

White Plains, N. Y.—Printed in good readable type, on soft paper, with excellent statistical tables and graphs and a few photographs, the 1927 health department report of White Plains is a credit to this city of 29,888 people. Scored on the Appraisal Form of the A. P. H. A. by the health officer, a rating of 865 out of a possible 1,000 points is obtained. This rating includes the health practices of all agencies participating in the community health program. A birth rate of 20.8, a general death rate of 9.6, and an infant mortality rate of 49 are recorded.

Increased laboratory examinations are noted during the year. These include Wassermann tests, Widal tests, and examinations of water, milk, and ice cream, as well as of other routine specimens. The work in child hygiene and tuberculosis clinics has expanded, weekly clinics having been held under the direction of a local physician. Department nurses made 2,977 home visits for the purpose of seeing babies and prenatal cases, of following up cases of

tuberculosis and venereal diseases and of interesting patients in regular attendance. Little Mothers' Leagues and Junior Health Leagues have been organized in schools.

Expenditures for health work by the Department of Education amounted to 56 cents per capita, by the Nursing Association to 84 cents per capita, while the amount spent for the care of cases of contagious disease, acute venereal disease, tuberculosis and psychopathic cases was \$1.76 per capita. "If the amounts spent by the various organizations mentioned above are added to the amount of the health department budget, the total amount spent for health activities in White Plains during 1927 was \$4.11 per capita."

Baltimore, Md.—Baltimore had an estimated population in 1927 of 819,012, of whom 121,296 were colored. Birth rates of 18.5 for the white population and 27.7 for the colored population, with death rates of 12.3 and 24.4 respectively, were recorded. Detailed statistical tables in the last report include data regarding population and deaths beginning with 1875. For the current year, deaths are analyzed by age, sex, month and cause, while births are classified by nativity. The infant mortality rate of 81.6, 69.9 for whites and 127.0 for colored persons, is lower than for previous years.

Tables are presented to show that 58,323 children have been immunized by toxin-antitoxin, 1922-1927, of whom 16,430 were pupils entering school, and 9,173 were preschool children. Other data include a compilation of questionnaires sent to physicians who used scarlet fever serum, the general tone of the responses being favorable as regards treatment results.

Regulations governing the manufacture of ice cream require that cream be produced from milk which is of the same grade and quality as that milk

which is used in the regular bottle trade. In the milk division, also, measures were enforced for proper cleansing of milk bottles, followed by steaming or chlorination.

This report of 256 pages contains a table of contents at the front, and an alphabetical index at the back. A classified financial statement shows expenditures amounting to \$790,434 during 1927. The report is printed in good readable type, and is bound in attractive soft blue paper covers, with a well-arranged title page.

East Orange, N. J.—During 1927, 74 per cent of the 1,308 births in this city of 66,640 population occurred in hospitals, while 32 per cent of the 658 deaths occurred in hospitals. Births and deaths are analyzed by wards and nationality, and the latter are also classified by cause in accordance with the International List. The fly leaf of the report carries a diagrammatic sketch of the comparative ratings of the city activities based on the Appraisal Form, 836 having been obtained in 1925 and 900 in 1927. The last three pages of the report are devoted to a statement of the finance committee, which includes a detailed classification of expenditures. The appropriation for 1927 was \$43,836.

Fully 80 per cent of the school children have been protected against diphtheria and an increasing number of preschool children are being so protected by the family physician. There were 42 cases of diphtheria with no deaths, 33 of the cases occurring in children under 10 years of age who had not been immunized. During the year, 186 persons were bitten by vicious dogs, and 7 dogs were found to have rabies. The Board of Health has recommended that a city ordinance be passed requiring vaccination against rabies as a prerequisite to licensing of dogs, but no action along this line has resulted.

The report is written in accordance with the outline of the Appraisal Form and contains an immense amount of interesting data for health officers of cities of this size. There are many good statistical tables and graphs with appropriate descriptive text.

Scotland—The population of Scotland in 1927 was 4,894,700, and the general death rate was 13.5 per 1,000, while the death rate from tuberculosis was 99 per 100,000, and the infant mortality rate was 99 per 1,000 births. Since 1890, local authorities have had power to provide houses for the working classes, although this was little used until 1919. During 1927, the total number of working class houses erected was 21,660. As it is estimated that 10,000 are required annually to meet normal requirements, there is now believed to be a substantial number of houses to set against the great shortage,

estimated by the Royal Commission in 1917 to amount to 121,430 houses.

Another feature of the year, according to the ninth annual report of the Scottish Board of Health, was the launching of a scheme of contributory old age pensions, which, together with contributory pensions for widows and orphans initiated in 1926, completed the system of contributory pensions—now reaching more than 150,000 persons.

There were two major outbreaks of infection during the year, one a widespread epidemic of influenza, and the other of smallpox. The latter disease, involving 155 cases, was of a mild type, resembling the type found in recent years in England. The principal causes of death in order of magnitude during the year were as follows: heart disease, "malignant disease," apoplexy, pneumonia, bronchitis, diseases of early infancy, tuberculosis, influenza, nephritis and diarrhea and enteritis.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Fumigation with Cyanogen—A report of experiments conducted with cyanogen products used in fumigating vessels at quarantine. A proprietary product of liquid HCN is found satisfactory.

AKIN, C. V. Fumigation with Cyanogen Products. Pub. H. Rep., 43, 41: 2647 (Oct. 12), 1928.

Bacterial Counts in Milk—A demonstration of the errors in the methods used to demonstrate the inaccuracy of milk plating. With proper care consistent plate counts of milk can be made.

ALBUS, W. R. Some Observations on the Plate-Count Method of Enumerating Bacteria in Milk. J. Bact., 16, 4: 269 (Oct.), 1928.

Massachusetts Cancer Campaign—An account of the state-wide cancer campaign and the results in increased attendance upon private practitioners and public clinics for diagnosis and help which resulted.

BALCH, F. G., *et al.* Results of the Massachusetts Cancer Campaign. New England J. M., 199, 9: 430 (Aug. 30), 1928.

Swimming Pool Sanitation—A study of swimming pool sanitation in Great Britain leads the author to conclude that safe conditions can be maintained only by keeping the residual chlorine content at from 0.2 to 0.5 part per million.

BOWES, G. K. The Bacterial Examination of Water in Public Swimming Baths. J. State Med., 34, 9: 521 (Sept.), 1928.

Value of Health Examinations—The author presents a distorted picture of the periodic health examination and its result upon one unbalanced patient. He concludes by devious reasoning that

the evidence for the health audit "has the same general character as that submitted to Ponce de Leon." The paper is typical of the magazine in which it appears and the harm that it will do is therefore problematic.

CLENDENING, L. Health Audits. Am. Mercury, 15, 58: 145 (Oct.), 1928.

Influences in Life Conservation—Both the practicing physician and the sanitarian have indispensable parts in saving lives; the interrelationships and mutual dependence, one on the other, are arrestingly presented.

CALVER, H. N. Retail or Wholesale Life Saving: Which Pays Best? J. A. M. A., 91, 17: 1284 (Oct. 27), 1928.

Recording Children's Development—A description of a method of photographing the front and lateral views of children for a stereoscopic record, affording an excellent means of visual comparison.

CLOUGH, H. D., and MURLIN, H. D. Permanent Records of Growth and Nutrition of Children. Am. J. Dis. Child., 36, 3: 425 (Sept.), 1928.

The Tuberculosis Problem—A British symposium on tuberculosis preventive measures emphasizing the failures as well as the successes of the anti-tuberculosis movement.

COUTTS, F. J. H., *et al.* The Present Position of the Tuberculosis Problem. J. Roy. San. Inst., 49, 3: 65 (Sept.), 1928.

Deafened Children—A second report on tests of children's hearing by means of an audiometer. Annual tests of the school child's hearing are again urged.

FOWLER, E. P., and FLETCHER, H. Three Million Deafened School Children. J. A. M. A., 91, 16: 1181 (Oct. 20), 1928.

Infant Diet Self-Selection—A very interesting record of allowing the self-selection of a wide variety of food-stuffs by newly weaned infants. Should be read by all who are concerned with the care of infants; so interestingly told that all will enjoy reading it.

DAVIS, C. M. *Self-Selection of Diet by Newly Weaned Infants.* *Am. J. Dis. Child.*, 36, 4: 653 (Oct.), 1928.

Tularemia—A timely paper on the symptoms, diagnosis, pathology and prevention of tularemia. The wearing of rubber gloves by those who hunt or cook rabbits occasionally is sufficient, but for others who handle rabbits frequently some protective treatment is needed.

FRANCIS, E. *Symptoms, Diagnosis and Pathology of Tularemia.* *J. A. M. A.*, 91, 16: 1155 (Oct. 20), 1928.

Health Education Values—Arguments are presented to indicate the place of popular health instruction in furthering public health consciousness, the prevention of disease, and the promotion of effective therapeutics.

GALDSTON, I. *Tuberculosis Prevention and Health Education.* *Am. Rev. Tuberc.*, 18, 8: 264 (Sept.), 1928.

Eskimos' Susceptibility to Colds—

Whenever an outsider visits an Eskimo colony, even though he is without symptoms, an epidemic of colds is started. Adult Eskimos are invariably Schick negative though the disease is unknown and the children are usually Schick positive. All are Dick negative.

HEINBECKER, P., and IRVINE-JONES, E. I. M. *Susceptibility of Eskimos to the Common Cold and a Study of their Natural Immunity to Diphtheria, Scarlet Fever and Bacterial Filtrates.* *J. Immunol.*, 15, 5: 395 (Sept.), 1928.

Infant Mortality—Respiratory infections, not gastrointestinal, are the commonest causes of infant mortality and are not controlled effectively. The

limitations of prenatal care in controlling neonatal mortality are considered.

HERMAN, C. *Some Factors in the Infant Mortality Problem.* *New York State J. M.*, 28, 18: 1087 (Sept. 1), 1928.

Diphtheria Immunization Campaign—This is the story of the effort to induce the mothers of Schenectady to have their preschool children immunized by the family physician. A valuable record.

GILMARTIN, H. A. *The Medical Society's Share in Protecting the Children of Schenectady against Diphtheria.* *N. Y. State J. M.*, 28, 18: 1097 (Sept. 1), 1928.

British Milk Supplies—The condition of the milk supply of Leeds, England, the lack of effective control and the absence of pasteurization, will afford an interesting comparison with conditions in comparable American communities.

JERVIS, J. J. *The Milk Supply of Leeds.* *Med. Off.*, 40, 14: 147 (Oct. 6), 1928.

Measles Prevention—An historical and critical review of the bacteriological and immunological researches into the prophylaxis and therapeutics of measles.

KATO, K. *The Bacteriology and Sero-therapy of Measles.* *Am. J. Dis. Child.*, 36, 3: 526 (Sept.), 1928.

Acidophilus Products—Of 8 commercial acidophilus products only 5 bore any information on the label as to number of viable organisms per unit; of these only 3 fulfilled the claims.

KOPELOFT, N., *et al.* *Commercial Acidophilus Products.* *J. A. M. A.*, 91, 16: 1187 (Oct. 20), 1928.

Milk and Leafy Vegetables—A chapter from McCollum emphasizing the value of milk and leafy vegetables as foodstuffs supplemental to meat and cereals.

MCCOLLUM, E. V. *Importance of Milk in the Human Dietary.* *Certified Milk*, 3, 29: 3 (Sept.), 1928.

Mussel Poisoning—An account of an epidemic of food poisoning caused by mussels taken from the waters adjacent to San Francisco.

MEYER, K. F., *et al.* Mussel Poisoning. *J. Prev. Med.*, 2, 5: 365 (Sept.), 1928.

Immunization with Anatoxin—A report of successful experience in immunizing against diphtheria with anatoxin (toxin treated with formalin) in France. Its use is advocated because of the high incidence of immunity produced, because its use is freer from accidents, and it cannot sensitize the patient to serum.

RAMON, G., AND HELIE, G. I. Diphtheria Prophylaxis in France. *J. A. M. A.*, 91, 14: 1028 (Oct. 6), 1928.

Antigenic Properties of Ultraviruses—Herpes-encephalitis virus, like vaccinia and rabies, produces no complement fixing or precipitating antibodies, but does produce virulicidal antibodies.

SCHULTZ, E. W., and HOYT, J. Studies on the Antigenic Properties of the Ultraviruses. *J. Immunol.*, 15, 5: 411 (Sept.), 1928.

Decline of Communicable Diseases—A broadly philosophic discussion of the individual environmental and social factors which tend to limit the spread of infections. The importance of animal reservoirs for the spread of disease to humans is discussed, as is the lack of knowledge of the natural history of diseases. A very important paper.

SMITH, THEOBALD. The Decline of Infectious Diseases in Its Relation to Modern Medicine. *J. Prev. Med.*, 2, 5: 345 (Sept.), 1928.

Epidemiologic Principles—A rather ponderous presentation of the more obvious principles of epidemiology, which the author states cannot be found

in any one book. We suppose he refers to books in Great Britain, for the principles are set forth in the standard American textbooks.

STALLYBRASS, C. O. The Principles of Epidemiology. *J. State Med.*, 34, 9: 510 (Sept.), 1928.

Health of Negro Children—A detailed biometric study of 5,000 negro school children in Atlanta in which the heights and weights of both sexes are recorded, and other important information such as the incidence of defects. A useful document.

STERLING, E. B. Health Studies of Negro Children. *Pub. Health Rep.*, 43, 42: 2713 (Oct. 19), 1928.

Supplying Human Milk—An account of the way human milk is collected, tested, bottled, pasteurized and distributed to needy children.

TALBOT, F. B. An Organization for Supplying Human Milk. *New England J. Med.*, 199, 13: 610 (Sept. 27), 1928.

Prophylactic Measures—This is a very valuable and inclusive summary of the prophylactic and treatment agents for twenty communicable diseases.

WHITE, B. Serums and Vaccines in the Prevention and Treatment of Infectious Diseases. A Critical Review. *New England J. Med.*, 199, 11: 505 (Sept. 13), 1928.

Preventive Medicine—Public and Private—A very frank discussion which faces courageously the vexing questions which inevitably arise between the private practitioner and the extension of the non-official and official health programs.

WILLIAMS, L. R. Present Status of the Practice of Medicine. *New York State J. Med.*, 28, 17: 1027 (Sept. 1), 1928.

NEWS FROM THE FIELD

PUBLIC HEALTH IN EUROPE

A SURVEY of the development of public health programs in foreign countries has recently been given by J. H. Mason Knox, Jr., M.D., Chief of the Bureau of Child Hygiene, Maryland State Department of Health. Dr. Knox attended the International Congress for the Protection of Infancy in Paris in July. He states:

One of the most noticeable changes is the increase in public health nurses, for during the war this activity was almost unknown. Now there are 1,500 full-time public health nurses in France. Their training for the most part has been based on the training given to nurses in this country. There has also been an increase in full-time health service in France; out of 89 departments there are 52 having full-time health officers. France has organized a rather extensive child health program and appropriations have been made by the government to many private agencies such as maternity homes, day nurseries, vacation colonies and preventoria for children threatened with diphtheria.

Throughout Europe there is a growing interest in the establishment of open air schools for both underweight and normal children. In Amsterdam the American visitor finds many child health stations where the work is conducted by a physician, several nurses, a midwife and social worker. The health station refers cases needing medical attention to the family physician, or in case of economic pressure the city health department provides for the necessary treatment. Instruction in personal hygiene and the prevention of disease is given at the health stations.

About 20 years ago Denmark organized breast-feeding stations which are being maintained now in Copenhagen. Babies who are wholly or in part breast-fed are brought to these stations. At frequent intervals they are brought back for reexamination and weighing. The mothers receive instructions and are given allowances of milk for their own daily use. Bottle-fed babies are not received at these stations.

According to the Child Welfare Act passed in 1925 every parish in Denmark constitutes a child welfare district. A child welfare council in each district is responsible for the care of dependent or abused children in that section. Insurance societies providing sick benefits are popular in Denmark and provide benefits during and after childbirth.

Sweden operates its child health program in an entirely different way. The country is divided into 2,000 sanitary districts and in each there is a children's committee, composed of a local physician, minister, school teacher and selected citizens. This committee takes charge of the health of dependent and problem children.

Sweden is also doing excellent work in the control of infectious diseases. Hospitals for the care of patients with infectious diseases have been established under government control. The government is supporting 7,000 beds in the larger cities and rural districts.

In Norway there is a system of sanitary districts presided over by a sanitary council, which is headed by a medical officer, usually a practitioner. All public health activities come under control of this medical officer, including the control of epidemics, medical assistance

to the needy and care of the insane. Norway is divided into 1,000 districts and each is provided with an official midwife who gives care to mothers in childbirth.

In 1926 Norway appropriated about \$7,000,000 to the public health department, which represents nearly one-thirtieth of its entire appropriation of \$218,000,000.

AMERICAN FOUNDATION FOR MENTAL HYGIENE

THE American Foundation for Mental Hygiene has been established according to the announcement made at the 19th Annual Meeting of the National Committee on Mental Hygiene recently held in New York, N. Y.

Clifford W. Beers, secretary of the committee, outlined the purpose and scope of this new Foundation. In part Mr. Beers explained:

It is the first Foundation organized for the exclusive purpose of financing and doing work that will enable men, women and children to live happier, healthier and more efficient lives through a better understanding and management of the processes of their minds and of the controlling forces in human behavior.

Although the Foundation was started without an endowment, Mr. Beers announced that the Foundation has received \$50,000 from the estate of Mrs. John L. Kane, and another \$100,000 has been pledged on the condition that \$900,000 more is raised. The \$50,000 will be used toward defraying the expenses of the First International Congress on Mental Hygiene, scheduled for 1930.

NEW CANCER COMMITTEE

DURING the 57th Annual Meeting of the American Public Health Association in Chicago in October, 1928, a new National Cancer Committee and a Chicago Committee were organized. These committees are not committees of the A. P. H. A.

The functions of these committees

have not been definitely outlined, but preliminary organization announcements stated that "they would coördinate, if possible, and pass on some of the present methods of cancer treatment."

Actual clinical work will be performed at the Cook County Hospital and Oak Forest Sanatorium of Chicago under the direction of the proposed local committee consisting of: Frank Billings, M.D., Herman N. Bundesen, M.D., Mrs. Wilber R. Cubbins, Gilbert Fitzpatrick, M.D., Ludwig Hektoen, M.D., L. L. McArthur, M.D., Joseph L. Miller, M.D., Frank Morton, M.D., William A. Pusey, M.D., John E. Tuite, M.D., and Gideon Wells, M.D.

The proposed National Committee consists of: Dr. J. C. Bloodgood, Baltimore, Md.; R. C. Coffey, Portland, Ore.; W. B. Coley, New York, N. Y.; Leonard Freeman, Denver, Colo.; W. D. Haggard, Nashville, Tenn.; F. H. Lahey, Boston, Mass.; Otis Lamson, Seattle, Wash.; N. J. MacLean, Winnipeg, Can.; U. Maes, New Orleans, La.; Angus McLean, Detroit, Mich.; James F. Peroy, Los Angeles, Calif.; Emmett Rixford, San Francisco, Calif.; and C. L. Starr, Toronto, Can.

In making announcement of the organization of the committees C. H. Mayo, M.D., at the Chicago meeting said it would provide a central point to which would be brought all information on any aspect of cancer collected, where further investigations could be planned, and from which information could be given out.

LEE, MASS., FOLLOWS OLD PROCEDURE

DESPITE the fact that Lee, Mass., recorded 900 cases of septic sore throat with more than 40 deaths this summer due to milk from an infected cow which was distributed raw among customers, the town has not passed regulations regarding the pasteurization

of milk. However, one pasteurizing plant has been installed in the vicinity of Lee since the epidemic but there is no community law demanding that all the milk distributed and consumed by the population of Lee be pasteurized.

MICHIGAN P. H. A. CONFERENCE

THE Michigan Public Health Association will hold its annual conference with the Michigan State Department of Health in January.

TRIBUTE TO CHARLES B. BALL

IN paying tribute to Charles B. Ball, for a quarter of a century chief sanitary inspector of the Chicago Health Department, whose death occurred while he was at his desk the middle of October, the *Chicago Daily News* editorially pays tribute also to the many men and women who are devoting their efforts to public health.

It says:

The value of such men to a community is inestimable. It is their work which makes it possible for us to live in spite of the politicians. Mayors and aldermen come and go—there have been many since 1904 when Charles B. Ball came from New York to Chicago to take up his work in this city's administration—but it is the men in the continuous service of the city, men expert and trained, men who love the work they do and do it with intelligent enthusiasm and unfailing fidelity, who make life tolerable and safe for us. Take them out of the machinery of government and leave us only the elected and politically appointed heads of departments, and we would be soon in a disastrous mess.

There are others than Charles B. Ball in the service of the city, and we pay them all a tribute in paying this tribute to him.

NEW YORK CITY'S DEPARTMENT OF HOSPITALS

A NEW Department of Hospitals has been organized by Mayor James J. Walker of New York City which will begin to function February 1, 1929.

The bill was passed by both branches of the Municipal Assembly.

Under this plan all the hospitals controlled by the city will be reorganized. At present several are under the direction of the Department of Health; the Department of Welfare and another group are directed by the trustees of the Bellevue and Allied Hospitals. According to the new arrangement these three groups will come under the direction of one head to be known as Commissioner, whose appointment will be announced later.

Preceding the signing of the bill by Mayor Walker making this organization a reality there was a hearing in which representatives of several civic and welfare organizations participated.

PREVENTIVE MEASURES IN NEW MEXICO

IN Dona Ana County, C. W. Gerber, M.D., Health Officer, is directing a house-to-house canvass for the purpose of discovering all malaria cases and carriers in the county. This survey is made possible by a number of public health nurses added to the county health department's staff.

A toxin-antitoxin campaign is being carried on in Colfax and Mora counties under direction of the health officers, H. W. Heymann, M.D., and J. J. Johnson, M.D. They are aiming at the inoculation of every child who has not received previous treatment.

ABRAHAM FLEXNER LECTURESHIP

VANDERBILT University School of Medicine has recently announced the inauguration of the Abraham Flexner Lectureship, established through the generosity of Bernard Flexner of New York, N. Y. There will be delivered a series of 5 lectures, the first lecturer being Dr. Heinrich Poll, director of the Institute of Anatomy of the faculty of University of Hamburg, Germany.

PERSONALS

R. S. CRAIG has been appointed Director of the Bureau of Chemistry and Food, Baltimore, Md., to succeed Dr. J. H. Shrader, resigned. Mr. Craig has been with the Baltimore City Health Department for 15 years and for 6½ years has been assistant director of the bureau.

DR. CLAIR V. LANGTON, formerly a member of the faculty of public health, University of Michigan, has resigned to become head of the Department of Public Health at the University of Oregon.

DR. ALONZO F. MYERS, formerly a member of the executive committee of the Ohio Public Health Association, has accepted a position as State Director of Teacher Training in Connecticut. He will be in charge of four state teachers' colleges, and will direct the summer session of the state department, held at Yale University, New Haven, Conn.

DR. R. JODOROLA has been appointed city Health Officer of Los Banos, Calif., to succeed Dr. B. H. Bush.

DR. J. A. DE SERPA has succeeded Dr. Louis Achenback as city Health Officer of Ventura, Calif.

DR. H. W. COMFORT is city Health Officer of Fortuna, Calif.

DR. H. B. NEAGLE has been appointed Health Officer of Madera County, Calif., to take the place of Dr. Smith A. Quimby.

GROVER C. MULL of Menlo Park, Calif., has succeeded Clarence R. Walter as city Health Officer of Atherton, Calif.

DR. LEROY B. DUGGAN, Belton, Tex., has been made assistant director of health of the Dallas, Tex., public schools. He succeeds Dr. L. E. Hamilton, who resigned.

DR. ROGER I. LEE, professor of hygiene of Harvard University Medical School, Boston, Mass., has been made chairman of the committee on public

health of the Boston Chamber of Commerce.

DR. H. E. LEFEVER, formerly resident physician at the Franklin County Tuberculosis Sanatorium, Columbus, O., is associate director of student health at Ohio University, Athens, O.

DR. FERDINAND R. KREMBS has been appointed Health Officer for the city of Stevens Point, Wis.

SIR SAMUEL SQUIRE SPRIGGE, London, England, editor of *The Lancet*, is visiting schools of medicine in this country and Canada. Sir Samuel Sprigge expects to visit 8 universities in the United States and 2 in Canada before returning to England where he will make a report on medical education in this country.

DR. WILLIAM H. O'NEIL has been appointed Health Officer of Ansonia, Conn.

CONFERENCES

December 3-7, Radiological Society of North America, Chicago, Ill.

December 7-8, New Jersey Public Health and Sanitary Association, Princeton, N. J.

December 13-15, American Vocational Association, Philadelphia, Pa.

December 26-29, American Association for Labor Legislation, Chicago, Ill.

December 26-29, National Community Center Association, Chicago, Ill.

December 27-29, Society of American Bacteriologists, Richmond, Va.

December 27-January 2, American Association for the Advancement of Science, New York, N. Y.

December 28, International Congress of Tropical Medicine and Hygiene, Cairo, Egypt.

December 29, American Student Health Association, New Orleans, La.

January 22-23, Southwestern Tuberculosis Association, Ft. Worth, Tex.
